Carpets are made to the annual value of 3,500,000 fr., the larger part at Aubusson and Felletin, two towns in the department of the Creuse, employing 1800 hands, and producing goods to the value of 1,500,000 fr. Carpets are also made at Abbeville, at Amiens, Turcoing, and Besançon. The finest and richest velveted carpets, called "de Savonnerie," are made at Beauvais, and at the Gobelins in Paris. These are only made to order, and are not articles of traffic. The exports of woollen goods reach on an average the sum of 65,600,000 or 66,000,000 fr., consuming 2,578,487 kilo. of wool. They consist of coverlets, carpets, cloth, casimirs, and merinos, varied stuffs, shawls woven or made by hand, bonneterie, ribbon of worsted, and similar light goods, and stuffs of mingled materials. Machinery has been used for spinning wool in place of the hand only since 1809. Reims is the great centre of French wool-spinning, it being situated in that part of the country where sheep are most numerous. There are at Reims 275 establishments for spinning carded wool, and nearly 55,000 spindles, or 60 establishments, for combed wool. The number of workmen is 50,000. France annually exports woollen yarn to the value of 2,000,000 fr. and upwards. Neapolitan flannels, English flannels or "bolivars," circassiens, lastings, cloths, casimirs, merinos, mousseline-de-laine, cuir-de-laine, made at Cartres first in 1819, and poplins, are noted manufactures.

Cotton.

The cotton manufacture was introduced into Amiens in 1773, the raw material being supplied, not from America, but from the Levant, with machines procured from England. In 1784 a privilege was conferred on an inhabitant of Seine and Oise for a manufactory; and soon afterwards the manufacture passed to Rouen, St Quentin, Paris, Lille, and other parts in the north, extending with a rapidity surpassed only by that of England. At present, as for many years past, the great import of cotton is from the United States. In this great department of manufacture the French have only followed in the footsteps of Great Britain, whose machinery, after the lapse of a certain time, the French manufacturers have imitated; and though they have equalled the British manufacture in durability, they have generally been inferior in cheapness. This is, in a great measure, owing to the centre of the manufacture being at Rouen and Paris, places where the support of workmen, including the extra price of fuel, is not less expensive than in Lancashire. The districts most remarkable for the cotton manufacture are Alsace and Normandy. The manufacture of *cotton velvet* was begun at Amiens so early as 1765; and in 1784 M. Martin of Amiens obtained, under the title of "the first importer from England of machines invented there for spinning cotton," the authority to establish a cotton factory with special privileges. Nîmes is celebrated for its fine but not very durable cotton stockings. There are also manufactories of *bonneterie de cotton* at Besançon, Vitry, Bar le Duc, &c.

Cotton yarn is often made in a different place from cotton cloth. Paris and the northern departments are the chief quarters for the supply of the former article, which is sent in quantities to Rouen, St Quentin, and other places. In former years, cotton yarn used to be smuggled in great quantities from England; but this is now limited to the finer qualities. The cotton manufactures of the more substantial kind, called *bonneterie*, such as stockings and caps, are carried on in the Ardennes, in Normandy, and in the department of the Gard in Languedoc.

The average annual value of the importation of cotton for the five years antecedent to 1833 is calculated by M. Costaz[1] at about L.3,700,000. The cotton manufacture is prosecuted in many parts of France, and presents a great variety of fabrics and an extensive division of labour. In one place the weaving alone is followed; in other places the manufacture of threads, which are sold to those who weave them into cloth. Such is the case in the department Du Nord, which exports a great quantity of thread to the cloth manufacturers. In other places they bleach the linens, which are afterwards dressed and stamped. The workmen employed in the cotton manufacture were estimated 20 years ago at 260,000,[2] and they now amount to 355,000. Still, however, France is decidedly inferior to Great Britain in almost every branch of the cotton manufacture; and the consequence is, that as the importation of English cotton goods is prohibited, they are smuggled into the country in great quantities. Among these, the introduction of cotton twist is most extensive; and as the French mills cannot manufacture the higher numbers, from 170 to 200, which are required in the fabrication of bobbinet, it has been found impossible to repress the contraband importation of this article. "It makes its way," say the writers of the Report on the Commercial Relations between Great Britain and France, "both by land and sea, in spite of all interdictions, and to a continually increasing amount."[3] The English can be sold also at half the price of the French article, which presents an additional inducement to the smuggler. The annual value of the manufactures thus illicitly introduced was estimated in 1833 at L.500,000 sterling; but smuggling has been reduced more than a fourth since that time. It is difficult to estimate the amount introduced, but very experienced persons in the trade doubt if it much exceeds L.250,000. English bobbinet was also smuggled 20 years ago into France to the estimated annual value of L.625,000 sterling; but it is questionable whether the amount of illicit traffic now amounts to L.300,000, though English bobbinet sells at from seven to eight per cent. above the price of French goods of the same nominal quality. Quiltings, cambrics, and muslins are also largely introduced by the illicit traders; and the delivery of these goods is insured at a premium of from 18 to 50 per cent., according as the risk is greater or less in the case of heavy or of light goods. In 1852, 1,760,000 fr. were paid in bounties on *fils et tissus de coton*. The average wages of men employed in the cotton trade is 2 fr. 50 cen. per day; of women 1 fr. 20 cen.; children are paid 50 cen. The value of the cotton fabrics of Normandy is 105,000,000 fr., that of Alsace 80,000,000 fr. In the last district 70,000 hands are employed in weaving; from 12,000 to 15,000 in printing; and 1000 in the bleaching grounds. In Normandy and vicinity, including a part of the Somme, Pas de Calais, Aisne, Eure, and Manche, 129,000 hands are employed, namely, 60,000 weavers for the Rouennerie, 20,000 for the calicoes, and 49,000 in other divisions of the labour. Alsace produces principally cotton cloths for printing, and exports a part into Switzerland. The number of pieces of printed cotton and muslins made is calculated at 1,100,000, valued at 40,000,000 fr. They are of three kinds and prices, but are unable to cope in cheapness with the English. Tulles, at first made only in Normandy, are now manufactured wherever cotton fabrics are made; to the extent of 32,725,000 fr., of which 20,000,000 fr. is the cost of the embroidery. The most important of this branch of the manufacture is carried on at and near Calais, where from 600 to 700 looms, and 4800 men, women, and children, are in constant employment. The manufactures of muslins are most in arrears of all, owing to the fineness of the thread required, which is not yet made in France, but imported for the purpose. Tarare is the seat of this manufacture, valued at 20,000,000 fr. These muslins are generally embroidered. Blonds and lace are made at Caen, Bayeux, and above all, at Chantilly (Oise), where 70,000 persons are employed. Cotton *bonneterie* is made at Troyes to the value of 7,000,000 fr., employing 10,000 looms, and from 10,000 to 12,000 hands. Rouen is also noted for this manufacture. The exportation of cotton goods from France in 1840 reached 5,000,000 kilo., valued at 105,753,743 fr. The importation of cotton thread from England in 1853 was 90,002 kilo., in value 1,559,311 fr. That of raw cotton in 1839 was 40,534,278 kilo., in value 71,204,784 fr.; in 1840, 52,941,581 kilo., in value 94,005,975 fr.

The cotton manufactures of France consume between fifty and sixty million kilo. annually imported, valued at 94,005,975 fr.

Cotton wool in transit	57,191,970
Cotton thread used at home	1,218,034
Cotton thread in transit	383,356
Cotton cloth consumed in France	305,256
Cotton cloth in transit	34,413,978
	187,518,569 fr.

In 1803 the import of cotton wool had reached 10,711,665 kilo., and in 1820 had doubled that amount. The cost of the raw material in France, and its manufacture, are enhanced by the expense of fuel and carriage. The profits, deducting all outlay and wear and tear of machinery, and making allowance for every expense, are considered to be about 30,000,000 fr. It appears, that prior to the legal permission to import cotton thread free, when above No. 143, not less than 5,000,000 kilo. were smuggled, when the duty was from 70 to 80 francs the kilogramme. This traffic has not yet ceased. The spinners number from 80,000 to 90,000, and the mean wages of adults and children are 1 fr. 50 cen. per head, who attend to 3,500,000 spindles. No. 132 of the French thread corresponds to No. 120 of the English, because of the difference between the English pound weight and the French demi-kilogramme. In the year 1806 the utmost degree of fineness attained in cotton thread was No. 110. In the year 1809 it had reached No. 150. In general the French thread remains much below the English, but it continually improves. No. 180, which in France sells at 39 fr. or 40 fr., costs in England only 18 fr. In the Seine Inférieure at Rouen, and vicinity, there are about a million of spindles at work. In the arrondissement of Lisle 600,000 are worked by 82 steam-engines, of 850 horse-power in all. St Quentin works 210,000 spindles, with 200 horse-power of steam, besides water-power. The spinning in Alsace employs 18,000 persons of all ages. The dyeing of cotton occupies 87 establishments at Rouen and its vicinity alone. The principal part of the weaving takes place in Normandy, Alsace, Amiens, St Quentin, and Troyes. The looms are above 270,000, and employ 385,000 hands, the mean of whose wages is 75 cen. per day. Many of the looms there are worked by hand. The principal products are calicoes for printing.

In the departments of the Seine Inférieure, Somme, Pas de Calais, Aisne, Eure, and La Manche, the spinners, weavers, dyers, muslin fabricators, machinists, cardmakers, amount to 107,000. The individuals connected with the manufacture in other ways, the whole comprising 150,000 families, carry the total number concerned up to 400,000. Of the workmen immediately designated the number is 107,000, employed thus:—

Spinners	21,000
Machinists	5,000
Loom weavers	65,000
Dyers	5,000
Muslin fabricants	9,000
Cardmakers and others	2,000
Total	107,000

In Alsace, including the Haut and Bas Rhin, the Vosges, the Meurthe, Haute Saone, and Doubs, above 100,000 persons are employed:—

Spinners	17,000 to 18,000
Loom weavers	70,000
Printers	12,000 to 15,000
Bleachers	1,000
	104,000

The principal places for the manufacture of yarn in Alsace are Mulhausen, Wesseiling, St Mary aux Mines, and Guebwiller. In the other parts of France the principal are St Quentin, Rouen, Caen, Amiens, Bar le Duc, Lille, Roubaix, Turcoing, Lyon, Paris, Darnetal, Bolbec, Troyes, Gisors, &c. The yarn made in the Seine Inférieure exceeds the whole made in Alsace. In the departments of the Somme, Pas de Calais, Aisne, Eure, and Manche there are 60,000 weavers of *Rouennerie*, 20,000 of calico, and 49,000 in the other branches of the manufacture.

In the extent of her linen manufacture, France is greatly superior to England; not that her soil is better adapted to the growth of hemp and flax, but because England depends on importations of linen from Ireland and Germany, and the spinning of flax does not form the occupation of our female peasantry. In France, particularly in the north, every farmer, and almost every cottager, covers a little spot with hemp or flax to employ his wife and daughters in spinning throughout the year; a stock of linen being the usual dowry of these humble occupants of the soil.

The manufacture of this article is not exclusively concentrated in the towns, like that of the other fabrics: many of the weavers reside in villages and hamlets; and the hemp and the flax are spun by the hand. This is a most valuable branch of domestic industry,

Linen.

which gives employment to females under the roof of their parents; but it is destined, in the progress of capital and industry, to be superseded by machinery and great establishments. In Normandy, Lisieux, Dieppe, the neighbourhood of Havre, Yvetot, Bolbec, and the more inland towns of Vimoirtiers and Domfront, are all remarkable for one or more branches of the linen manufacture. The more backward province of Brittany manufactures, at Rennes, St Malo, and Vitré, quantities of coarse linen, canvas, and sacking; but Anjou affords a much superior article; the *toiles de Laval* have long been in repute, and give employment, in Laval and the contiguous towns, to nearly 25,000 workmen. Lille and its populous district have very extensive manufactures of hemp and flax; for the number of workmen so employed, directly or indirectly, in this part of French Flanders, is not short of 50,000. Since 1790, fine linen has, in France as in England, been in a great measure replaced by fine cotton; and the two together employ, at St Quentin (in Picardy) and the neighbourhood, more than 30,000 workmen. In another part of the kingdom, the province of Dauphiné, there are carried on linen manufactures of various qualities, the prices being from 1 fr. 10 cen. to 5 fr. the yard.

The value of the linen manufacture of France of every kind is no less than 525,000,000 fr. The raw material grown in France is valued at 30,941,840 fr. for the hemp, and 19,000,000 fr. for the flax. The hemp imported, and the thread together, give 35,699,003 fr. value. About 1,000,000 fr. is the worth of the flax imported. Total, 20,000,000 fr. The manufacture gives—

For the hemp	107,097,009 fr.
The flax........................	75,000,000
	182,097,009 fr.

The manufactures of hemp and linen employ 600,000 workmen. The exports of linen, principally to England, were, in 1840, nearly 6,167,731 kilo. The manufacture has doubled since the first Revolution. Lille, Dunkirk, Essonne, Pont Remy, Bellais, Vernon, and Alençon, are noted places for their linen manufacture. Normandy sends to Paris annually 20,000 pieces of linen. The linens of Brittany are mostly consumed at home. The fine linen cloths called *toiles de mulquinerie* are principally made in the departments of the Aisne and Nord. St Quentin was once noted for them; now that town, Cambray, Valenciennes, and Solesmes, produce cloths so fine, called *batiste* and *linon*, that 70,000 pieces are exported to England. The beautiful batist embroidery employs 13,000 persons at Nancy. *Coutils*, a cotton cloth crossed with thread of linen, are woven in the department of Mayenne, where 4500 looms are employed upon this article.

French linen differs in quality according to the place of manufacture; but in general it is thicker and stiffer than Irish linen, whilst in whiteness it is inferior to the linen of Flanders and Holland. It is, however, a substantial and durable article.

Cambrics, thread, gauze, and lawn, rank among the leading manufactures of the north-east part of France. They are made at St Quentin, Valenciennes, Cambray, and to a smaller extent at Douai, Chauney, and Guise. Lace is still more general, being made in quantities at Valenciennes, Dieppe, Alençon, Caen, Bayeux, and Argentan. Machinery had, up to 1820, been very little applied to this manufacture in France, and the number of women employed in it was very great. There are considerable manufactures of printed linens; and the dyeing of linen thread gives rise to an extensive commerce. At Rouen, and in the surrounding districts, this branch of industry is carried on; and many stuffs of great variety, and for which there is a brisk demand, are produced. In 1822 the duties on foreign thread and linen were raised by the French government till they were nearly prohibitory; and the annual importation from Germany and Belgium, which formerly amounted to a million and a half, almost entirely ceased. The price of home-made linen rose 25 and 30 per cent.; the consumers had recourse to cotton as a substitute; the French dyeing trade fell off, and also the entrepôt trade in foreign linens, both of them sources of great business.

The value of the hemp annually grown in France may be computed at L.1,200,000, the quantity imported at L.200,000; together L.1,400,000; a value which is doubled in the coarse manufactures, and tripled in the finer. Of this quantity of hemp, the half is made into canvas and thread, a third into cordage, and the remainder into cloth for domestic use. Of the flax annually employed, the value is about L.800,000; a sum which is tripled when it is made up into thread, linen, and mixed stuffs, and much more than tripled in the finer qualities.

Iron.

France had in 1855 about 569 furnaces, of which more than 300 are said to be blast-furnaces. It is, however, almost impossible to ascertain the exact number of blast-furnaces, the position of which is regulated by that of the iron mines. They are chiefly in the mountainous departments of the Dordogne in the south-west, and of the Haute Marne, the Haute Saône, and the Côte d'Or, in the east of the kingdom. Of forges for malleable iron, called *forges à la Catalane*, there are eighty-six scattered throughout different departments, but chiefly in the hilly part of Languedoc. There are also a number of wire-works in France, in which, as in the blast-furnaces, there has been since 1790 a progressive but very slow increase, altogether different from the rapid advance of the iron-works of England previously to 1815.

The stationary character of these works has evidently been owing to the deficiency of fuel and of water communication; disadvantages which prevent the hardware manufactures from being concentrated in cities or populous districts, and cause them to be spread over the country in petty towns or villages, with a very limited division of labour, and a consequent inferiority of execution. The result is, that France does not export hardware, and that in nothing is the inferiority of domestic accommodation in that country more conspicuous than in articles which belong to the province of the locksmith and cutler. The amount of pig-iron annually made in France appears to be about 100,000 tons.[1] The value of the hardware of the kingdom, including cutlery, arms, and other articles of nice workmanship, is computed at L.8,000,000 or L.9,000,000 sterling. Fine cutlery in former times was largely smuggled into France, but now to a much smaller extent. The annual import of iron and steel[2] is only from L.2,000,000 to L.3,000,000. The high price of iron is a great obstruction to the progress of the hardware manufactures; and this circumstance places in a strong light the impolicy of the heavy duties on foreign iron, by which, notwithstanding the change in the scale of duty in 1838, all those important branches of industry in which iron is used are stunted in their growth. In copper, the importations greatly exceed the home produce. From Great Britain the quantity imported for the last ten years has increased from 200 to 20,000 hundredweight. Of lead, also, the chief part is imported. The manufacture of steel has only been lately introduced into France. Prior to 1786 there was no manufactory of this useful article; and it was only after accounts had been published by scientific persons of the composition of that article, and after repeated experiments, that in 1809 manufactories of steel were established, which have been since extended to several departments, especially to those of the Loire.

Silk.

As regards silk, France possesses, both from physical causes and from the long-established manufacture, a decided superiority. Mulberry trees were introduced in the fifteenth century, and were first planted, not in the south, but in the central part of the kingdom, near Tours. That town was the seat of the earliest silk manufactures, and it was not till 1600 that the culture of the mulberry was carried southward.

The mulberry thrives in a variety of soils, and may be planted with success in neglected borders or in waste lands. The labours of the silk-worm last only six weeks, after which the cocoons are in a state to be purchased for winding or carding. These processes reduce the quantity so much that the produce of an average year does not exceed 560,000 lb. *soie grege*, worth 20s. or 21s. the lb.; and 322,000 lb. organzine silk at 25s. France has not, however, sufficient silk for her own manufactures. She imports silk from the Levant (chiefly Persian silk), from Italy, Sicily, and Spain.

The cost of manufacture nearly doubles the value of the

---

[1] In 1846, 30,000,000 of metrical quintals were extracted from the iron mines, which were worth 7,800,000 francs, or 260 francs per metrical quintal. In 1836 the total weight of iron extracted amounted only to 20,000,000 of metrical quintals, which was worth 4,386,000 francs, or 217 francs per metrical quintal. In 1846 there was manufactured 5,224,000 metrical quintals of cast-iron, worth 80,500,000 of francs, or 15·30 centimes the metrical quintal. The manufacture of cast-iron and "gros fer" in 1846 amounted to more than 41,000,000 francs, and in 1836 of 20,000,000 only.

[2] The manufacture of steel in France in 1846 rose to 129,549 metrical quintals, worth 78 francs 12 centimes the metrical quintal; in 1836 it was 59,454 metrical quintals, worth 70 francs the metrical quintal.

Statistics.

raw material in the plainer qualities; and in the highly finished, such as fine ribbons, it may be said to triple it.

The manufacture of silk is considered as an important branch of French industry, not only on account of the variety and beauty of the fabrics, but because the raw material is an indigenous product of the country. It was estimated,[1] twenty years ago that the amount of the annual sales to foreigners was thirty millions of francs; that the home consumption of the kingdom amounts to L.3,333,334; and that the whole annual value of the silk manufacture was equal to L.4,598,889. The manufacture of silk is not confined to any particular spot. It is carried on in different parts of the country, in all of which it diffuses prosperity. It has enriched the poor of Nîmes, of Avignon, and of Tours; St Chamond and St Etienne owe a great part of their prosperity to the manufacture of ribbons, and the town of Ganges to bonneterie; Paris derives immense profits from her manufactures of silk stockings, and other fabrics, either of silk or with a mixture of silk, or of wool and cotton. Silk is also the great staple manufacture of Lyon, in which it is carried on in all its branches with astonishing success; and since the Revolution, in addition to fabrics of silk, all sorts of stuffs mixed with silk, and with cotton and wool, have been manufactured; and to these manufactures Lyon is indebted for its riches, having risen not only to be the second town of France, but one of the most opulent and flourishing cities in the world. It was twenty years ago estimated that about 60,000 or 70,000 individuals, young and old, were supported by the silk manufacture in Lyon and the adjacent district; but the number has increased 25 per cent. since 1835. The dyeing of silk being an important branch of the manufacture, many experiments were made to bring it to perfection; and, in particular, a dye of perfect black that would retain its colour was a desideratum. This dye was invented by a common dyer at Lyon, who received a pension, besides being made a member of the Legion of Honour. Prior to this the black dye which was used changed in a few days to a brown, and came off the stuff when it was hard pressed by the hand. Another improvement which was made consisted in procuring a silk of a permanent white colour. The eggs of the worm which produced this silk were brought from China, not, however, with the desired success. The worm was afterwards purchased from a merchant of Alais, and distributed in the northern departments of the country; and the produce of white silk is now very considerable, and of great importance in the manufacture of gauzes, crapes, and tulles. Other inventions were devised for saving labour in the various stages of the silk manufacture, by which, in this branch of industry, France was long enabled to outstrip all her neighbours, though of late years the silk manufacture has made immense advances in Great Britain.

There were in 1820 no less than 9,631,624 mulberry trees in France for the nourishment of the silk-worm. These supplied food for cocoons producing in 1819, according to Chaptal, 5,147,609 kilogrammes of cocoons. In 1835 the product had increased to 9,000,000, yielding 278,000 kilo. of silk grège, and 161,000 kilo. organzine. At present (1855) the quantity of silk furnished amounts to 1,600,000 kilo.; which, at 55 fr. per kilo., the average price, gives a sum of 88,000,000 fr. as the value of the amount produced. In 1810 the amount was only 4,073,198 kilo. of cocoons, at 3 fr. 45 cen. per kilo. In 1830 it had risen to 9,007,967, at 3 fr. 82 cen.; while the wound silk (grèges filées), which in 1810 only reached 350,629 kilo. at 45 fr. 12 cen., in 1835 had increased to 876,016 kilo., at 58 fr. 64 cen. per kilo. But the home growth not being enough to meet the demand, importations took place to the extent of 1,154,956 kilo., valued at 53,731,538 fr., and they still increase. Italy, Switzerland, Turkey, and Greece, supply the larger part; a small quantity is obtained from Austria and Sardinia. The exportation of silks, plain and flowered, from 1787 to 1789, on a mean of ten years, was 37½ millions of francs in value. In 1829 it was 111 millions, and in 1836, 206½ millions of francs, consisting of 2,720,914 kilo., under twenty-two different denominations of goods. The United States, England, Germany, then Belgium, and lastly Spain, are the principal outlets for the silks of France; but South America, Russia, and Switzerland, are also considerable purchasers. France exports silks to a large amount in the way of transit. Lyon, Avignon, Tours, and Nîmes, are the principal seats of the manufacture of silk stuffs; and St Etienne, St Chamond, and Paris, for that of ribbons. In the arrondissement of Lyon, and Ville Franche, there are 31,083 looms. The manufacture of ribbons at St Etienne employs 20,000 workmen and 30,000 looms, producing 27,473,000 fr. value annually. The fabrication is divided into the manufactures *unis* and *façonnés*. Under the first head are those with the prefix *gros*, as *gros de Naples;* those called *pou de soie, fontard, crêpes,* which last are subdivided; then satins and the like. The ribbons are in like manner distinguished by different appellations, after the nature of the fabric. St Etienne employs in all 279,000 spindles (*broches*); of which 165,000 work organzines and trames, and 114,000 work the silk intended for crapes and gauze ribbons. The number of looms has been estimated in all at 65,000 for wearing silks, and 80,000 for ribbons.

The raw silk or silk-wool consumed in France in 1840 was valued at 53,731,536 fr.; while the value of the silks in transit reached 40,134,301 fr. Plain and flowered silk consumed at home, = 5,299,490 fr.; that which passed in transit = 37,204,483 fr.: being a total of 136,369,810 fr. A decree of the 18th August 1852 permits the free exportation of silk.

The silk-wool of French production exported in 1840 was valued at 3,738,103 fr.; the foreign grown silk-wool exported at 47,491,154 fr. The value of the export and import together was thus 380,256,696 fr. The following are the most important districts of the mulberry, with the growths respectively, and the cocoons produced in 1840:—

	Hectares.	Kilogrammes. Cocoons.
Gard	14,941	2,696,000
Drôme	6,212	2,585,352
Ardèche	5,602	1,765,121
Vaucluse	3,986	660,600
Hérault	2,592	1,248,972
Isère	2,073	539,507
Bouches du Rhône	1,546	549,780
Rhône	1,295	471,560
Ain	836	74,716
Var	787	491,750
	39,770	11,053,358

About 500,000 kilo. of cocoons are produced in the other departments. The importation of English woven silk into France in 1853 was 52,703 kilo., in value 5,464,699 fr.

Articles of leather are in France much cheaper than in England.

Jewellery, porcelain, &c.

Jewellery is made in Paris to the value of 50,000,000 francs. Lyon, Marseilles, Bordeaux, Clermont, and Strasbourg, are also famous for jewellery. Watch and clock making are carried on to a great extent in France, particularly at Paris. A timepiece is there a much more frequent article of ornamental furniture than in England, and the number of clocks and watches made annually in the kingdom is not less in value than 30,000,000 francs, employing 10,000 hands. The works in bronze are chiefly manufactured in the capital, and reach in their different branches and stages, of which gilding is the chief, a further annual value of 37,000,000 francs.

Paris is remarkable for other fabrics of taste and luxury; in particular, the porcelain of Sevres, near St Cloud, and the beautiful but very expensive tapestry of the Gobelines. The materials of the latter are silk and the finest woollen thread; the subjects woven into the work are taken from paintings executed on purpose. Both the establishments have been long conducted by government at a sacrifice, and both are now on a reduced scale, the articles being far too costly for ordinary fortunes. The articles more frequently purchased are *passementerie*, by which is understood artificial flowers, fringes, gold and silver lace, with a variety of trifling but tasteful articles, all sufficiently adapted to a city where so much more is thought of display than of utility.

Soap.

The value of all the soap made in France is computed at 30,000,000 francs. The main ingredient is olive oil; and Marseilles was formerly the seat of this manufacture for almost all France—an advantage owing both to the extent of the olive-grounds in the south-east of the kingdom, and the vicinity of Marseilles to Italy, the Levant, and Spain, whence soda and olive oil were imported in vast quantities. A million of francs were paid for bounties on the export of soap in 1852. The export of soap from France in 1838 was 2,911,631 kilo., valued at 2,941,631 fr. The disorders of the first Revolution, and the establishment of similar manufactures in other parts of France, have caused to Marseilles the loss of a third of its soap works; they are still, however, very extensive. Of the oil used in France, whale oil forms a very small proportion; the great supply is of vegetable oil,

Oil.

---

[1] See Costaz, *Sur l'Agriculture et les Manufactures de France.*

viz. that extracted from the rape and cole seed of the north, and the olive oil of the south.

Liquors.

Beer, formerly little drunk in France, has become of extended consumption since 1790; but even at present the quantity used does not exceed L.2,000,000 sterling, its place being supplied by cider in the north, and by wine in the south. Within the last few years there is a considerable consumption of English bottled stout and porter, and a lesser though increasing consumption of English ale. The breweries have increased and are increasing in Paris as well as in the northern departments. The consumption which corresponds to that of our home-made spirits, and our rum, is in brandy, of which the value annually made is between L.2,000,000 and L.3,000,000 sterling. The distillation varies in amount with the season. The brandies of Cognac, Jarnac, and Angoulême, are most in esteem. The best brandy is made in a district called Champagne, comprehending a part of the Saintes, Jonzac, and Cognac territory. In Franche-Comté and Alsace a brandy called Kirsch is made, but little of which is exported. The Hérault, Aude, and Gard, supply the largest quantity of spirit of wine. The best is called that of *trois-six*. The amount varies from 40,000 to 80,000 pipes of 80 veltes, 5 of which form a quintal. A velte is 7·61 litres = 1·675 gallon. Beer is brewed in the northern and eastern departments, viz.:—

	Quantity.		Value.	
Nord Oriental	3,115,615	hectolitres.	41,419,432	fr.
Nord Occidental	527,378	do.	9,429,261	„
Midi Oriental	160,942	do.	5,447,719	„

Cider is made everywhere, in largest quantity in the Nord Occidental, and the best in La Mancha and Calvados. Some is distilled for brandy. The quantity is estimated at 11,000,000 hectolitres, at 7 fr. 75 cen. Normandy furnishes half. The whole is worth 34,000,000 fr. There is also a considerable distillation of spirit from potatoes; which, says Chaptal (vol. ii., p. 197), has been generally approved, and has been brought into competition with brandy.

Lesser manufactures.

Of hats, the manufactures, formerly concentrated at Lyon and Marseilles, are now diffused throughout several towns; and the value annually made is about twenty-four millions of francs. The hat manufacture of Paris is estimated at an annual production of 1,200,000, of the average value of 5 fr. each, and employing 2000 men and 2500 women. Superior qualities of silk hats are sold to the retail tradesman at from 9 fr. to 11 fr., for which the latter obtain from 15 fr. to 18 fr. The hat manufacture in France employs 17,000 hands, and yields a value of 19,500,000 fr., in 1159 workshops. The second order of hatters, who finish the hats according to the different tastes required, elevate the value of the trade to 24,375,000 fr. The manufacture of gloves—principally made at Grenoble, though called "Paris gloves"—employs 25,000 persons. In 1839 the value of the gloves made in France was 9,436,000 fr.; in 1840, 5,556,000 fr. The tanneries prepare 33,286,004 kilo. of leather, valued at 82,864,706 fr., for boots, shoes, saddlery, &c. Perfumery is made extensively in Paris, and in the south, chiefly at Montpellier, where, from the mildness of the climate, aromatic plants are abundant. The value of the manufacture is about 13,000,000 fr. Paper being exempt from the heavy duties of England, is sold in France upon very reasonable terms, whilst in quality it is equal to our own. The value annually used in printing and in writing is computed at 25,000,000 of francs, and the paper employed in the hanging of rooms is estimated at an equal value. Of glass, the manufacture has been much improved and extended during the present age. Whether for mirrors, for windows, or for bottles, this article in France is good and of a moderate price. The number of glass-houses in 1818 was 185, and is now over 220. Small mirrors are manufactured much cheaper in France than in England. Bohemia is the country with which the French manufacturers state they cannot compete. As to earthenware, it is only since 1790 that English pottery has been successfully imitated in France. It is now made to the value of 29,000,000 fr.; whilst the coarse earthenware, fabricated in almost every province of the kingdom, is computed at 15,900,621 fr., employing 10,433 hands. French earthenware is very inferior to English.

Saltpetre, till lately a monopolized manufacture, is now unrestricted. Sulphuric acid has, since the beginning of the present century, been greatly lowered in price and increased in quantity.

Sugar.

The manufacture of sugar from beet-root was introduced into France during the reign of Napoleon Bonaparte, when, the coasts of France being blockaded by the fleets of Britain, the importation of foreign articles, and among others that of sugar, was rendered dangerous and difficult; and its price was so high as entirely to preclude its consumption by the middle classes of society. Various articles were resorted to as substitutes, such as honey, the juice of raisins, &c., but they were not relished by the taste of the people; and in this case experiments were tried by eminent chemists to extract from beet-root the sugar which it contained. These experiments were successful. There were in 1831 more than 200 establishments, from which were produced annually 7,480,000 lb. of raw sugar; and there were in 1854 303, producing 62,205,600 lb. The largest sum paid by the administration of the customs has been for refined sugar. It amounted in 1852 to sixteen millions of francs.

Machinery.

The manufactory of machinery has greatly increased. Steam-engines have been introduced into France from Great Britain, where they are now employed in every department of industry. It was in the year 1779, at the village of Chaillot, near Paris, that the first steam-engine was established in France; but, owing to prejudices, and attachment to old customs, it was long before these engines came into very general use. Prejudice, however, gradually faded away before the productive powers and manifest utility of this extraordinary application of science to the business of life, and there are now many establishments for the manufacture of these machines. The scarcity of coal is a great obstruction to the extensive use of steam-engines; and the tax on foreign coal is in this view peculiarly impolitic, and injurious to the general interests of the community. The tax, though lately reduced by the imperial government, requires still further reduction.

In 1836, of 1749 steam-engines in France, 1393 were home made. In 1839 the import surpassed the export. Since that year the reverse has been the case. The metallic castings in France are still very inferior to those of England. Paris is the principal seat of the manufacture of French machinery, then Arras, Creuzot, Rouen, Mulhausen, and Nantes. Locomotive engines are made at Bitschwiller in the department of the Haut-Rhin; machinery for steam-vessels at Indret.

The value of French industry has been estimated in the mean product as follows:—

	Francs.
Iron from the ore to the perfect state, minerals, &c.	124,000,000
Copper, zinc, and lead	26,500,000
Glass, crystal, and looking-glasses	47,500,000
Tiles, bricks, lime, plaster	66,500,000
Porcelain, pottery, &c	27,500,000
Chemical manufactures, the products	22,000,000
Hemp and Flax (supposed to be no less than 525 millions of francs)	360,000,000
Cotton	500,000,000
Wool	400,000,000
Silk	230,000,000
Leather and skins	300,000,000
Sugar	45,000,000
Paper, coloured and figured	25,000,000
Printed paper, books, &c	25,000,000
Machinery	10,000,000

	Francs.
Clocks and watches	30,000,000
Bronzes	25,000,000
... plated ware	6,000,000
... jewellery and goldsmith's work	50,000,000
Distilleries, breweries	206,000,000
Different branches of industry	135,000,000
Mechanics and domestic arts	250,000,000
L.116,440,000 =	2,911,000,000

General observations.

Labour in Paris is as much dearer relatively to the provincial towns of France, as labour in London is relatively to those of England. It still remains for us to remove from our capital some manufactures which have been most injudiciously established there; but the French have carried this false calculation much further, Paris being the centre not only of ornamental fabrics, such as jewellery, bronze, sculpture, cabinet-making, and the vast variety of elegant trifles comprised under the term "articles de Paris," but of a number of coarser employments, which a very slight change of plan might transfer to a cheaper quarter. Periodical exhibitions of French manufactures are held at Paris every three or four years, at which are present the sovereign, the princes, the nobility, and all eminent men of science. In 1855 was opened in Paris an Exhibition of the Industry of all Nations, similar to that which took place in London in 1851, and in Dublin in 1853. The Parisian exhibition, like the Dublin one, contained a branch dedicated to the fine arts. This exposition continued open from May till the middle of November. It was twice visited by her Majesty Queen Victoria between the 20th and 25th August in her nine days' visit to France. There is also in that capital a *Conservatoire des Arts et des Métiers;* a collection, on a large scale, of models of all instruments or machines that relate to arts and manufactures. It is more the practice also in France than in Britain to encourage ingenious inventions in the mechanical arts, by premiums, orders of merit, and other honorary marks of distinction. Yet, with all these advantages, industry has not made the same progress as in this country.

To prescribe the mode of manufacture was formerly a favourite course with government in England as in France. From the time of Colbert (1660) the French *ordonnances* prescribed peremptorily the length and breadth of serges, of druggets, in short, of every kind of cloth calculated for export, under the plausible idea that all these precautions were necessary to establish a reputation for quality. It is a curious fact, that these rules were desired by the manufacturers themselves, and were long considered as the safeguard of French industry. A change was introduced in 1779, and permission given to every manufacturer to follow his own method, provided he distinguished the goods thus made from those which were in conformity with the regulations. But this was of very short duration. The power of habit and prejudice prevailed. New *ordonnances*, issued the succeeding year, revived the former limitations; and the manufactures of France were not put on an unrestricted footing till the Revolution. Much inconvenience had also been sustained from the absurd law which prevented a workman from settling in business in any town excepting that in which he had served an apprenticeship. This law was abrogated in 1767.

The manufacturing industry of France is confined, far more than ours, to the home market, whether we look to the supply of the raw material, or to the export of the finished articles. Her imports are large only in cotton and silk; in wool and iron they are not considerable; whilst in flax, hemp, and leather they may be termed insignificant. In exports the limitation is still more striking, her hardware, her linen, her woollens, her cotton, her leather, and, in a great measure, her silk, being confined to the home market; a restriction owing partly to our manufacturing superiority, but more to the capital of our merchants their ability, to give long credit, and to deal with foreign traders and merchants in a liberal and not in a petty retail spirit. The productive industry of France is consequently much less subject than ours to sudden fluctuation. It follows nearly the same routine year after year. On the occurrence of a war, or other political change, the commerce and manufactures of our neighbours, to borrow a phrase of Talleyrand (Letter to Mr Fox, 1st April 1806) *se replient sur eux-mêmes.*

VII. COMMERCE, COLONIES, FISHERIES, SHIPPING.

Commerce.

In no country in Europe has trade been laid under such galling restrictions as in France; and it is remarkable that this system of restriction has in a great measure been the creation of modern times. The ancient legislation of the kingdom was rather friendly to foreign trade. It encouraged importation in preference to exportation. This latter privilege of export was in 1577 claimed by Henri III. as his royal and seignorial right; and he regulated by his ordonnances the export duty on a variety of articles, whilst the produce of foreign countries was admitted on payment of an *ad valorem* duty of two per cent. Louis XIV. introduced a sort of navigation act, by which he levied a tax of fifty sous on all foreign ships. In 1667 further restrictions were introduced; and in 1687 the exclusive system was established in its full rigour. The statesmen of France seem to have imagined that a flourishing commerce could be created by legal authority, and that domestic industry could only be encouraged by the exclusion of all foreign competition; and hence all the vices and obsolete maxims of the mercantile system will still be found in the commercial policy of our neighbours. The extension of the restrictive system was promoted by the authority of Colbert, a minister who, though he introduced order into the finances, and improved in many particulars the system of taxation, and was indeed a great master of detail, adopted the most erroneous maxims of commercial legislation. It is justly observed, in the Report of Villiers and Bowring on the commercial relations between Great Britain and France, that the "whole of the bounties by which he induced adventurers to enter into remote speculations, as well as the excessive duties which he imposed on cheaper foreign articles, were almost uncompensated sacrifices; while, on the other hand, of the manufactures which he transplanted into France, and which he protected by the exclusion of rival productions, scarcely one took permanent root;" and even those which he intended to support by special encouragement would all of them have been more prosperous, but for the regulations with which his mistaken zeal retarded the progress of manufacturing industry. His whole system was an attempt to regulate by law what would have been better left to the sagacity of individuals, and to give a forced and artificial direction to the national capital. Thus he encouraged a trade to the West Indies by granting a bounty of 25s. on every ton of goods exported, and of 41s. 8d. on every ton imported. He boasted of setting up 40,000 looms by virtue of legal enactments, without considering that the capital employed in these establishments would have taken a more natural direction, and been more profitably employed, but for his interference. The restraints also which were thus laid on domestic industry were often enforced by the despotic authority of the government. Many of the absurd and pernicious regulations of Colbert were broken down by the first French Revolution; but others remained, and the tariff of 1791 was from beginning to end a system of prohibition, the object of which was to encourage the home manufacturer by freeing him from all foreign competitors. It must be confessed that England set the example of illiberality; and it was no wonder that the French of that day should be jealous of a country which excluded her silks and cambrics, and laid a discriminating duty of 33½ per cent. on French wines; and whose parliament, under the reign of William III., declared the trade with France to be a nuisance. The commercial treaty concluded with France in 1786 by Mr Pitt, was the earnest of a better system. Since this period the legislators of this country have been impressed with the injurious tendency of all commercial restrictions. But in France the progress of improvement has been slower, and it has besides been retarded by political events. The long and sanguinary war waged between Great Britain and France subjected the latter to the maritime hostility of her powerful opponent, the consequence of which was, that her trade with foreign countries was interrupted, and the supply of many of their staple articles of produce greatly diminished, and raised enormously in price. It became a great object, in this case, to produce these articles at home. In addition to the existing restraints upon the importation of foreign manufactures, special encouragements were given to the production of articles for which neither the soil nor the climate of France was peculiarly fitted. Thus when the maritime blockade of France was raised by the peace of 1814, her industry, partly from ancient and mistaken maxims, partly from the pressure of war, received a very artificial direction, and was oppressed by ruinous and complicated restrictions. At the restoration of the Bourbons in 1814, the tariff of 1791 was the law of the land. It had undergone a few modifications, but these were mostly in the restrictive and prohibitory spirit, and were accommodated to the hostile position which France occupied in regard to surrounding nations. When the barrier to a free intercourse with foreign nations was at length thrown down by the peace of 1814, the exclusive provisions of the tariff of 1791 were brought into full operation; and when the obstacles to the commercial intercourse of France with foreign nations raised up by the war were withdrawn, a no less effectual line of circumvallation was drawn around her commerce by the restrictions and prohibitions of her own erroneous policy. It is remarkable, indeed, that a committee of the Chamber of Deputies, in reporting on the budget in 1832, enters into an exposition and defence of the restrictive system, the principle of which is to encourage domestic industry by the exclusion of the cheaper and better manufactures of foreign nations.

The tariff of 1791 either excluded from France, or laid under heavy duties, almost all the great staple manufactures of other countries. Manufactured iron in every shape, manufactured steel, copper, tin, cutlery, and all articles manufactured from any of the metals; all fabrics of wool, cotton, silk, or tissues of hair, saddlery, spirituous liquors, grain, refined sugar, tobacco, toys, and various other inconsiderable articles, are included in this charta of domestic commerce. The inconsistency, and the fallacies on which this system is founded, are well exposed in the Report of Villiers and Bowring. The passage, though somewhat long, is replete with instruction.

"It requires merely to state some of the objections to importations, in order to show their narrow and anti-commercial spirit. The introduction of manufactured tin, for example, is opposed because it might benefit England, which is rich in tin mines, as if the importation into France could take place without equally benefiting her. The reasons, too, which are grounded on the superiority of other countries; as, for example, 'dangerous rivalry' in the case of manufactured steel; 'cheapness' of foreign article in the case of shipping; threatened 'annihilation of the French manufacture' in that of cutlery; 'extra advantages of the English' in plated ware; 'apprehension of the English' in articles of pottery; 'imprudence of admitting English saddlery,' as so many persons, regardless of price, prefer it; 'advantages of machinery' in works of iron; all are modes of announcing the superiority of the foreign articles, and the power which foreigners possess of supplying them on cheaper terms than they can be produced at home.

"There are other grounds of prohibition by which particular French manufactures are avowedly sacrificed to the interest of other branches of French industry. The importation of extracts of dyewoods is disallowed for the purpose of encouraging the importation of the dye-woods themselves; the interest of the dyer, the manufacturer, and consumer, being wholly forgotten. The importation of iron of certain sizes is prohibited, lest small manufacturers should establish fabrics, and supply the markets at a less cost than the larger establishments. Woollen yarn is not allowed to be imported, because it can be produced in France, though the high price must be a great detriment to the woollen manufacture; and cast iron of a great variety of sorts is prohibited, on the ground that a sufficiency may be obtained at home, though the cost is notoriously more than double that of many articles of foreign cast iron. Molasses are not allowed to be introduced, because the price in France is so low, and the exportation so large, on the ground that importation will lower the prices still more, though the lowness of price would obviously make importation unprofitable; and the fact of considerable exportation is the best evidence that the average prices are low in France. Rock salt was prohibited in 1791, and the prohibition is now justified on the ground that mines have lately been discovered. The prohibition of refined sugar was supported on the ground that its admission would not benefit the treasury; but it is clear, if the interest of the treasury were kept in view, that all prohibitions would be suppressed, or superseded by a system of duties. While some articles are prohibited because the production is small in France, and requires protection, others are prohibited (dressed skins, for example) because the production is great, and engages a large number of hands."

There is another branch of the French legislation regarding commerce, which is equally exceptionable with the prohibition to import foreign manufactures; namely, the system of drawbacks and bounties on the exportation of domestic produce. Having by special encouragements created a surplus of certain articles at home, and which the high price prevented from being sold to foreigners, the public were called upon to pay the difference between this high price and the price abroad; and thus they were taxed, by the exclusion of the foreign article, in a higher price for what was consumed at home, and also taxed for all that was consumed abroad, in the bounty which was paid on the exportation of the article. This is a double iniquity, which has gone on increasing in France. In 1817, the whole amount of what was conceded on this account amounted to L.3500 per annum, whilst in 1830 it amounted to L.600,000, nearly one-fifth of the nett amount of the whole customhouse revenues of France; and as it was going on progressively, it might soon have absorbed the whole customhouse income, without in the least benefiting, but rather injuring, the general interests of commerce. During the first nine months of the year 1832 premiums or bounties were paid to the amount of 24,448,375 francs, or L.1,018,682.

The commerce of France, obstructed by these restrictive duties, has not made the same advances as her agriculture and manufactures. The internal produce of every country necessarily increases with its population; and the inhabitants of France having increased, since 1780 to 1855, to full 36,000,000 (for the census of 1851 makes the population 35,781,628) from 24,800,000, must produce as well as consume more. But in the mean time her commerce has not kept pace with this increase in her population. The value of the imports into France amounted in 1787 to 631,790,700 francs, or about twenty-five millions sterling, and engaged 888,868 tons of shipping; and her whole imports only amounted in 1830 to twenty-five and a half millions sterling, and employed 1,009,454 tons of shipping, which is far from being an increase corresponding to her augmented population. According to the last accounts, the value of imports was in 1853, L.65,240,000, of which to the value of L.44,120,000 remained for home consumption, and engaged 4,605,000 tons of shipping. The whole trade of France with its own colonies and foreign powers amounted for the year 1853 to an official value of 3443 millions of francs, which was an increase of 12 per cent. on the year 1852, and an increase of 32 per cent. on the average of the years between 1844 and 1848. The foreign commerce of England was, in the year 1787, about seven millions less than that of France, or about eighteen millions sterling, and employed 1,349,419 tons of shipping. Her population was nine millions. In 1830 her foreign trade had increased to L.69,700,748, including L.17,127,764 to the colonies, which employed 2,860,515 tons of shipping. Thus, whilst the official value of the commerce of England had nearly quadrupled, and her shipping nearly doubled in forty-three years, not above one-fiftieth part was added to the foreign commerce of France; a fact which strongly illustrates the pernicious influence of monopolies in damping the energies of individual enterprise, and thus obstructing the national prosperity.

Official value of Imports and Exports.

Years.	Imports. Fr.	Exports. Fr.
1849	1,142,000,000	1,423,000,000
1850	1,174,000,000	1,531,000,000
1851	1,158,000,000	1,629,000,000
1852	1,438,000,000	1,682,000,000
1853	1,632,000,000	1,861,000,000
Total	6,544,000,000	8,126,000,000

The intercourse of France with its colonies and foreign states in 1853, exports and imports united, formed a sum in official value equal to 3,493,000,000 francs, being an augmentation of 373,000,000 francs over 1852. The actual value of the imports in 1853 was 1,217,000,000 fr. against 1,006,000,000 fr. in 1852, and of the exports the actual value was 1,572,000,000 fr. against 1,278,000,000 fr. in 1852. The ocean imports were in actual value 1,070,000,000 fr., and those by land 626,000,000 fr. The exports by sea were 1,633,000,000 fr. actual value, and those by land 420,000,000 fr.

The following tables will be found to contain, from official documents, a comprehensive view of the value and extent of the commerce of France at different periods.

Observations on the trade tables of France.

During the four years from 1850 to 1854 inclusive, the value of French commerce has augmented 303,329 francs, and the number of seamen employed has increased 19,046. The exports to Russia, owing to the war, were reduced in 1854 to three outward-bound vessels. The commerce with England has increased with great rapidity, having nearly doubled the amount in 1850. With Sweden and Norway the increase has also been considerable. With Austria, on the other hand, there has been a diminution, and also with the Roman states. With China there is an increasing trade, as well as with the United States of America, but with Rio de la Plata and Ecuador there has been a falling off. Most of the other states with which France carries on a commercial intercourse exhibited an increase which, if small, augmented the general commerce so much as to show that the country was entering upon a more active career of traffic

Statistics.

than she has exhibited since the revolution. The intercourse of France and twelve of the great European states increased considerably between 1852 and 1853.

Mercantile intercourse of France in 1852 *and* 1853 *with twelve of the most important states* :—

Iron, pig	15,002	26,416
Iron, bar	1,841	...
Steel	270	...

Returns of the customs duties levied on the principal merchandise imported into France during the nine months of 1855, ending on the 1st of October, give an amount of L.5,927,030. Compared with those of 1854 they show an augmentation of L,1,723,976. The receipts during the month of September were L.465,688, or L.40,383 less than in the corresponding month of last year. The salt-tax produced during the nine months of 1855, L.930,891.

The value of exports in 1853 reached L.74,640,000, of which L.54,520,000 represented French produce, and L.20,520,000 was foreign produce re-exported. The imports for home consumption showed an increase of L.4,680,000, and the exports of French produce an increase of L.5,200,000 above 1852.

The following is a brief sketch of the trade of France with other countries.

The corn, the hemp, the flax, the tallow, which form such important articles of export from the north of Europe to England, are comparatively unnecessary to France. Their timber and pitch are imported there, but the quantities required by a people where shipbuilding is so limited are necessarily of little consequence. It would appear, however, that in the progress of the present war against Russia many articles imported from the north of Europe have become more necessary to France, and by a decree published in the *Moniteur* on the 20th October 1855 building timber, wood for cabinet-making of a certain thickness, rough castings, bar and sheet iron, hemp, &c., may be imported for three years free from import duty. Pitch, tar, and tallow, when employed in ship building, may be imported at a duty of 10 per cent. if it can be proved they have been used *bona fide* for the purpose within a year. The further articles of import are iron, copper, lead, salt fish, all likewise on a small scale. The returns from France are no longer in the sugar and coffee, which, before the loss of St Domingo, furnished an annual export to the north of fully two millions sterling. They are limited to wine and brandy, luxuries of which the consumption is confined to a few large towns, such as Petersburg, Hamburg, Lubeck, Stockholm, and Dantzic.

With Germany the exchanges of France are now carried on by steam canal and land carriage, and for lighter articles and *articles de Paris* by railroad and river navigation.

From Holland are imported spirituous liquors, spices, butter, cheese. The returns from France consist chiefly of wine, silks, brandy, and dried fruit. When the Netherlands were subject to France, this intercourse was very active.

Statistics.

From Italy France imports raw silk, corn, rice, olive oil, and fruit, chiefly lemons, oranges, figs, and raisins. The returns, various in kind, but small in quantity, consist of wine, brandy, cattle, woollens, linen, leather, hats, stockings, jewellery, glass, hardware. From the Levant, the imports, though less than formerly, still consist of raw silk, cotton, wool, corn, dried fruits; the exports, manufactured silks, woollens, stockings, and, in a small degree, hardware, paper, liqueurs, linens, lace. With Spain the intercourse is more extensive: the exports from France consist of corn, flour, salt fish, wine, brandy, also woollens, cottons, silks, leather, linen, lace, hats; all articles which have passed through some process of manufacture, and bear testimony to the industry of the French. The Spaniards, on the other hand, true to their character, make no returns except in produce and raw materials, viz. wool, silk, fruit, sweet wines, along with some iron and copper. During the years 1854 and 1855 there have been considerable exportations of Spanish wine into France for the use of the French troops serving in the Crimea. With Portugal the trade of France is not considerable, the staple products, wine and brandy, being the same in both countries.

The intercourse between the French and Americans should be great, but the Americans require long credit, and to give credit exceeds the means of the French. The cotton, tobacco, and rice of the United States are paid partly by wine and brandy, but in a slight degree by manufactures. This branch of trade will increase with the population and wealth of the United States. At present the intercourse with England is more considerable than with almost any other country; but a reduction of the custom-house duties would extend greatly the mutual trade of the two countries. Great Britain would supply France in greater quantities with imports, consisting of cottons, hardware, earthenware, copper, tin, iron, coals, &c.; whilst a corresponding increase would take place in the French exports, of which the staple articles are wine and brandy, the smaller silks, olive oil, fruit, butter, poultry, corn, and butcher meat.

The chief commercial business of Paris is necessarily inland; but it is the centre of exchange transactions for France, foreign as well as inland; as London is for England, and Amsterdam for Holland. Havre de Grace is the channel of the maritime intercourse of the capital, the outlet for its exports, and the medium through which it receives colonial produce, raw materials, and foreign manufactures. Bordeaux is a seaport of great activity, as well for the exportation of wine and brandy, as for the importation of sugar, coffee, and cotton. Marseilles, a larger but a less bustling city, continues the emporium for the trade with Italy and the Levant. Nantes has suffered greatly by the loss of St Domingo, as well as by the abolition of the slave trade, of which it was the centre. It still exports to Martinique and Guadaloupe linen, hardware, printed cottons; and, like Bordeaux, receives in return sugar, coffee, and raw cotton. Rouen, though accessible to vessels of burden, is, like Lyon and Lille, chiefly remarkable for manufactures.

The mercantile marine of France recently presented the following results, which are remarkable while England and America are building vessels of such superior tonnage.

Mercantile Marine—1853.

Tonnage.	Vessels.	Total Tonnage.	Tonnage.	Vessels.	Total Tonnage.
700 to 800	1	717	100 to 200	1,365	197,947

The coasting trade of France employs a number of vessels which in the returns vary from 80,000 to 90,000 entries and departures, with a tonnage of 2,250,000 and 254,150 men; to 2,500,000 tons and 330,000 men.

The circulation of the Bank of France has increased since 1848, first, in consequence of smaller notes being put into circulation (for notes of 100 francs are now current), and, secondly, because of the establishment of branch banks facilitating intercommunication with all the principal cities of the kingdom. The circulation in 1853 and 1854 exceeded 500 millions. But in those years the amount of specie in the bank cellars exceeded the amount of the whole circulation; so that the substitution of paper for gold was not of so much service, or so economical to the country, as it might have been under other circumstances.

Currency.

The currency of France consists chiefly of gold and silver, in which larger payments are effected, and of copper coins for the smaller sums.

It appears that from 1803 to 1814 there were coined, with the effigy of Napoleon, at the different mints, of which there are thirteen in France, in gold to the value of L.22,001,018, and in silver to the value of L.36,992,502. From 1814 to 1828, the amount of the coinage was L.17,081,635 in gold, of twenty and forty franc pieces; and in silver the amount in pieces of five francs down to five sous was L.36,996,560, bearing the effigy of Louis XVIII. and Charles X. On the above data, the amount of circulating specie in the kingdom was estimated, on the 1st of January 1828, at 2,713,731,183 francs, equal in value to L.113,072,132 sterling. The gold and silver currency, prior to the Revolution in 1789, was estimated at L.87,500,000 sterling. We can scarcely, however, draw any positive inference from the quantity of gold and silver coined in France, respecting the amount of the specie actually circulating, as within the last twenty-seven years the exportation of coin has been freely permitted. The coinage of France has accordingly become an article of trade; and bullion and coin have been freely exported or imported, according to the necessities of commerce. For the ten years preceding 1830, the quantity of bullion imported exceeded the quantity exported by L.39,089,667.

The amount of the gold and silver coinage in France for 1853, with the value in francs and in sterling money, was :—

Gold.	Coinage.	Value.	Value Sterling.
20-franc pieces........	15,641,500	312,830,000 fr.	L.12,513,200
10 do. do.	1,763,346	17,633,463	705,336
Total gold......	17,404,846	330,463,463	L.13,218,536
Silver	5,090,236	20,089,778	803,588
Copper	30,869,285	1,974,939	78,976
	53,366,367	352,528,180	L.14,101,120

Bank of France.

This bank, which is the city privileged bank in France, received its charter in 1803 for fifteen years, which was afterwards extended in 1818 to the year 1845. It was again extended in 1840. The law of the 30th June 1840 limited the existence of the bank to the 31st December 1867, reserving to the government the right to cause its privileges to cease on the 31st December 1855. An agreement was entered into between the government and the bank on the 3d March 1852, by which the former agreed to waive its right, in consequence of certain advantages conceded by the bank to the executive government. It is under the direction of a governor, named by the head of the state, whether emperor, king, or president, with a salary of 100,000 francs a-year. It has, besides, two deputy-governors, paid by the bank but appointed by the government, and a general council of fifteen *regents* and three *censeurs*, subdivided into six committees, and assisted by a council of discounts composed of twelve members chosen from among such of the shareholders as are merchants. This bank issues notes of the amount of 10,000, 5000, 1000, 500, 300, 200, and 100 francs. The 200-franc notes were first circulated in 1846, the 100-franc notes in 1848, and the 10,000 and 5000 franc-notes have been issued since 1843, which are payable in specie on demand by the holder. Its capital, which consists of 67,900 shares at 1000 francs, making a total of 67,900,000 francs, is employed in discounting bills of exchange, in making advances of money in government securities, and in deposits of bullion or foreign coin, diamonds, shares in public companies, at the rate of one per cent. per annum.

Not less than the value of 10,000 francs is received as a deposit, and discount for forty-five days is deducted from the amount of the sum advanced; nor, if the deposit be redeemed the next day, is any part of the discount refunded. The paper of the Bank of France chiefly circulates in Paris and the neighbourhood; at a distance from Paris its notes pass at a discount of one-and-a-half per cent., as they are not received in payment of taxes or custom-house duties in seaports; so that remittances to Paris must be made in cash, for which a charge of five per cent. is made at the post-office: the dividend of the bank on each share has been thirty francs half-yearly, or at the rate of six per cent. per annum. A surplus fund, which had accumulated, was, in consequence of the reiterated demands of the shareholders, put in a course of distribution; and in the year 1831 two entire dividends were made of fifteen francs and six francs per share, besides two other payments, under the name of a bonus of reserve, the one amounting to seven francs fifty centimes, and the other to three francs, per share. The balance of the reserved fund amounted in 1830 to 6,974,398 francs, which would give a further bonus of 146 francs 95 centimes on each share; and for the purpose of authorizing the distribution of this sum, a law was passed in December 1831. By this law the bank was bound to hold a third part of its profits in reserve, after paying the regular dividend of six per cent. per annum. The Bank of France has now *comptoirs* or branch banks in from twenty to twenty-five of the principal cities of France. The issue of these branch banks was limited to 350 millions of francs by a decree of 1848. The shares of the bank, which, antecedent to this decree under the government of Louis Philippe, had risen to 3550 francs, became depreciated, and fell to 1250 francs. In January 1852 these *actions* or shares were quoted at 3100 francs. In August 1850 the Bank of France was authorized to resume its payments in specie. A decree of the 13th August 1850 suppressed the *cours forcé* of the notes, and extended the circulation. These two decrees restored confidence, augmented by the weekly publication of the accounts of the establishment.

Crédit Foncier.

The society of the Crédit Foncier de France was authorized by the decrees of the 28th March and the 10th December 1852. Its operations extend over the whole of France, with the exception of six departments. The capital consists of 60,000,000 of francs, and the society cannot lend to any one individual more than a million, nor less than 300 francs.

Crédit Mobilier.

The Societé Générale de Crédit Mobilier, established by a decree of 18th November 1852, is a species of bank, the partners in which have not given their names. Its principal operations consist in purchasing or acquiring shares in public companies, provided they be *en sociétés anonymes*. Secondly, in circulating its own securities for a sum equivalent to the shares or stock purchased. Thirdly, in selling and exchanging all *actions* and *obligations* so acquired. Fourthly, in lending on public securities on the deposit of *actions* and *obligations*, &c., &c.

The capital of the society is fixed at 60,000,000 francs, and it is represented by 120,000 shares of 500 francs each. The society can circulate *its own "obligations" for a sum six times as large as its capital.*

Fairs.

Land carriage in France, or *roulage*, costs only from 2s. to 2s. 6d. per cwt. for a hundred miles; a cheapness which facilitates the transport of merchandise to the various annual fairs which are still held in every great town in the kingdom, exactly as was done by our forefathers a century ago. This periodical routine begins by the *foire de Longchamps*, which is held annually at Paris in spring, and is followed by a long list of provincial fairs, of which the chief are those of Beaucaire in Languedoc, and Guibray in Normandy. The *roulage* of France is now only had recourse to for heavy goods, and in lines of country where there are neither rivers, canals, nor railroads. The law of France has many provisions as to roulage and as to *rouliers*, the drivers or waggoners who conduct merchandise, and generally travel at the rate of from eight to ten leagues a-day.

Colonies.

The colonial possessions of France are quite unsuited to her greatness in other respects. The insurrection engendered by the first Revolution deprived her of the western half of St Domingo, a rich and beautiful territory, containing formerly more negroes, and exporting more produce, than all the British West Indies together. The French government seems to have relinquished the hope of regaining this country, at least by military means, and to limit its ambition to the remaining colonies, Martinique, Guadaloupe, Cayenne, in the West Indies. The first two are, like most of our West India islands, cultivated to a considerable extent, but capable of much improvement. The petty island of Marie Galante is in a similar state; but Cayenne forms a part of a most extensive tract, of which one corner only is as yet rendered productive, and which may eventually become a great settlement; though on the score of health it is as unpromising as the adjacent colonies of Demerara and Surinam. Before the loss of St Domingo the annual import into France amounted to 70,000 hhds. of muscovado or brown sugar, 60,000 hhds. clayed, and nearly 20,000 of fine clayed. Of this very large supply there were exported nearly 40,000 hhds. of brown, and above 60,000 hhds. of clayed, forming, exclusively of any duty, an annual value of between L.2,000,000 and L.3,000,000 sterling, and affording a most acceptable exchange for a number of imported commodities. The sugar thus imported from St Domingo has long been lost to France, no sugar being now exported from that country.

Algiers

Among the colonies of France is Algeria, which the government has retained since its conquest in 1830. Of this dependency Algiers is the capital, the seat of government, of a prefecture, and of a bishop's see since 1838. Algiers also possesses a government printing office, an academy of public instruction, a court of appeal, a tribunal of first instance, a tribunal, and a chamber of commerce. A bank has been recently established. Several newspapers are published at Algiers. The *Moniteur* of Algiers is the official paper. There is also the *Akhbar*, the *Mobacher*, the official journal in Arabic, the *Atlas*, &c.

The population of Algiers, according to the last returns, amounted to 55,682 Europeans, of whom 23,147 were French, and 24,996 natives, of whom 17,858 were Mussulmen, 1380 negroes, and 5758 Jews. A Protestant church was commenced in Algiers in 1843 and finished in 1845. There are at Algiers four large mosques and about thirty lesser ones, two great and twelve lesser synagogues. There are few manufactories in the capital unless of silks, carpetings, woollen tissues, fire-arms, saddlery, jewellery, leather, &c. From the last published official returns there entered Algiers within the year 2279 ships, measuring 209,642 tons; of these 255 were government vessels, 1134 French commercial bottoms, and 120 native; the remaining vessels were under foreign flags. There sailed outward from Algiers, in the last year of which we have any official records, 2297 ships measuring 208,319 tons. Of these 249 were government ships, 1148 French ships, and 117 native. By a decree of the present Emperor of the French, a bourse was created at Algiers on the 16th April 1852. For a more detailed account, see ALGIERS.

Statistics.

In Africa the French possess Goree and some factories near the mouth of the Senegal. In the East they have the Isle of Bourbon, and Pondicherry, Chandernagore, and some smaller factories on the mainland of India; and their vessels are, like the Americans, admitted to trade with Calcutta, Madras, and other British settlements, on payment of moderate dues. The retention of the Mauritius by England, at the peace of 1814, deprived them of the great receptacle for their privateers in the East; and in the continent of North America, they retain nothing since the cession of Louisiana to the United States in 1803. Since 1841, when the sovereign of the island of Mayotte placed himself under the protection of France, this island, situated at the extremity of the Mozambique Channel, is to all intents and purposes a French settlement. Mayotte is capable of feeding a population of 20,000 souls, and of regularly furnishing provisions to a squadron of ships. France also possesses an establishment in Australia, for since the 22d March 1854, Captain Dubouzet has been commandant of the Marchesas and imperial commissary at the Society Islands and New Caledonia. There is also an unimportant French settlement at Madagascar, and an attempt at a penal colony has been made at Guyana, where, to the disgrace of the French government, political prisoners have been mixed with the refuse of the galleys. In the seas of Europe, Corsica is almost the only insular possession of the French. They have no great maritime fortresses, like Gibraltar or Malta, and no dependencies of the nature of the Ionian Islands.

Commerce, &c.

The commerce of France with her colonies is regulated by the same narrow maxims as the other branches of her foreign trade. The colonies and the mother country are mutually bound to trade exclusively with each other. The staple produce of the French West India colonies, as well as the Isle of Bourbon in the East, is sugar; and it appears that the price of this article in the European markets will not repay the expense of its cultivation in those countries. The colonists, therefore, insist that all other sugars shall be excluded by heavy duties from the markets of France; that they shall have the exclusive privilege of supplying these markets; and on a complaint that the duties imposed on foreign sugars were not high enough to give them the monopoly of the home market, an additional duty was, in 1822, on the suggestion of the director-general of the customs, imposed on all foreign sugars. In return, France possesses the exclusive privilege of supplying the colonies with all the manufactures and other European goods which they require. On this principle of mutual monopoly the trade is now conducted. The effect of this system is to levy a tax on the inhabitants of France, in order to indemnify the colonists for the losses which they incur in carrying on an unprofitable trade. They cannot furnish a supply of sugar to France at the ordinary rate of the European market; and the price must therefore be artificially raised in that country, in order to enable them to carry on the cultivation of their estates; whilst, on the other hand, they are not at liberty to buy the goods which they require in the cheapest market, but must take them at whatever price they can be afforded by the mother country.

Another evil of this colonial monopoly is, that the colonies supply more sugar than France can consume. But it cannot be sold in other countries at the price which is paid to the colonies by the mother country; and hence it becomes necessary to find out the means of forcing a sale of the surplus which cannot be consumed at home. A bounty is accordingly granted on all sugar exported from France; and in 1831, whilst the duty on the importation of sugar produced L,1,636,030, there was paid back for bounties L.483,951, which was more than one-fourth of the gross receipts. The loss which France has incurred since the peace of 1814 by this erroneous system is estimated in Bowring and Villiers' Report, at L.40,000,000 sterling; and in return for these great sacrifices, the colonies afford but a limited demand for the manufactures of the mother country; in 1852, it amounted to 23,482,000 kilogrammes; in 1853, to 26,481,000 kilo.; in 1854, to 33,297,000 kilo.

Statistics.

The republican government of 1848 proceeded to greater lengths in granting bounties than either of the governments of the Restoration or the government of Louis Philippe for the *primes* or drawbacks of 1818, 1820, 1823, 1826, 1833, 1836, 1841, and 1845 were increased to 50 per cent. from the 15th June 1848. Restored to their former rate, these drawbacks in the three years antecedent to 1854 rose to a sum varying between 25 and 27 millions of francs.

General Trade of France with its Colonies.

Colonies.	Year.	Importations.	Exportations.
Martinique..................	1853	L.652,441	L.765,577
Guadaloupe	1853	423,655	570,434
Bourbon	1853	851,647	684,946
Senegal	1853	287,206	392,369
Cayenne	1853	56,833	184,044
India	1853	669,723	21,384
Algiers	1853	1,132,304	3,395,966
St Pierre & Miquelon, &c.	1853	617,631	278,637
Isles Mayotte, and Madagascar	1853	8,627	36,584

The trade to Bourbon island, Guyana, Martinique, and Guadaloupe, out and home, employed in 1848, 492 ships; in 1849, 541; 1850, 486; 1851, 602; 1852, 677; 1853, 583. The mean of the first five years 560 vessels.

The trade to Algiers, Senegal, India, Madagascar, out and home, in 1848, 1843 vessels; 1849, 1938; 1850, 1902; 1851, 2194; 1852, 2443; 1853, 2177; mean of the first five years 2064.

Fisheries.

All along the north coast of France, the fisheries consist, as on our side of the Channel, of cod, mackerel, herrings, and pilchards. On the shore of the Atlantic, and still more on that of the Mediterranean, are caught great quantities of sardines, a fish of passage, which appears periodically in shoals, like the herring. The fishery of *sardines* is said to give employment to 3000 seamen, and the sales resulting from the produce amount to between 3,000,000 and 4,000,000 of francs. The tunny, a fish not known in northern latitudes, is found in the Mediterranean in the early part of summer. It varies in weight from ten to twenty-five pounds, and is in like manner caught in shoals.

These home fisheries, little calculated for forming seamen, have been left to their natural progress, whilst repeated attempts have been made by government to extend the fishery in America; a design favoured by the early possession by France of Newfoundland and Canada, as well as by the long peace that followed the treaty of Utrecht. Towards the middle of last century the French fisheries in America employed annually about 5000 seamen; but the unsuccessful contest with England in 1756 reduced them greatly, and deprived them of their principal station, Cape Breton. The peace of 1783 was concluded under better auspices. The islands of St Pierre and Miquelon were ceded to France by the treaty of Versailles, and the rights of fishing and of drying fish from the Cape St John to Cape Ray. In the Gulf of St Lawrence her rights were subsequently recognised, by the treaties of 1802 and 1814, at three leagues distance from the coasts belonging to Great Britain; but within the gulf, at a distance of fifteen leagues from Isle Royale, and thirty leagues from New Brunswick.

For the encouragement of the French fisheries, enormous pecuniary sacrifices have been made. By the law of the 22d July 1851, bounties are granted to the fisheries till 1861, at the rate of 120 francs the ton. A ship of 600 tons thus receives 72,000 francs bounty, which would be 2000 to 3000 francs per man. The only time they were ever in a prosperous state was, not when they were protected by the artificial encouragement of the mother country, but when the French colonists, being in possession of a large tract of the American sea-coast, were in consequence compelled to trust to prudence and economy alone for the success of their adventures. During the session 1833 of the Chamber of Deputies, a committee, appointed to inquire into this subject, made their report, in which they state—

> "That the French fishermen have now to compete with those who are always on the spot; who carry on their fishing concerns in small boats, and at a trifling cost; who pay no charge of outfit; who lose no time in voyages; who employ the cheaper labour of

children, women, and old persons; who have their drying and salting establishments in the neighbourhood; and who can accommodate all their proceedings to the urgency of circumstances." It is to counterbalance these advantages that France has resorted to the system of bounties, which has been carried to a great length in order to force the establishment of a trade in the face of natural obstacles.[1] The result of the investigations of the committee was the recommendation to government to grant such a premium to those who adventured in the fishery as should place them on a level with their more fortunate rivals. In 1816 a bounty was granted of fifty francs per man for the cod-fishery, fifteen francs per man for the herring fishery, and twenty-four francs per cwt. on the introduction of the fish into the colonies. In 1818 these premiums were raised by royal ordonnances to forty francs per cwt., which is more than 100 per cent. on the value; and the market price of the fish became in consequence a nett profit to the adventurer. This premium was reduced in 1822 to thirty francs per cwt. But a new law was passed in 1832, which was valid till 1837, and which allowed a premium of fifty francs for every seaman engaged in the cod-fishery of St Pierre and Miquelon; thirty francs for each engaged in the fisheries of the Great Bank of Newfoundland, or Iceland; fifteen francs if on the Dogger Bank; and fifty francs in every case if the fish are dried at St Pierre or Miquelon. An additional premium was allowed of twenty-four francs per metrical quintal or 2 cwts. on cod-fish shipped from France to the French colonies, thirty francs if shipped direct from the fisheries, twelve francs per quintal if shipped to other ports from France, and ten if direct from the fisheries; also twenty francs per quintal as a premium on cod-roes. The effect of these bounties was and is to place the adventurer in the French fisheries beyond all risk of loss. In many cases they were equal to the whole expense of the outfit, the voyage, and the return; and, though no cargo is brought home, no loss can be incurred. The whole expense and hazard of the trade is thus borne by the public. Two-thirds of the products of the French fisheries are consumed in France, the other third is exported to the French colonies or to foreign countries. It is to this last third that the varying scale of bounties is applicable, and the sums paid in this way it is calculated yearly take from France a sum varying from 3,000,000 to 3,500,000 francs.

The bounties paid for the cod-fisheries in 1852 absorbed between 6,000,000 and 7,000,000 of francs, which was more than double the sum paid on the average of the five years between 1820 and 1830.

The vessels equipped for the fisheries of Newfoundland, St Pierre, Miquelon, &c., proceed from the ports of St Malo, St Brieuc, and Granville. The vessels proceeding to Iceland sail from Dunkirk.

The French fish are of very inferior quality to those caught by the Americans, the latter selling at forty-seven francs thirty-five centimes per quintal, whilst the French cod-fish only brought twenty-six francs ninety-five centimes.[2] With all this expense, however, the French fisheries are not adequate to the supply of the colonies, which receive considerable quantities of fish from foreigners, as will be seen from the following table.

Fishery and Export of Cod from 1848 *to* 1853.

Years.	Ships.	Men.	Expenses of Shipping.	Exportation from allports. cwts.	Total expenses.
1848	354	11,142	L.13,931	311,733	L.112,340
1849	324	10,606	20,000	338,733	123,204
1850	363	11,710	22,202	306,030	117,482
1851	396	12,649	24,140	408,351	154,982
1852	419	13,648	25,994	400,154	145,174
1853	421	13,588	25,347	372,715	133,190

Statement of the whale-fishery from the French ports—Havre, 5 vessels, of 2045 tons and 127 men; return of product, 22,142 cwt. of oil of the whale; 30 cwt. of the cachalot; 1608 cwt. of whalebone.

French Cod-Fishery Importations and Exportations—fresh, dried, oil, &c.; and Importations of Whale-Fishery.

Years.	Cod-Fishery.		Whale-Fishery. Imported.
	Imported.	Exported.	
	Cwts.	Cwts.	Cwts.
1848	412,431	82,964	10,711
1849	388,374	88,251	19,047
1850	376,132	62,070	20,157
1851	403,377	85,410	17,477
1852	378,862	54,400	3,889
1853	345,541	55,307	12,081

The mean of the first five years is above 391,915 quintals.

Vessels of France employed in the fisheries generally—1848, 849; 1849, 685; 1850, 838; 1851, 925; 1852, 959; 1853, 943. The mean of five years is 851 vessels.

The total amount of cod-fish exported in 1853 from all the ports of France amounted to 1,537,971 kilogrammes, or 55,307 quintals.

Whale-fishery. The whale-fishery was established in France in 1784, by means of encouragements held out by Louis XVI., who ordered that no duty should be collected on the articles exported, and that the produce of the fisheries should pay no import duty.

He guaranteed the adventurers against loss, and ultimately paid, in addition to L.12,500, which he advanced without interest, an additional sum of L.6695, being the balance of loss on seventeen voyages. Notwithstanding these encouragements, the whole project was abandoned in 1787. In 1816 the offer of bounties attracted new adventurers into this branch of trade. The premium offered by the government was fifty francs (L.2) per man, and two-thirds of the crews were allowed to be foreigners. In 1819 forty francs were allowed to foreign vessels having a crew half French, fifty francs when the captain and one-third of the crew were French; the premium to be doubled if the vessel passed Cape Horn. In 1829 a new ordonnance granted ninety francs per ton on vessels wholly equipped by Frenchmen, forty francs when only two-thirds were Frenchmen, and thirty francs if the captain was a foreigner. The premium was doubled if the vessel passed Cape Horn. A supplementary premium was allowed to vessels fishing to the south-east of the Cape of Good Hope, and the double premium was given to all vessels fishing at a higher northern latitude than sixty degrees; and as the fishing is seldom or never prosecuted at a lower latitude, this premium of 180 francs per ton (L.7, 4s.) was invariably paid. The law of 1832, which regulates the whale-fishery of France, established a bounty of seventy francs per ton from March 1832 to March 1833, if the whole crew were French; the bounty to be diminished four francs yearly till it reached fifty-four francs. If one-third of the crew be foreigners, the bounty to be forty-eight francs per ton, to diminish two francs yearly till it reached forty francs per ton. A supplementary bounty to be given of fifty francs per ton if the crew be French, decreasing three francs per annum per ton; and twenty-four francs if one-third be foreigners, decreasing one franc per annum, to be paid to vessels doubling Cape Horn, or reaching sixty-two degrees of south latitude, if returning with less than half a cargo, or after an absence of sixteen months; five hundred tons to be the minimum for a single whaler.

With these extraordinary encouragements, capital was attracted to this new line of industry; and in 1831 three vessels cleared out for the Greenland whale-fishery, and thirteen for the South Sea fishery, which employed 6412 tons of shipping, and were manned by 551 men. Notwithstanding all the bounties given to the whale-fishery, France has very few vessels engaged in it. There were only seventeen ships in the trade in 1849, and seven only re-entered French ports. There were but five vessels left Havre in 1853, of a tonnage of 2045 tons, and with a crew of 127 men. The return of the product was 112,485

---

[1] There are two different bounties applicable to the cod-fishery, one calculated on the scale of the number of the crew, the other on the product of the fishery. The second is given on the dried cod-fish sent to the foreign markets, and this bounty on exportation varies according to the places of destination.

[2] Anterior to 1832, so bad was the French cod-fish exported to the West Indies (with a view merely to receive the bounty on exportation), that it could only be used as manure; of three cargoes of French cod-fish exported to Oporto in 1849, two were so bad that they were thrown overboard.

Statistics.

kilogrammes of the whale, 1589 of the cachalot, and 81,710 kilogrammes of whalebone.

It was estimated by the minister of commerce, in his report on this subject to the Chamber of Deputies more than twenty years ago, that the 550 seamen employed in the whale-fishery do not cost the state less than 1,000,000 francs, at the rate of L.72, 12s. per man, or L.6 a month. The wages granted by the budget to seamen employed in ships of war amounted to L.1 per month; so that the allowance to the seamen employed in the Greenland fishery is six times the ordinary allowance of seamen in the public service. It is remarkable that France was granting these extravagant allowances for the encouragement of the whale-fishery exactly at the time that Great Britain was withdrawing the bounties by which she had formerly endeavoured to promote this branch of trade as a nursery for seamen. Yet in 1830 the number of vessels that cleared out for the fishery in England was 123, consisting of 40,166 tons, navigated by 5044 seamen; being thus about eight times the quantity of tonnage employed by France. The government of Louis Philippe, alarmed at the large outlay in bounty, endeavoured to lessen it, and to render it transitory and temporary only. M. d'Argont, the minister of commerce, insisted that these bounties exhausted the resources of the state, and decreasing bounties were after a period adopted, but M. Cunin Gridaine, who was minister of commerce, relapsed into the old error by introducing supplemental bounties. The provisional government of 1848, by one decree augmented the bounties, and by a second extended the term of the law to 31st December 1851. On the 22d July 1851, the National Assembly voted for the continuance of the bounties to 1861.

Shipping.

France seems destined, by the natural advantages which she possesses, to become a maritime power of the first rank. Her sea-coast exceeds in extent that of any other continental state. On the Atlantic she has 130 leagues of coast, 150 on the Channel, and ninety on the Mediterranean; whilst her position between northern and southern Europe, and her numerous ports and navigable rivers, are eminently favourable to the extension of her navigation. But in this, as in all other branches of the French trade, the prejudicial effects of the restrictive system have been abundantly manifest. France, in forcing a trade with her colonies, containing less than half a million of inhabitants, has sacrificed her trade with other tropical countries and their numerous population, to the great injury of her shipping interest.

A great increase has taken place in the tonnage employed in the coasting trade of France, a fact which affords clear and convincing evidence of the extending resources of the country, which would have equally occasioned an increase in the shipping employed in the foreign as well as the domestic trade, if this important branch of industry had not been stunted in its natural growth by the monopolizing system. The navigation of France no doubt suffered grievously during the last war, under the maritime hostility of Great Britain. But in the course of nearly twenty years it would have recovered from this state of depression, if the natural energies of the country had been allowed free scope in this line of industry.

Butcher's meat in Paris.

The Revolution of 1830 did not alter the system prevailing antecedently with respect to the trade in butcher's meat, but modified it. The same may be said of the Revolution of 1848. It did not change the system but modified under certain heads the practice of the trade. The *droits d'octroi et de caisse de Poissy* were at first suppressed, then re-established, but with a radical change in this respect, that the duty was levied by the *weight* of the cattle and not at so much per head as before. This alteration had long been ineffectually demanded by the agricultural breeders. Butchers from the interior of France were also to provide stock and meat for the Paris market as well as their brethren of the capital. These regulations and modifications satisfied neither agriculturists nor butchers. In the month of January 1851, the National Assembly directed an inquiry into the production and consumption of butcher's meat. The commission charged with this inquiry seriously engaged in it, but the events of the 2d December 1851 prevented it from finishing its task. From the portion of the report, however, that has been printed, we know that it was the opinion of the committee that there should be liberty of commerce in meat, and that the local authorities should, under no pretext whatsoever, be allowed to interfere with this cardinal principle. The committee considered meat, like spice, silk, or cloth, a mercantile commodity, and were of opinion that the police should only interfere as to frauds in reference to the quantity or quality, or as to the wholesomeness of the victual as an article of food. This was only returning to the principle professed in the laws of the 14th and 17th June 1791, and the 1st Brumaire An. VII. On the question of the *octroi* they were of opinion that it interfered with the price and consumption of food, and that it should be abolished from the 1st January 1860. Since this report was published the price of butcher's meat has increased, and the supply has diminished at Poissy, the great market which supplies Paris. In consequence of this, recourse was had to an expedient which sound political science has proved to be utterly ineffectual. An ordonnance appeared in the *Moniteur* of the 11th and 12th October 1855, of which the following is the substance:—

> On and after the 16th of the present month, butcher's meat shall be sold at prices taxed by the authorities.
>
> The price shall be fixed every fortnight for every kind of meat, according to the returns made at the Caisse de Poissy, and to the weight of meat ascertained to have been sent from the public slaughter-houses of Paris during the preceding fortnight.
>
> (Then follow instructions regulating the manner in which the different kinds of meat are to be divided and arranged as to prices.)
>
> In the shops established in the markets, meat shall be sold at 10 c. at least per kilogramme (about a halfpenny per lb.) below the fixed price.

This decree, which violates every sound principle of political economy, appears to have been well received by the poorer classes of the population, who had long complained of the dearness of meat, and of the exorbitant profits of the butchers. But the way to reduce the profits of the butcher is to destroy the monopoly, and to render trade in meat free.

VIII. RELIGIOUS AND CHARITABLE ESTABLISHMENTS.

The condition of the church and clergy forms a most important feature in the history and present situation of France. In former times, the Gallican church, without desiring a separation from the holy see, had often advanced a claim to independence, and maintained long and animated discussions, or rather controversies, familiar to those readers of the French annals who have attended to the history of the Jansenists and Molinists. The result of these, and of the general progress of knowledge in France, was an exemption from a part at least of the interference in ecclesiastical affairs, exercised so despotically by the court of Rome in Spain, in Portugal, in Italy, and now in Austria. As to pecuniary means, though the income of the lower ranks of the clergy was extremely small, the church of France was on the whole richly endowed; antecedently to the first French Revolution the rent of land and houses appropriated to abbeys, priories, bishoprics, archbishoprics, and benefices of every description, being computed at five millions sterling, exclusive of the tithes levied, with more or less strictness, throughout the whole kingdom. As a political body, the French clergy were differently situated from the English, having no voice in legislating, but aiming at, and frequently attaining, the highest offices in the executive government.

In 1789 a number of the clergy, both in the upper and lower ranks, participated in the general wish for a political reform, and evinced that disposition by their readiness in coalescing with the *tiers état*, at a time when the majority of the noblesse refused to do so, until compelled by the call of the people, and the positive order of the court. In the highly interesting discussions that ensued during the years

1789 and 1790, some of the leading orators were Roman Catholic clergymen, nor did they in general take the alarm, until the menacing aspect given to public affairs by the too rapid progress of the Revolution. The National Assembly stripped the church of her lands, and declared them the property of the public, providing, indeed, for the income of the clergy, but making the payment of it dependent on government. All this might have passed and been forgiven in the ardent hopes of national benefit from the Revolution; but the assembly did not stop here. Considering both the court of Rome and the court of France inveterately hostile to the Revolution, they determined to detach the clergy from both, and sought to compel their adherence, by imposing on them an oath of fidelity to the new constitution, on pain of forfeiture of their livings. The sincerity of the clerical body was now put to the test, and a striking proof was given of their being actuated by that conscientious feeling for which the public in Protestant countries are so little disposed to give them credit. In every rank, whether prelates, vicars, or the humble curates, the majority preferred the hazard of losing their livelihood to taking an oath at variance with their conscience. The violent party continued to triumph at Paris, and the nonconforming clergy had no alternative but to fly their country. Hence the crowds of emigrants who, in 1791 and 1792, sought refuge in Italy, Germany, and, above all, in England. Those who remained in France were exposed to all the atrocities of the Jacobins. Hundreds of them were sacrificed in the massacres of September 1792, and hundreds more were brought to the guillotine in the dreadful years 1793 and 1794. With the fall of Robespierre (July 1794) the executions ceased; but a tone of hostility to the church was still kept up, and accounted an indispensable part of the policy of the revolutionary government. The only class allowed to remain in quiet were the *curés*, whose humble station and scattered position created no political alarm. It was not till the established sway of Bonaparte (in 1801) that circumstances admitted of cooler calculation, and enabled that skilful ruler to seek in a hierarchy a prop to his own power, and an engine of opposition to the liberal party, which still hoped to secure to France advantages from the Revolution. With this view he affected great respect for the Roman Catholic Church, concluded a concordat with the pope, and made a pecuniary provision for a specified number of sees. His next step was to frame and circulate throughout all France a catechism, calculated to impress the rising generation with a profound veneration for a sovereign who had been "anointed by the pope, and received his mission from the Almighty." The power of Bonaparte received in this manner a most substantial support, and would have taken deep root with the lower orders, had he not counteracted it by his subsequent quarrel with the pope, which assumed an angry aspect in 1809, and became more and more aggravated during the remainder of his reign.

On the restoration of the Bourbons in 1814, the Catholic clergy hailed the change with enthusiasm; but the public, at least the great majority of the middling classes, soon showed a marked distinction between their cause and that of the king. The conduct of Louis in regard to the clergy was marked by moderation and judgment. He sought to revive similar impressions among his subjects, to enforce the observance of the Lord's day, and to relieve from indigence the country curates. But he placed no clergymen in political situations, nor attempted to give the bishops or archbishops seats in the House of Peers.

Concordat.

A concordat or compact between the pope and the king is a transaction of high importance in a Catholic country, where the public are impressed with the belief, that in all that relates to religion, reference ought to be had to the court of Rome, and that their temporal sovereign possesses authority in such affairs only as far as it is delegated by the holy father. The object of a co̅ncordat is to define the respective powers of the pope and the king. In France the aim of the executive government has long been to secure the patronage of the church, and to stipulate that no bulls, briefs, decrees, or other acts of a nature to agitate the public mind, should be promulgated without the royal or imperial sanction, or the sanction of the head of the executive power. Three centuries ago, when the alarm of the Reformation, and some urgent political considerations, made it of importance to the court of Rome to attach to its cause the reigning sovereign of France, there was passed between Leo X. and Francis I. a concordat, declaring that the power of nominating the archbishops and bishops of France resided in the crown, the sanction of the pope being required only for their inauguration (*institution canonique*). This compact was considered a kind of charter or standard document in the long discussions which afterwards ensued about the independence of the Gallican church, until the whole sunk into insignificance before the storm of the Revolution. During the ferment of that convulsion, the Jacobins, and even the Directory, made no proposition for accommodation with the holy see, and bade, or affected to bid, it defiance. Bonaparte, more politic, concluded a concordat, which, though it reinstated only 50 of the 130 secs existing before the Revolution, stamped him in some measure a restorer of the church. That he did not afterwards augment their number, is to be accounted for solely by a dread of alarming the revolutionists. The Bourbons, on their restoration, appear to have felt all the delicacy of such a measure; and there appears no ground for believing that they intended to restore the lands, the tithes, or temporal influence of the clergy. Negotiations for a concordat were early begun with the court of Rome, but its conclusion was delayed till 1817; and the interest with which it was received in France can be comprehended only by persons resident among a people still agitated by political division, and dreading the influence of the clergy as an engine for the revival of all past abuses. From this, and from differences with the court of Rome that are foreign to our subject, the execution of the new concordat was very tardy.

The prelates of the church of France are as follows:—Cardinals, at present six in number, with an annual income of about L.1000; 15 archbishops, average income about L.600, except the archbishop of Paris and the cardinals being archbishops; 65 bishops, average income about L.400.

The next in rank are the vicars-general, to the number of more than a hundred; and the chanoines or canons, who also exceed a hundred; after which come the *curés* or parish priests, in number nearly 3300, and divided into three classes (first, second, and third), with incomes of only L.40, L.50, or L.60, but with certain emoluments from surplus fees, which vary according to the population of their respective districts. Lastly come the *desservants*, or acting curates, of whom there is one in almost every country *commune* or parish in the kingdom, amounting in all to 26,000, but with incomes of only between L.20 and L.30 a-year; a pittance equal to about L.40 in England, but still too small to provide for even the limited wants of a state of celibacy. There are also a number of *succursales*, or chapels, appended to large parishes; but of these a considerable number (at present about 2000) are vacant from want of funds, bad repairs of the building, and other causes. These various appointments are all paid out of the public treasury. The expense of the Catholic Church is about L.1,100,000 sterling a-year; but as there are other heads of disbursement, particularly salaries to Protestant ministers, the total ecclesiastical charge is about L.1,300,000.

The nomination of all clergymen, whether Catholic or Protestant, under the Bourbons, was vested in the crown. As to political feeling, the Roman Catholic clergy are generally hostile to the interests produced by the Revolution; but when the republic was in the ascendant they busily planted trees of liberty. In fact they cling to anything established, or that promises stability.

Convents.

Female convents have all along existed in France, with the exception of a few years of the worst part of the Revolution, when their inmates were obliged to forsake their establishments, and to seek an abode with their relations. They are now (1855) very numerous in Paris and throughout France. The most famous and *fashionable*

Statistics.

convent under the Restoration and under Louis Philippe still exists—the Convent de l'Abbaye au Bois. Monasteries are not now very numerous, and no idea is entertained of re-establishing the abbeys, priories, and other endowed establishments; but since the establishment of the empire the power of the clergy has increased, and Jesuits are again openly conducting educational establishments, and preaching in the pulpits of Paris and the great towns.

What, it may be asked, have been the effects of the first Revolution on the state of religion in France? There can be no question, that within the three years between 1852 and 1855 there has been an evident reaction, and in some sort a revival of the religious sentiment among all classes of Frenchmen; the Romish churches and chapels are better attended by the younger and middle-aged men, and are crowded by women of all ages. The first Revolution undoubtedly has subverted the power of the Church, and, what is much more serious, the belief of Christianity in the minds of the young and the middle-aged of the male part of the population; but with the elders of that sex, and with almost all females, the Roman Catholic creed preserves undiminished sway—a sway which extends much farther than can readily be conceived by Protestants. The extent of this influence is owing to various causes; in part to commendable conduct in the clergy, who in general act the part of careful pastors, and attentive visitors in sickness or distress; but in part also to that blind credulity with which the tenets of the church are received both by the hearers and their spiritual guides, whose education has by no means kept pace with the general progress of knowledge; for it does not embrace the philosophical course of the universities of France, but is conducted in separate seminaries, and upon a much more confined plan.

Protestants.

The Protestants in France amount to above 2,000,000, and are most numerous in the south, particularly at Nimes and its vicinity. The Bourbon government received with attention the applications of the Protestants, whether for increase of pastors or repair of churches. They form an industrious and valuable portion of the population; but they are animated by a strong *esprit de secte;* and during the reigns of Louis XVIII. and Charles X. they evinced considerable distrust of the reinstated government. The Lutherans in France have 387 pastors, the reformed religion (of the Augsburg confession) 387, making a total of 775 pastors.

Hospitals.

The hospitals of France are numerous, and derive their revenues from three sources, namely:—

	Francs.
Permanent revenues............	24,453,654·90
Casual sources	16,164,117·36
Sums reimbursed (it is presumed by the state)......	13,498,888·42
	54,116,660·68

The value of the property from which the permanent revenues are derived is about 500 millions of francs. The necessary deductions for repairs and management render the clear sum available under this head 11,291,878·56 francs. The sources styled casual or accidental are derived from sums voluntarily granted by the communes to the hospitals within their boundaries out of their revenues. Before the Revolution, or in 1780, there were only 870 hospitals; there are now 1270. The revenue now, 54,000,000 francs, was then only 20,000,000 francs. At the first period only 110,000 indigent sufferers were relieved, now 126,500. The rate of mortality was nearly the same in 1847 as in 1780, notwithstanding the great ameliorations introduced in all such establishments.

The poor.

The poor in France are reckoned as 1 in 8 of the population. The poor are relieved by what are called the *bureaux de bienfaisance,* which number in all 9336, and possess a revenue of 17,381,267 francs, arising from various sources, such as *monts de piété*, a tax on the theatres, confiscations, legacies, rentes, casual receipts, &c. Of the above sum 683,346 francs are expended in medicines, above 8,000,000 in corn, and above 2,300,000 in cash relief; a fifth part of the total revenue is defrayed in its management. It would appear the poor are but insufficiently succoured. The differences in the numbers of indigent in different parts of the empire are remarkable. In the north the indigent are as 1 to 9, the mendicants as 1 to 62; in the east as 1 to 14, and 1 to 181; in the south as 1 to 18, and 1 to 130; and in the west as 1 to 11, and 1 to 106. In Paris there is one indigent to 12 inhabitants, and 1 mendicant to 397; in Lyon 1 to 10, and 1 to 532; in Marseilles 1 to 7, and 1 to 1429; in Bordeaux 1 to 7, no mendicants; in Rouen 1 to 31, no mendicants; in Toulouse 1 to 33, and 1 in 310; in Lille 1 in 3 are paupers, and 1 in 307 mendicants. The mean relief rendered by the *bureaux de bienfaisance* is 12 francs 70 centimes per head.

Statistics.

Charitable establishments.

Before the Revolution the poor in France, as in Italy and other Catholic countries, were supported chiefly by the abbeys, priories, or other beneficed establishments. On the absorption of these sources of income by the first revolutionary government, a provision for the poor became a subject of legislative inquiry; and, after long investigation, it was determined to avoid a poor-rate on the English plan, but to provide for the aged and helpless an annual fund to the proposed amount of L.2,000,000 sterling. Several years elapsed before this was acted on, and the fund eventually provided consisted of a revival of part of the old *octrois*, or dues levied on wine, cider, spirits, and other articles of consumption, on their entrance into towns; a tax from which the Revolution had relieved the public, and which was now disguised under the specious name of *octroi de bienfaisance.* These dues, however, were soon extended and applied to the general expenditure of the government, after retaining a portion, which at present constitutes the only regular fund for the poor. Further sums are collected by subscription in the depth of winter, or on the occurrence of extraordinary distress. From the public treasury, likewise, there are made occasional issues, in a season of hardship, on the application of the mayors or local magistrates. There are at Paris a number of hospitals, of which by far the largest is the Hôtel Dieu. In the provincial cities there are in general two hospitals for the poor—one for the sick, the other for the aged; besides other charitable institutions.

The money advanced for the succour of mendicity in France varies according to circumstances, such as the customs and resources of the localities. In each commune or parish there exists a committee composed of the mayor, the parish priest, rector, or curate, the Protestant minister, if there be one, and two or three of the principal inhabitants. This committee procures exact information upon the wants and resources of each family, and provides the quantity of head-meat and firewood necessary. A species of voluntary subscription is raised the more easily, as it is levied in kind. The farmer gives bread or wood, the butcher meat, the physician his attendance, the apothecary his drugs. A strict discipline is preserved in the division of the alms, and in fixing the preliminaries and conditions of good conduct. In France the proportion of persons who are succoured by eleemosynary aid is 1 in 10 in the great towns and 1 in 15 in the country. In France a pauper is maintained all the year at L.1 a-head, whereas in England the cost is L.4.

IX. ESTABLISHMENTS FOR EDUCATION.

Educational establishments.

The organization or framework of the system of public instruction in France is one of the happiest applications which has yet been made of the principle of centralization. It is due to the genius of Napoleon. In 1808 he promulgated his decree for establishing the University of France, the provisions of which, being full of the wisdom and foresight so characteristic of his *civil* acts, have engrafted themselves on the institutions of the country, and, with a few slight modifications suggested by experience or by the course of events, are now in full operation, and producing the happiest effects. By this decree the establishments for education throughout France, whether endowed or not, from the village school, through all the gradations of grammar schools, academies, and colleges, up to the faculties and universities, were comprehended under one great central administration, called *l'Université Impériale de*

France. The term *University,* therefore, in the sense first introduced by Napoleon, and now naturalized and generally adopted in France, does not describe, as in Britain and elsewhere, an institution for liberal education, but a branch of the administration or government of the state. Napoleon applied his system of centralization to the university as well as to the government and army. The university has, nevertheless, so much of the nature of a corporate body, that it possesses large disposable funds of its own, consisting partly of real property, partly of pecuniary endowment secured on the public revenue, and partly of the produce of a tax levied on every institution for educating the children of the wealthier classes, which is called *retribution universitaire.* All professors, public teachers, and schoolmasters are necessarily members of this vast body, called the University, the control and direction of which rested under the government of the Restoration.

Administrative Body of the University.

1. The grand master, who was at the restoration also minister of public instruction, with a seat in the cabinet. The grand master, under the kingly government, appointed all the officers of university administration, and filled up all the vacancies in colleges and schools, only, however, upon the recommendation of the inferior local authorities, and after rigorous examinations and comparative trials by them.

2. The second university authority under the kingly government was the royal council of public instruction, composed of ten members, selected from the names most eminent in the various branches of science and literature. They held their sittings in Paris, and were generally distinguished members of the Institute. Their province was to suggest and sanction improvements in the method of teaching; to direct and superintend the compilation of books to put into the hands of youth, and to see that they be adopted in schools and colleges; to judge and remove incompetent teachers, upon the reports of general inspectors; in short, to watch over the concerns and interests of public instruction in all its branches.

3. The university, or, in other words, the whole territory of France, as far as regards the purposes of education, was, under Louis Philippe, divided into *twenty-seven academies,* each comprehending three or more departments; for the term *academy,* like *university* itself, no longer designates a local institution for the training of youth, but a certain territorial extent of educational jurisdiction. In the central town of each academy resided a rector, whose business it was to superintend all the schools, colleges, and faculties within the departments forming his district, to promote their moral and intellectual improvement, to collect the reports of the inspectors employed to visit and examine all places of education under his jurisdiction, to transmit the result to the central administration at Paris, and to serve as the organ of communication with the minister of public instruction. He was assisted and controlled in the exercise of his functions by an academical council of ten, who were partly official persons connected with the university, with the department, and with the municipality, and partly respectable inhabitants of the town, the seat of the academy.

4. Attached to the *conseil royal* were ten inspectors-general of the university, France being divided into ten districts, each visited once a-year by a different inspector, for the purpose of making a survey of the principal establishments, controlling their administration, and reporting to the minister of public instruction.

Besides these inspectors, or agents of the central administration, each rector has, acting under him, two or more *inspecteurs d'academie,* to examine more minutely every primary school or college within the limits of his jurisdiction, and report to him on the general condition of the establishments, on the progress of the pupils, and on the conduct and character of the teachers.

With regard to the constituent parts of the great *corps enseignant,* beginning with the highest, there are,

1. *Les facultés.* The faculties under the imperial system are five; the sciences mathematical and physical, letters, law, medicine, and theology; and all these faculties, with their complement of professors, a dean at the head of each, and an attendance of students more or less numerous, are established in eight towns, namely, Paris, Caen, Toulouse, Strasburg, Dijon, Poictiers, Rennes, and Metz.

It is by the faculties alone that degrees can be conferred, and these degrees are of three kinds: Bachelor's (*le baccalauréat*), which cannot be obtained before sixteen years of age; licentiate's (*la licence*), which presupposes the former, and at least one additional year of age and study; and doctor's degree (*le doctorat*), granted to licentiates when still further advanced in age and acquirements.

2. Subordinate to the faculties, and intended to be a preparation for them, are the colleges; institutions which resemble a good deal the schools of Eton, Harrow, Westminster, &c. The French *collèges* are either royal or communal. Of the former there are at present 39, of the latter 320. Of the 320, by far the greater number are in a very imperfect and inefficient state. The College Royal in the time of Louis Philippe was under the special management of the government. Its directors and professors were paid out of the funds of the nation. The whole was conducted at the charge of the state, and the course of instruction was higher than in the communal colleges. The professors at the college communal are paid out of the funds of the commune.

3. The third and lowest stage of national instruction is that of the *écoles primaires,* corresponding to our parochial and village schools. The law of the 28th of June 1833 new-modelled and added greatly both to the number and value of the *écoles primaires.* It ordains that there shall be a school in every one of the 37,187 *communes* or parishes into which France is divided.

This law provides also for a somewhat fuller and more comprehensive education of the children of the middle class and wealthy burghers in large towns, by ordaining that in every commune which contains above 6000 souls (the number of these in France is 273) there shall be en *école primaire supérieure,* corresponding to and borrowed from the Burger or Mittel-schule of Germany, in which a considerable extension is given to the list of subjects taught in the primary schools. It is also provided that departments may unite themselves to neighbouring departments with a view to have *écoles primaires.* By the law of the legislative assembly, 15th March 1850, there are to be two species of primary schools—the schools founded or sustained by the communes and the departments of the state, which take the name of *écoles publiques;* and the schools founded by private individuals or associations, which take the name of *écoles libres.* The inspection of primary teaching is confided in each arrondissement to an inspector named by the Minister (after having taken the opinion of the Academic Council), and to the cantonal delegates, the mayor, the parish priest, the pastor, or the delegate of the Israclite consistory.

Primary instruction is gratuitously given to children whose parents are not able to pay for it. In order to exercise the profession of *instituteur primaire,* in public or free schools, the teacher must be a Frenchman of the age of twenty-five, and possess a certificate or brevet of capacity, but it may be dispensed with in cases in which the academic council certifies that the individual has during three years taught, in public or free schools, the subjects which form the basis of primary instruction; likewise where the candidates have the diploma of bachelor, or a certificate stating that the bearer has been admitted into one of the special schools of the government. A clergyman, too, of any of the religions recognised by the state, who has not been revoked or interdicted, may be an *instituteur primaire.*

Instituteurs communaux are named by the municipal council of each commune. Every commune is bound to maintain one or more primary schools. Every commune of 800 souls is bound, if its resources permit, to have a school for girls. The academic council also can compel communes of a less population, if they have the means, to maintain a girls' school. All communal schools or girls' free schools kept by lay teachers or by religious associations, cloistered or uncloistered, in so far as regards teaching, are submitted to the inspection and surveillance of the authorities instituted by the law of the 15th March 1850.

The educational system of France may be considered as now happily established, and rendered permanent and efficient, by two other parts of the system. One of these is the *école normale,* established at Paris by Napoleon in 1808, for the purpose of maintaining 300 pupils, and training them not only to considerable acquirements in literature and science, but to the art of communicating their knowledge to others in an attractive and interesting form, and thus to become able regents in the *collèges* and professors in the faculties. None are admitted into this institution who are under the age of seventeen complete, and who have not distinguished themselves in the previous stages of their education. The pupils are divided into two sections, that of the sciences and that of letters, and remain three years in the one or the other. The first two years are employed in confirming and extending their acquirements by a rigorous and effectual discipline under the best professors and teachers that Paris can afford. During the last year they are regarded as future teachers, and trained particularly, both by theory and practice, to the art of communicating instruction. The other security is an extension and application of this noble conception of Napoleon, so as to embrace a preparatory course of discipline for the teachers of the primary schools. This idea, though originated and even acted upon long before the revolution of 1830, never was followed out with energy and effect till after that event; and even so late as 1828 there existed only three *écoles normales primaires,* as these seminaries for schoolmasters are called.

The Institute of France is divided into five academies, viz., the French Academy, the *Académie des Inscriptions et Belles Lettres*, the *Académie des Sciences*, the *Académie Royale des Beaux Arts*, and the *Académie des Sciences Morales et Politiques*.

The *Académie de Médicine* now replaces the Royal Society of Medicine and the Academy of Surgery.

X. ESTABLISHMENTS FOR THE PURPOSES OF WAR.

Army.

The French army first assumed a regular form under Henri IV.; but its peace establishment, including both horse and foot, did not then exceed 10,000 men, whilst the whole charge for the war department, including ordnance and half pay, was L.500,000. In 1610 Henri carried his army to a war establishment of 40,000 men. In 1640, under the able administration of Richelieu, France took an active part in the war of Germany, carrying her force at one time to 100,000 men, and her expenditure to the then unexampled sum of L.4,000,000 sterling in one year. In 1659, Louis XIV., already full of ambitious projects, kept up a peace establishment of 70,000 men; and the war of 1672 having brought Germany, Holland, and Spain into the field against France, the force of the latter country was carried to the number of 160,000 men. From 1679 to 1688 there was peace; but Louis passed the interval in preparing for war; and the introduction of the funding system now enabled France, England, and Holland, to surpass all their former exertions. The contest begun in 1688 required on the part of France a force of between 200,000 and 300,000 men. The peace of Utrecht gave a long repose to exhausted France, and the war of 1741 did not, until conducted in its advanced stage by Marshal Saxe, call forth a military force equal to that of Louis XIV. In the war of 1756 the French army was less numerous, and far less ably commanded. During the continental peace of thirty years (from 1762 to 1792) its establishment was kept, with little fluctuation, at 100,000 men.

The war of the Revolution began with a force on the part of France[1] of only 140,000 men; but this was speedily augmented by the compulsory levies of February 1793, and by the still more comprehensive operation of the requisition in September. It was Carnot, the author of the *Eloge de Vauban* and *l'Essai sur les Machines*, who organized the camp of Châlons, and who at the end of 1793 was enabled, by his indomitable energy, industry, and perseverance, working sixteen hours out of the twenty-four, to oppose to the coalesced enemies of France no less than fourteen different armies.[2] Carnot's was the head and hand which alone directed the war office, and which traced the plans of the different campaigns. During his ministry the finest campaigns of Napoleon and Moreau were organized. It was he who conferred with the generals, and who, without the aid of a secretary, corresponded with the fourteen armies. The republican spirit was now at its height; and the unlimited issue of assignats led to the maintenance of a force hitherto unexampled in the annals of any country, ancient or modern. In 1794, the Frenchmen in *actual service* in the Netherlands, on the Rhine, in Piedmont, the Pyrenees, and La Vendée, appear to have amounted to between 500,000 and 600,000; a force which, though imperfectly disciplined and officered, baffled the greatest confederacy that had at that time been formed in Europe. In 1795 the assignats lost their value, and France was obliged to reduce her army by a third; but its discipline was now greatly improved. During the campaigns of 1795, 1796, and 1797, as well as those in 1799 and 1800, the force maintained by France and Holland was between 300,000 and 400,000. Were the soil of France threatened, or a new declaration of Pilnitz proclaimed, voluntary battalions would assemble as in 1797. France had then 690,000 men under arms, which number could be increased in a few months to 871,000. At the peace of Amiens, Bonaparte kept up a peace establishment of 300,000 men; and after the renewal of war it was raised to 400,000;[3] a force with which he triumphed in 1805 over the united arms of Austria and Russia. His annual levy of French conscripts, though apparently only 80,000, amounted (see Declaration of the Minister at War, 18th September 1809) to 100,000; a supply which, joined to the recruits of his allies in Germany and Italy, kept up his numbers, and even increased them, notwithstanding the wasteful campaigns of 1806 and 1807 in Poland, followed by the no less wasteful campaigns of Spain. In 1812 the force of France and her allies reached their *maximum*, Bonaparte having led against the Russian empire a mass of 360,000 men, whilst there remained in Spain, Germany, and France, a number which carried the aggregate to between 500,000 and 600,000. Need we then wonder that, even after the almost total loss of his troops in Russia, there remained a force competent, with the aid of fresh levies, to withstand the efforts of the allies during two campaigns?

In 1815 Bonaparte, in returning from Elba, found under arms in France about 120,000 men, all of whom, with the exception of a few thousands, rejoined his standard. But so sick were the French of war, that the greatest efforts during the next three months added only 60,000 to this number, and the loss of one battle exposed all the hopelessness of resistance to the allies.

On the second restoration of the Bourbons in 1815, the army had fallen into a very disorganized state, the disciplined soldiers being dispersed, and the ranks slowly filled by new levies. This led to the legislative act of the 10th March 1818, which revived the conscription, but in a mitigated form, and allowing a great latitude in providing substitutes. A recurrence to this method of raising levies was held to be the only effectual method of filling the ranks with men of steady habits; for the army in France, never a receptacle for the refuse of the populace, has in general been composed of young peasantry and labourers of good character. Such was its constitution in the war of the Revolution, and its discipline was exemplary, until Bonaparte adopted the unprincipled practice of making war without magazines, and obliged the soldiers to live at free quarters on the inhabitants. The conscription of the Bourbons was indeed greatly modified, the numbers annually required being limited to 40,000, and the term of service to six years; but the measure is still compulsory, and falls heavily on the middle and lower classes; the alternative for a youth, when drawn, being either to give up his intended profession, or to pay L.40 or L.50 for a substitute. In 1832, the French army amounted to 411,816 men, including 19,036 officers and 3794 children. The infantry, then including the guards, amounted to 264,141 men, including 9505 officers; the cavalry, consisting of various denominations of chasseurs, dragoons, cuirassiers, and hussars, to 51,235 men, including 2805 officers; and the artillery to 32,594 men, including 1190 officers; besides gendarmerie, engineers, &c.; the latter being a numerous and well educated body of officers.

The army is now composed of the imperial guard, the gendarmerie and regiments of cavalry and engineers, and the troop connected with the administrative service of the army. The imperial French cavalry is composed of 12 regiments of cavalry of reserve, *i.e.*, 10 of cuirassiers, and 2 of carbineers; of 20 regiments of cavalry of the line, comprising 12 of dragoons, 8 of lancers, and 1 regiment of guides; of 21 regiments of light cavalry, comprising 12 of chasseurs, and 9 of hussars. There are besides 3 regiments of spahis, and 4 of *chasseurs d'Afrique à cheval.* The organization of the artillery is based on the effective strength of the army in cavalry and infantry. The amount of the corps of engineers is on well-defined principles of military administration, determined by the number of divisions of infantry to which they can be attached, the strong places to defend, and the reserve required for sieges. Troops in France are now said, by the official exponents of the imperial system, to be recruited by voluntary enlistment, and by an appeal to young men of twenty years of age. The effective force of the French army in 1854 before the re-establishment of the guard, and before the new organization of the artillery, amounted in round numbers to 570,000 with 178 field batteries and 1008 guns. By the *budget provisoire* of 1855 the expenses of the *ministère de la guerre* were fixed at L.12,635,911.

---

[2] *Champagnac sur l'armée de France, Mémoirs sur Carnot.*

[3] *Tableau Historique des Guerres de la Révolution.*

The word conscription, which signifies the raw material or levies from which the French army is taken, is somewhat new to the French language, dating only from the year VI. of the Republic (1798). A law of the 10th of March 1818 re-establishes the conscription on bases which, though modified, have not been essentially changed. Every young man is liable to the conscription, and once a year may be selected by "tirage" to serve his country by becoming "chair à canon." To say that the conscription is popular in France, would be to disguise the truth; for large sums are given to procure substitutes, and many *compagnies d'assurance* have been formed to obviate its inconveniences and unpopularity. Every conscript should be sound in wind and limb, but the standard of height required in the French service is much lower than in ours, being only 4 feet 9 inches. Mutilated, lame, gouty, scrofulous, and consumptive men, as well as those who have lost an eye or a finger, who are near-sighted, deaf or dumb, or have lost the incisive teeth, are refused. In time of peace, though less frequently in war, maladies are simulated in order to escape selection. But such poltroons would incur universal odium at a time when the soil of France was threatened. In all military schools, and, indeed from the moment a Frenchman is destined for the service, he is subjected to a military government. Each school has its uniform. The scholars are formed into companies, and are commanded by officers, so that from the earliest years they are subjected to a military hierarchy with but one motive power. Thus the aptitude of the nation for war is strengthened, formed, and created by habit, by education, and by the discipline of the government. (See CONSCRIPTION.)

There is a perfect organization through intermediate steps, by which a direct relation is established between the meanest soldier and the minister of war. This minister is in correspondence with all commanders and generals of divisions of the army. He receives all military despatches; orders the movements of troops; directs and controls all the general and extraordinary expenses of military expeditions. He has the charge of the recruiting, clothing, provisioning, and paying of the army; has the direction of the asylums for invalids at Paris and Avignon; has the sole control of the gunpowder and saltpetre manufactories; of the barracks, military hospitals, arsenals, depots, and magazines of military stores, government foundries and manufactories of fire-arms. His department pays all officers on active service, on half-pay, or on retired pensions, as well as the allowances to officers' widows and orphans. The war minister is the head of the ordnance, and has the direction of the military schools. He has likewise the organization and inspection of the *gendarmerie* as well in Paris as in the departments, and he issues general orders as to the regulation and discipline of the army.

The chief marshal, minister of war, has three aids-de-camp, and four officers on his staff. Independently of these, his private Cabinet is presided over by a *chef-d'escadron* of the staff, and in this Cabinet the opening and registering of despatches takes place, and the departure of military couriers is regulated. In this office are managed what is called *Centralization du travail avec l'Empereur, affaires de franchise et contre-seing,* public audiences, communications with the journals, secret affairs, and affairs which are not within the specialty of any department of the offices.

The *direction (personnel),* which is the first, is under a general of brigade and a colonel of the staff. It contains seven bureaux, each under a chief with a multitude of clerks. The first bureau is devoted to *Correspondance générale "opérations militaires."* The second to the staff and military schools; the third to recruiting; the fourth to military justice; the fifth to the gendarmeric; the sixth to the infantry; the seventh to the cavalry.

The second *direction* or division is the artillery, with sections for the *personnel,* the *matériel,* and the *comptabilité.* The third direction is the engineers, with sections of *personnel, matériel,* and *comptabilité.* The fourth direction is *administration,* in which there are five bureaux, comprising *intendance militaire,* hospitals, clothing, bedding, camp-furniture, pay-audit, internal administration, &c. The fifth direction is devoted to the affairs of Algiers. The sixth to what is called the *depôt de la guerre,* with two sections, comprising geodesy, topography, drawing, engraving, military history, military statistics, archives, maps, and plans. The seventh direction is dedicated to audit and control of accounts, with sections devoted to pensions, aid, military law, &c.

Independently of these, there are eight consulting committees, composed of from six to fourteen superior officers, one a consultative committee for the staff, one for the infantry, one for the *gendarmerie,* one for the artillery, one for fortifications, one for Algiers, &c. There is also a Council of Health in the army, a commission *d'Hygiène Hippique,* and a mixed commission of public works, all under the eye and in the offices of the minister of war. The minister of war is also represented at the *Conseil d'état* by a general of brigade, by four counsellors of state, three *maitres des réquêtes,* two auditors, and a secretary.

The ministry of war, with its general directors, chiefs of division, chiefs and subchiefs of bureaux, subordinate employés, comprising the administrative service; the victualling service, with their directors, accountants, head clerks, writing clerks, porters, servants, messengers, &c., employs about 3000 persons, all working under the immediate direction of one individual. The expense is immense, but there is certainty, celerity, efficiency, and unity of action. No wonder that under a system like this such a genius as Napoleon entered Berlin after a campaign of eighteen days, or that his Austrian campaign scarcely lasted three months. It was the business of the minister of war of that day, and is his business now, to consider the frontiers of the enemy, the advantages and disadvantages of the ground, to obtain information of the resources of the country, and the dispositions and feelings of the army to which the troops of France were and are opposed. With the minister of war there can be no divided power—no opposing interests, no clashing of jurisdictions. He has sole and undivided authority and responsibility in command of the army, and all functionaries connected with the service are not merely subordinate, but obedient to him. There is no board of ordnance, treasury, paymaster-general, secretary-at-war, to interfere with the minister-of-war. The garrison service of France, an open continental country touching the frontiers of Belgium, Prussia, Baden, Switzerland, Savoy, Spain, Holland, imposes on the military service the necessity of being always prepared. Numerous changes of garrison take place with a view to relieve the monotony of the service; and portions of the artillery are always at Paris, Vincennes, La Frère, Toulon, Metz, Strasburg, Besançon, Lyon, Toulouse, and Rennes.

System of military education.

The system of military education is better in France than in England, and the military profession is viewed as it was at Athens, at Sparta, and at Rome; and valour and military skill are more regarded and more appreciated than great civil qualities among us. Skill and address in the art of war are more admired than civil wisdom, or, we fear we must add, than civil liberty. The French cultivate in their military schools gymnastics and bodily exercises, as well as the theory of strategy and war. Young men are instructed in these sciences by rule and precept, illustrated by practice. They read and ponder on the lectures that have been delivered to them; they discuss questions of strategy among themselves; and in all their barracks and garrisons there are libraries of reference, to which they can have recourse. In France, whenever war occurs, it assumes an intellectual complexion, and officers and men devote to it all their vivacious energy and strength.

The French, like the Roman soldiers, are inured to fatigue, and hardened by exercise. Drilled to walk at quick paces, carrying heavy burdens, to climb steep acclivities, and to creep along the sides of precipices, they are early taught that success in warfare is a more constant attendant on boldness, intelligence, address, and audacity, than on mere numbers and brute force. The military art, in truth, becomes among the French a national and patriotic sentiment, and every feeling, thought, and aspiration of the soldier is bound up in the service of his country. No nation is so vain of military successes as the French, and this is one of the reasons why they more easily become soldiers than other men. The Frenchman is by nature and disposition a campaigner. He is of an eager and adventurous disposition, gay, jocund, and somewhat reckless, and disposed to make the best of everything in this world. No man more easily accommodates himself to circumstances, or makes himself more at home in a strange land. He is an excellent marcher, an expert forager, and above all, a skilful cook. He can bake, and roast, and stew, and make sauces, and dress eggs, and produce omelettes in scores of ways. He can darn his own stockings, patch his own coat, and wash his shirt in a running brook, or cobble his shoes under the shade of a tree. He can hut himself with the ingenuity of a beaver, pitch his tent in a salubrious spot, and sing and dance with real light-heartedness. He can subsist on much less than would satisfy an Englishman. There is scarcely a French regiment that does not contain, among officers and men, voluntary societies established for a daily review of their individual progress in military and strategetical knowledge. They discuss and question each other, and enter on particular illustrations most profitable in a professional sense. Tactics, fortification, military geography, and military maxims are in turn handled, so that any man with ordinary intelligence and industry may become a most competent soldier.

The gradations of rank in the French service are *sous-lieutenant, lieutenant, capitaine, chef d'escadron, colonel, maréchal-de-camp, lieutenant-général, maréchal de France.* The number of the marshals of France is limited to twelve; the number of the other ranks, even that of *lieutenant-général*, is very large; for the *état major*, or staff of the army, after a reduction in 1818, consisted of 430 *lieutenants-généraux*, and 260 *maréchaux de camp.* There are on full pay twice as many officers as are necessary for the duty; but the number of half-pay officers exceeds all proportion; for this part of Bonaparte's vast machine has remained, whilst most of the private soldiers have sunk tranquilly into the occupations of the lower classes.

Promotion in the French army never takes place by purchase, and not often by special order: seniority at present determines more than half the appointments, a course which renders promotion extremely slow.

Of the military seminaries of France, the one of highest repute is the *Ecole Polytechnique;* a school for the instruction of young men in mathematics and drawing for the engineer and artillery corps. None but candidates of talent are admitted; and it is well entitled to the name of a nursery (*pepinière*) of intelligent officers. This school was founded in the year III. of the Convention (1794), and no man laboured more to place it on a secure basis than Carnot. It was above all things destined to produce engineers, and some of the most celebrated military and civil engineers of France have been bred within its walls. The number of pupils is fixed at 300, and the age of admission is from sixteen to twenty, and to twenty-five for military men who have two years of effective service *sous drapeau.* Some of the most celebrated men have been professors and teachers in this school, as Lagrange, Laplace, Berthollet, Fourcroy, Guyton de Morveau, Pelletier, Chaussier, Porny, Poisson, &c.

The charge to government of a foot soldier in France does not, in time of peace, exceed L.20 a year; that of the cavalry soldier is nearly double. The pay for either officer or soldier is little more than half the rate in England, and its inadequacy is much complained of. The whole charge of the war department under Bonaparte was about L.20,000,000 sterling. In the year 1833 it amounted to L.8,564,470. The war budget twenty years later, *i.e.* in 1853, was 324,232,663 fr., or about thirteen millions sterling. The war budget for 1855 is 339,861,842 fr.

The gendarmerie are not a part of the regular army, but a corps charged with the police duty, and scattered in small divisions throughout all France. The *gendarmerie* is now (1855) composed of twenty-six legions for the eighty-six departments, and for Algeria; 2dly, of the colonial gendarmerie; 3dly, of a regiment of 2 battalions of the regiment of gendarmerie of the Imperial Guard, formerly called *gendarmerie mobile*, and then *gendarmerie d'élite;* 4thly, of a squadron of *gendarmerie à cheval* of the Imperial Guard; 5thly, of the *garde de Paris*, formerly *garde républicain*, and before that called *garde municipale;* 6thly, of a company of veteran *gendarmes*, amounting in all to about 25,000 men. The *gardes nationales* corresponded to our yeomanry and volunteers.

The National Guard rendered incontestable services by its courage and moderation during the reign of Louis Philippe, first, during the process of the ministers of Charles X. in 1830; secondly, on the 6th June 1832; and thirdly, on the 13th April 1834. In 1848 (see HISTORY OF FRANCE) the reform banquets had many partisans among the National Guard; and after the revolution of February the provisional government suppressed the *compagnies d'élite* of grenadiers and *voltigeurs*, whence the abortive manifestation called *bonnets à poil.* On the 26th June 1851 the National Assembly promulgated a law which organized the National Guard in all France by communes in the departments, and by municipal arrondissements at Paris. By this law it was provided that the National Guard should be composed of all citizens, and that the right of suspension and dissolution should remain with the president of the republic. Till this period the officers, *sous officiers*, and corporals of the National Guard were named by universal suffrage. A mode of election was now adopted somewhat resembling the system under Louis Philippe. The *chefs de bataillon* and the *porte drapeau* were elected by the officers of their battalion, and by an equal number of delegates named in each company; and the *chefs de legion* and the lieutenant-colonels were elected by all the officers of the legion, united with the before-named delegates. This law remained in vigour till the decree of the President of the Republic of 11th January 1852. In consequence of this decree the National Guards were dissolved and re-organized upon new bases, in such localities only as their co-operation should be deemed necessary for the defence of public order. In the department of the Seine the general commanding was charged with this re-organization, which took place by battalion. From the period of the promulgation of this law special corps of cavalry, artillery, or engineers, could only be authorized by the minister of the interior. The chief of the state (now the Emperor) names the officers of all grades on the recommendation of the superior officer commanding in the department of the Seine, and on the recommendation of the prefect in the other departments.

The chief fortifications of France, on the side of Belgium, are the towns of Lille, Valenciennes, Condé, and Douai; on the side of the Alps, Embrum, Grenoble, and Antibes; on the side of the Pyrenées, Perpignan, Bellegarde, Mont-Louis, and Bayonne. The fortified sea-ports are Brest, Toulon, Cherbourg, Rochefort, and Boulogne.

The navy.

The superiority of the English navy over the French existed in ages when our pecuniary means were far inferior; and though, during the middle of the reign of Louis XIV. the French, by financial sacrifices, obtained a numerical superiority, one great battle, that of La Hogue, in 1692, was sufficient to restore our ascendancy. The war of 1741, however successful on the part of France by land, was, particularly towards its close, unfortunate to her at sea. In the succeeding interval of peace, great efforts were made to reinstate the French navy; but the war of 1756, though the French admiral De la Galissonière boasted of a success over Byng, proved doubly disastrous, and at last swept it almost entirely from the ocean. A very different scene opened in the war of 1778, when France, unembarrassed by a continental struggle, was enabled to direct all her disposable resources to her marine, an object of great care and solicitude to Louis XVI. She was then enabled to keep in an effective state about seventy sail of the line, the crews of which, added to those of the frigates and corvettes, formed a total of 60,000 seamen. The injuries sustained by this force, towards the end of the war, were repaired with great diligence during the peace; and to prepare young officers for the sea in preference to the land service, became a favourite object in several of the government schools. In 1791, an official report stated the effective French navy at seventy-four sail of the line, sixty-two frigates, and twenty-nine corvettes; a state of preparation which accounts for the resistance made to our navy by the revolutionary government under all the disadvantages of an unparalleled continental struggle. This proud force, however, disappeared progressively at the capture of Toulon, the victory of the 1st June 1794, and still more in the victory of Aboukir; so that Bonaparte, on his accession to power, found the French marine in a very reduced state. He laboured, however, to reinstate it; the years of continental peace, 1801, 1802, 1803, and 1804, were favourable to his efforts; and in 1805 he boasted of having in equipment sixty sail of the line, a force destined to an early diminution at Trafalgar and St Domingo. The Bourbons, on recovering their crown, found little more than half the force which existed previously to the Revolution. It has since been augmented, and in 1831 it amounted to thirty-five ships of the line, forty frigates, twenty-three corvettes, fifty-seven brigs, twenty-nine galliots and cutters of eight and four guns, twelve steam-boats, sixteen armed store-ships, thirty-two armed transports, two yachts; total, two hundred and eighty-four; and in 1854, according to the last authentic account, it consisted of—

		Guns.
53	vessels—9 carrying 120, 14 = 100, 19 = 90, 11 = 80 or 82 guns—total	5,096
58	frigates—42 = 50 to 60, and 16 = 40 to 46	3,955
39	corvettes	868
101	brigs, schooners, and cutters	1,066
39	corvettes de charge and gabarres	788
290		11,773

Steam Fleet.

3	vessels of the line,	Amounting together to 28,750 guns.
20	frigates,	
30	corvettes,	
64	other vessels,	
407	(1855)	

In the present year (1855) 14 ships of iron (9 being vessels of the line) have been launched, and 32 new vessels are on the stocks.

On the 1st January 1855 the officers of the French navy consisted of 2 amirals, 17 vice-amirals, 37 contre-amirals, 108 capitaines, 238 capitaines de fregate, 658 lieutenants, 614 enseignes.

XI. REVENUE AND EXPENDITURE.

In France the ancient system of taxation and finance was extremely unequal and oppressive. Her various provinces, though they were united under one head, retained many of their own peculiar laws and privileges, which were absurd in themselves, and opposed to the general interests of the empire. Among these was an exemption from certain imposts, to which some were subjected, and consequently over-taxed; and others, again, contributed a certain quota of revenue to government, which they raised by taxes imposed by their own local authorities. The consequence was, that no uniform system of taxation could be established throughout the country. The taxes on many commodities were higher in one province than in another; and custom-houses were accordingly established on their respective frontiers, to prevent the importation of goods until they had paid the duties. In this manner, owing to the inequality of taxation, commodities could not freely pass from one district of the country to another; and the kingdom was thus broken into separate divisions, to the great interruption of trade. The partiality shown to the privileged orders was another serious grievance in the ancient system of French taxation. The taxes by which the public revenue was raised were, first, the *taille*, a tax on real property, or on income derived from commerce and industry. From this tax the lands of the noblesse and clergy were exempt. "The tax was called *taille*," says Borel, "because the peasant collectors, not knowing how to write, marked down what they had received on a wooden tally." Secondly, the *vingtième* was a tax of one twentieth on property, from which the clergy alone were exempted.[1] Thirdly, a poll tax was levied on all classes indiscriminately. Many of the taxes were farmed by rich capitalists called farmers-general or *fermiers-generaux*, who paid annually into the treasury a fixed sum, and collected the taxes from the people. Those farmers-general held the monopoly of the manufacture and sale of tobacco and salt; and also the *octroi*, which was a duty on all articles entering Paris and other large towns. The power delegated to these contractors was the source of grievous oppression to the people. The duties called *aides* were imposed on spirituous liquors and other articles of consumption; they also included duties on all articles worked in gold or silver, on wrought iron, playing cards, leather, paper, starch, &c. These duties levied by collectors for the benefit of government were abolished by the National Assembly in 1790. The *corvée*, which consisted in so many days' labour annually, of men, horses, oxen, carriages, &c., was nominally applicable to the maintenance of roads. The tax was payable either in money or in labour. This system of taxation, so prejudicial to internal commerce, was to a certain extent reformed by Colbert, the minister of Louis XIV., who, though his views in regard to the principles of commerce were narrow and illiberal, yet improved in many particulars the system of taxation, by rendering it more uniform, and thus breaking down the barriers which obstructed the free intercourse between the different provinces. Under his administration the public revenue of France amounted in 1682 to L.5,000,000.

The long and expensive wars of Louis XIV. produced a great accumulation of debt (nearly L.100,000,000 sterling), which, after his death, was lessened by an appeal to a singular privilege, of which advantage has often been taken in France, viz. that a new sovereign is not bound to pay the debts of his predecessor in full. During the eighteenth century the revenue of France increased progressively, but more slowly than that of England; the vicious system of farming the taxes still continued. Necker, appointed to office in 1776, endeavoured to teach the French court the value of publicity in financial statements, and exhibited the rare example of a war conducted for several years without new taxes, the supplies being found by loans, the interest of which was provided for by successive retrenchments in the public expenditure. His successor, M. de Calonne, pursued a very different course, and was found altogether incapable of the measures necessary to remedy an annual deficiency of L.2,000,000. The revenue of France was then about L.22,000,000 sterling. The sum required for payment of the interest of the public debt was nearly L.10,000,000,[1] leaving only L.12,000,000 for the army, navy, civil list, and other public expenses.

---

[1] This tax was established in 1750, and was levied upon all property of whatever description. In 1754 it was taken off the amount of income arising from personal industry.

Such was the state of the French finances at the era of the Revolution of 1789, which was followed by invasion on the frontier, and in the interior by all the confusion consequent on the reign of terror. In this era of confiscation and judicial murder, the national debt could hardly be respected. It was not, however, openly cancelled, but the interest was issued in assignats of no value except for purchases of national property. At last, in 1798, on an approximation to regularity in the management of public business, there was passed a law declaring that one-third of the old national debt should be sacred, and the interest on it payable in *bons*, or paper receivable in discharge of taxes. This third was called *la tiers provisoire*, but its price in the market continued very low until Bonaparte succeeded to power, and placed Guadin, afterwards Duke of Gaeta, at the head of the treasury, when means were found to redeem the public funds from their depression, and to resume the payment of the dividends in cash. The amount of the revenue was greatly impaired by the general confusion of the revolution. In 1799 the expenditure exceeded the receipt by L.8,000,000 sterling.[2] A partial reduction of expenditure, and improvements in the collection of the taxes, brought in 1803 the receipts to L.19,500,000, whilst the expenditure was L.20,000,000. In subsequent years both received a progressive augmentation, and in 1813 the revenue derived from France, exclusive of conquered territory, was about L.27,000,000. On the restoration of the Bourbons in 1814, the public debt, funded and unfunded, did not exceed L.123,000,000;[3] its interest L.7,900,000. France had thus a fair prospect of financial prosperity, when the return of Bonaparte, and a second invasion by the allied troops, overthrew public credit, and produced a national loss and a general derangement of trade. It has been estimated that the return of Napoleon from Elba, which led to the second invasion of France by the allied troops, occasioned a loss to the country of 4,000,000,000 of francs. The direct loss, which included the expenses paid to the allied powers, and those incurred by the maintenance of their armies, placed in cantonments throughout France, may be estimated; but the indirect evils occasioned by the ravages inseparable from the invasion of a hostile army, by the confusion and derangement of all commercial relations, and the impossibility of collecting the revenue in such a time of trouble, cannot be summed up in money. At the same time there are scarcely any national difficulties which may not be overcome by the energies and industry of a free and intelligent people such as the French. With an inconsiderable addition to her debt, France has defrayed all these heavy expenses, the contributions imposed on her by the allied powers, the expenses of the temporary maintenance of their armies, and her own warlike expenses. For this purpose, however, it became necessary in 1815 to impose additional taxes. In 1817 a loan was required of 392,989,000 francs; and in 1818, to defray the extraordinary contribution of 575,807,197 francs, paid in that year to the allies, the minister had recourse to another loan of 220,510,718 francs; whilst by the taxes which had been imposed, the revenue of that year was carried to L.35,000,000.

Besides the public revenue of the empire, the communes raise a revenue for their own local expenses. According to the latest published accounts, this revenue arises partly from *octrois*, which amount throughout France (there being 1436 *octrois*) to 95,176,602 francs, and partly from other sources, the whole of which amounted to 230,633,909 francs in 1850. The total of the ordinary ways and means of France in the *Budget Provisoire* of 1855 amounted to 1,528,110,288 francs. During the administration of M. Vilèle, the five per cents. in France were converted into a three per cent. fund, at the rate of 133·33 cents. for every hundred of the five per cent. stock; so that the whole five per cent. stock, bearing an annual interest of 30,574,116 franes, was converted into a three per cent. fund, of which the capital was increased one-third. The effect of this transaction was in reality to reduce the interest on the five per cent. stock to four per cent., by which he saved annual interest to the amount of six millions, though by a very useless complexity in his operations. The interest on the public debt of France, thus reduced, may be stated as follows:—

It amounted in 1855 to 418,370,442 francs. The sinking fund or *caisse d'amortissement*, ceased altogether its operations on the 14th July 1848. In the thirty-two years of its operation the *caisse d'amortissement* liberated the country from liabilities to the amount of 1,633,474,090 francs, and placed at the disposition of the treasury, from 1833 to 1848, 1,016,693,856 francs.

System of taxation.

The ancient system of taxation in France was subverted by the National Assembly in 1791, and new taxes were substituted in lieu of those formerly in force. These consisted of direct and indirect taxes. The direct taxes are, 1. *Contribution foncière*, or land-tax; 2. *Contribution personelle et mobilière*; 3. A tax on doors and windows; 4. *Droits de patente*, or a license duty on particular trades and professions, and a duty on mines.

The *contribution foncière* is raised equally on all lands and houses in proportion to their nett revenue. There are no longer any exemptions in favour of the nobility since the first revolution in 1789. The imperial domains and the property of the state are alone exempted. The *contribution personelle et mobilière* is divided into two parts. The first is a species of poll-tax, rated at three days' labour, calculated in money value to be from 10 to 30 sous per day, and levied on all males above eighteen years of age. The *contribution mobilière* is a house-tax levied on all rents from 200 to 2500 francs. For the *contribution personelle*, the *octroi*, which is a custom-duty on all goods entering a town, is substituted in Paris and other large cities. The tax on street-doors, gateways, and windows, varies in proportion to the size of the town in which the house is situated, and also in proportion to the size and value of the house and the number of windows. It is regulated by a tariff, in which are two divisions. The *droits de patentes* or license-duty is levied on every person following a profession, trade, or business; and is divided into two heads—the proportional tax, or the fixed tax, which depends on the extent and population of the town where he exercises his profession. A merchant pays from 40 to 500 francs per annum, according to the population of the place where he resides, and an additional ten per cent. on the rent of his dwelling-house. Bankers in all cases pay 500 francs a-year; and there is in like manner a fixed rate for other inferior trades and professions. The duty on mines is in proportion to the extent of the surface, and also to their nett produce.

---

[1] Report of Camus to the National Assembly in September 1790.

[2] Gaudin, *Notice Historique des Finances de la France.*

[3] Bignon, *Exposé Comparatif de la France.*

The law which fixes the amount of the direct taxes also determines the quota which each department is required to pay. This is announced by the minister of finance to the prefect of the department, who communicates it to his sous-prefect and to the mayors. The sum thus assigned by the prefect to each arrondissement is subdivided by the councils of the arrondissement and by the communes; and the amount allotted to each is apportioned among the inhabitants by persons appointed for that purpose, called *repartiteurs* or assessors. These assessors regulate the amount of taxable property, and they fix the scale. The land-tax is however very unequally assessed, amounting in some departments to six per cent., whilst in the department of the Seine it is seventeen per cent. The equalization of the land-tax has always been accounted a capital object in the financial policy of France; and with this view a minute survey and measurement of all the landed property in France (termed the *cadastre*) was begun in 1808, and finished in 1847. The *cadastre*, accurate as it generally is, cannot, however, be considered as the expression of actual facts. The *propriétés imposable*, or taxable property, consists, according to the *cadastre*, of 25,581,658 hectares of cultivable land; 5,159,226 hectares of meadows; 2,090,533 hectares of vines; 628,235 hectares of orchards, nurseries, and gardens; 4,175 hectares of mines; and 17,400 hectares of lakes, ponds, &c. The inequality of the land-tax has long been a subject of loud and just complaint; and various plans have been adopted for a more accurate classification of the land. But these have generally proved inefficient and unsatisfactory.

The indirect taxes consist chiefly of fourteen principal kinds—of the *droits réunis* or excise duties on articles of consumption, of stamp duties, registration duties, duties on carriages, on canals and ferry-boats, on gold and silver plate. A revenue is raised from the monopoly of tobacco and gunpowder; from the post-office; the *octroi*, or custom duty on all articles entering large towns, one-tenth of which goes to the imperial treasury, the remainder being applied to local expenses. The customs form an important branch of the French revenues.

The *droits réunis* or excise duties are laid on wine, brandy, &c., which pay one-and-a-half francs per hectolitre of 120 English quarts, on being removed from one place to another.[1] Wine in bottles pays 10 francs per hectolitre on its removal; cider, perry, and mead, pay 80 centimes per hectolitre. Ten per cent. of the above duty is paid on their removal from the wholesale warehouse. Prior to 1830 a duty distinct from the octroi was levied on the entry of all wine or spirituous liquors into communes the population of which amounted to 1500 and upwards. All communes whose population does not amount to 4000 are exempted from this tax; and a new tariff has been established, rising progressively from 4000 to 5000 inhabitants, in proportion to the estimated wealth of the departments, which are divided into four separate classes—a very vague, as we should suppose, and uncertain standard of taxation. There is a further duty on wine and liquors sold by retail, which since 1830 has been reduced from fifteen to ten per cent. A reduction of three per cent. on this duty is made to dealers, and of twenty-five per cent. if the wine be grown by the retailer himself. Strong beer pays a duty of 2 fr. 40 c., and small beer a duty of twelve sous, per hectolitre. Retailers of liquors must take out a distinct licence, which varies, in proportion to the size of the town, from six to twenty francs.[2] Proprietors of public carriages pay one-tenth of the price of each place for passengers, a third being deducted for vacant places, and one-tenth of the price received for merchandise. Private carriages are subjected to a moderate duty, according to their size, of 40 fr. per annum for a carriage with two wheels, and holding two persons; and of 150 fr. per annum for a carriage with four wheels, and holding nine persons. The *enregistrement*, or registration duties, embraces a variety of transactions, where property is conveyed or given away by marriage-settlement or otherwise. There is a duty on gifts *inter vivos*, which increases with the distance of the relation between the parties. It was modified by an ordonnance of Louis Philippe in 1832. The duties payable on registry are either fixed or *ad valorem*; the fixed or certain duties apply to common certificates, those of life or residence, account books, bills of lading, appointments of arbitrations, valuations of furniture, and the like. The *ad valorem* duty applies to all bonds or obligations, discharges, judgments, deposits or releases of sums of money, and for every transfer of property, &c. The stamp duty applies to receipts, bills of exchange, newspapers, handbills, playbills, admission cards to public places, and upon paper used for civil and judicial *actes*.

The total received from the *impôt direct* in 1854 was 411,273,000 francs. In 1853 the sum received was 420,064,000 francs, which shows a deficit of nearly nine millions of francs in 1854.

The total receipts of the *impôts indirects* in 1854 were 847,260,000 francs. The impôt on salt produced in 1854 a sum of 33,270,131 francs. The total of "droits" received in 1854 amounted to 149,337,510 francs.

Land carriage or roulage 31,000,000 of tons, the mean transport at 15 leagues, at the mean price of 1 franc per ton	465,000,000 fr.
The public voitures which travel 18 leagues per day, in place of the common carriages of 8 or 10 leagues, yield, per annum	60,000,000 ,,
The duty on the public conveyances returns 6,000,000 francs; three-fourths are derived from the passengers, and one-fourth from the goods they convey.	

The share capital of the French railways in 1848 was L.49,044,000 sterling.

The total merchandise conveyed per transit in 1844, was in value 229,820,795 francs. In 1854, = 54,926,640 francs official value.

Value of wine, spirits, beer, and cider consumed in France, reckoned at 500,000,000 francs, give 311,000,000 francs wine, 54,000,000 francs brandy, 59,000,000 francs beer, and 76,000,000 francs cider.

The duties levied on this branch of the French revenues produced L.5,483,765 in 1852 and L.5,505,686 in 1853. In France these duties are laid on in many cases more with a view to restriction and monopoly than to revenue. France sacrifices a large revenue for the encouragement of the colonial monopoly; paying for the produce of the colonies an exorbitant price, and afterwards, as in the case of sugar, the staple article that is imported from the colonies, giving a great portion of the duty as a bounty on its exportation to foreign countries, to indemnify the exporter for the loss that he would incur if he were selling the sugar at its ordinary price in the markets of Europe. In 1830 the gross receipts from the sugar duty amounted to L.1,397,340, of which one-third, namely, L.420,903, were paid back in bounties on the exportation of the surplus. Thus the nett duty only amounted to L.976,437, while in

---

[1] According to the existing law in France, wine, cider, perry, and hydromel are subject to three principal duties or imposts; 1. *Droit de circulation*; 2. *Droit de detail*; 3. *Droit d'entrée*. Any one of the liquors named may be subject to two of these imposts, but never to three at the same time. Alcohol pays a *droit particulier de consommation*, to which is added the *droit d'entrée* into the localities subject thereto. Beer only pays a *droit de fabrication*. Wholesale dealers, retailers, distillers, *liqueur* makers, are subject to a *droit de licence*. The city of Paris is, however, under special regulations in this respect, and the *droit de circulation* is subject to a variety of minute modifications only interesting to the French retailer of wine, beer, or spirit. Every sale less than a *hectolitre* in cask, or 25 *litres* in bottles, is considered a retail sale. The *droit d'entrée* and the *droit de consommation* are also the subject of minute regulations and exceptions, into which it is not necessary to enter. Paris wine-merchants pay no licence, nor are there any private bonded cellars as in England.

[2] In a majority of the departments, distillers pay 50 francs and brewers 30 francs licence, and *marchands en gros de boissons* 50 francs. *A tarif du droit d'entrée*, based on the population of the communes of four different classes, ranging from 50,000 to 4000, as well as a *tarif des droits de licence* will be found appended to the *Enquête Législative sur l'impôt des Boissons*, ordered by the law of the 20th Dec. 1849.

1822, though the quantity of sugar consumed was only 1,086,596 cwts., or 281,075 cwts. less than in 1830, the nett amount of the duty was L.1,234,653. The consumption of sugar in France in 1847 only reached to about 2,570,000 cwts. It is by means of heavy custom-duties that the French legislators endeavour to preserve the monopoly of the home market to their own manufacturers, by which policy they compel the French community to buy at a high price the inferior articles of their own manufacture, rather than the better articles of the foreigner at a lower price.[1] The increased numbers and superior vigilance of the custom-house officers have been still counteracted by the new expedients and persevering ingenuity of the smuggler.

The frontier of France is the scene of this persecution against commerce, where all the illegal, daring, and ingenious resources of the contraband traders are called into activity. Amongst other expedients, they trained packs of dogs, according to Messrs Villiers and Bourtry, to carry prohibited goods across the frontier. These dogs being conducted to the frontier, are kept without food for many hours; they are then beaten and laden with goods, and are started on their travels when it begins to grow dark, and reach the abodes of their masters as soon as they can, where they are well treated, and receive a full meal. According to the accounts of the French custom-house, 40,278 of these dogs were destroyed in the year 1830, on which account premiums were paid to the custom-house officers to the amount of 40,278 francs. That the trade, though it may be obstructed, is not prevented, is evident from the circumstance that there are regular rates of insurance on the conveyance of contraband goods into France, varying from ten to seventy per cent. A revision, and if possible a reduction, of these heavy duties would be the true policy of France.[2] Monopoly was never yet the source of commercial greatness in any country.

XII. NATIONAL INCOME AND CAPITAL; POPULATION.

Cadastre.

Of the official surveys of the French territory, by far the most minute and accurate is the *cadastre*, a survey which became indispensable from the time it was determined to exchange the taxes on consumption for taxes on produce. A return of the rent of land, such as was made under the property-tax act in England, would not have been practicable in France, where so many thousands of petty lots are cultivated by their proprietors. At first the *cadastre* proceeded on the plan of an estimate *par masses de culture*, or continuous valuation of extensive tracts; but this proving unsatisfactory, it has been conducted since 1807 on a plan of such minute detail, as to give the value of every separate *parcelle* or patch of land. The progress of this minute survey of the landed property in France has been retarded by many causes; and in 1830 not above two-thirds of the land had been surveyed. It was estimated in the report of one of the committees of the chamber in 1832, that it would still require from that period about eight years, and an expense of above L.2,000.000 sterling, to complete it. They had only surveyed thirty-one millions of hectares, or sixty-eight millions of acres. The annual expense of the survey is L.120,000.[3]

The wages of mechanics are so fluctuating and various, that a satisfactory statement of them can scarcely be produced. It may, however, be assumed that they are generally twenty or thirty per cent. lower than in England. The rate of wages of the agricultural population was thus estimated in 1851:—

		Francs.
6 millions of men, at 1 franc 50 centimes per diem		1,800,000,000
6 millions of women, at 75 centimes	„	900,000,000
6 millions of children, at 25 centimes	„	3,000,000
18 millions of agricultural labourers paid yearly		3,000,000,000

Expense of living.

A quarter of a century ago the difference in the expense of living in France and in England was about a third less in favour of England. As far as regards provisions, this difference was somewhat greater; but it received a counterpoise in the cheapness of our fuel. Paris is now as expensive compared to the rest of France, as London is compared to the rest of England. In 1855 prices were generally on a par with prices in London, and in house-rent and the prices of lodgings and fuel, Paris exceeds London.

In the end of the seventeenth century, the territory of France, when very nearly equal to its present extent, appears, from the report of the intendants or provincial governors, to have contained about 20,000,000 of inhabitants. This number was found, by the census made by order of the National Assembly, to have increased nearly a third in the course of a century; the amount, in 1791, being 26,363,600, a number which, by computation, made in 1817, had further increased to above 29,000,000. In the year 1820 the population was 30,451,187; and, according to the ordonnance of January 1832, it amounted to 32,661,678. By the census of 1851 it appears that the population of France was 35,781,628. The marriages in 1832 and 1833 were annually about 236,996, and the deaths about 785,268, of which 395,250 were males, and 388,018 females. The births were 967,533, of which there were 498,707 boys and 468,826 girls. The number of illegitimate children was then 68,081. In 1852, twenty years after the period here spoken of, the total number of births was 965,080, of which 895,236 were legitimate, and 69,844 illegitimate. The number of children still-born in 1852 amounted to 37,901, the number of deaths to 811,695, and the number of marriages to 281,360.

---

[1] On the 1st August 1847 a uniform duty of 45 francs per 199 kilogrammes was imposed on *Sucre brut Français*, native as well as colonial. In the space of three years the native product has more than doubled. Native sugar to the value of 30,000,000 fr. was manufactured in 1844, and to the value of 67,000,000 fr. in 1847. We know from reports made to the council of state by M. Behic, and to the legislative assembly by M. Beugnot, that the production of sugar in the French colonies has fallen lower than it has been for twenty years.

[2] The duties upon *matières premières* and upon corn date from the restoration. The first republic and the first empire favourably considered the raw material so necessary to labour; under the restoration the object in laying on these duties was in the hope, the vain hope, of creating a territorial aristocracy as in England. Impelled by the scarcity of 1853, recent decrees of Louis Napoleon have relaxed the prohibitive system and given a provisional liberty to the trade in corn and meat. An imperial decree of the 22d November 1853 reduces the import duties on coal and iron. Coal paid with the *decime*, 55 centimes per 100 kilogrammes, from Sables d'Olonne to Dunkirk; on the rest of the French coast it paid 33 centimes. On the land frontier the duty was 165 centimes, excepting by the Meuse, and in the department of the Moselle, where the duty was 11 centimes. Thence from d'Olonne to Dunkirk, and onward by land to Halluin, there is but one duty of 33 centimes by French ships, and 88 by foreign bottoms. The rest of the maritime frontier is assimilated to the greater part of the land frontier.

[3] It is positively stated in the *Statistique de la France*, published by the minister of agriculture, commerce, and public works, in 1855, that the *cadastre* was finished in 1847, and it is as positively averred by M. Achille de Vaulabelle, the historian of the restoration, and minister of public instruction under the republic, that the work is unfinished, that there are not merely arrondissements, but whole departments not *cadastré*. One thing is certain, that in some departments proprietors pay 8 per cent. of their nett revenue, whereas in others they pay twice and thrice as much.

The estimates of population in France subsequently to 1791 are formed, not like our population returns on an actual survey, but by adding for the period which has intervened, the births, and deducting the deaths, of which an accurate record is kept in the public offices.

The ratio of the increase of population in France is greatest in the lower classes; the middling and upper ranks have seldom large families. In that country, as with us, the population evidently increases faster since the adoption of vaccine inoculation.

XIII. GOVERNMENT.

The charter in virtue of which Louis XVIII. ascended the throne of his ancestors was the basis of the government of France so long as it continued a monarchy.

By that instrument, the king was declared the supreme head of the executive power, in whom was vested the power of declaring war and making peace; the command of the national force, whether by land or sea; and the nomination of all ministers, ambassadors, and other public functionaries, civil and military.

The legislative power was exercised under the monarchy by two chambers, the Chamber of Peers and the Chamber of Deputies, in conjunction with the king, without whose concurrence no measure had the authority of law.

Chamber of Peers.

The Chamber of Peers consisted under the monarchy of no definitive number, as the king had the unlimited power of creating peers. The number of peers in 1826 was 214, and in 1827 it was increased to 290 by the creation of seventy-six new peers. But this great and sudden addition to the peerage being considered as an unconstitutional exercise of the prerogative by Charles X., was declared null and void after his abdication; and in 1833 the number of peers, including five princes of the blood and several new creations, only amounted to 262. Louis XVIII. could by his prerogative convoke this chamber when that of the Deputies was not sitting. But this power was withheld in the new charter of 1830, excepting in the case of the chamber sitting as a court of justice; and on such occasions it is strictly confined to its judicial functions. No meeting of the chamber could take place except by an express order of the king; and it is convoked by his majesty at the same time as the Chamber of Deputies, the session of the one commencing and finishing at the same time with that of the other. A peer of France under the monarchy of the elder and junior Bourbons was admitted into the chamber at the age of twenty-five; but was not admitted to the exercise of any prerogative until he had completed his thirtieth year. The chamber under Louis XVIII., Charles X., and Louis Philippe took cognizance of high treason, and of all crimes committed against the security and peace of the state. Those who were members of the senate during Bonaparte's reign were created peers after his abdication, and their pensions of L.1500 a-year were confirmed. By an ordonnance of Louis XVIII, no person could be created a peer unless he possessed a certain entailed property in trust or in the funds, producing, in order to enable him to support the title of a duke, a clear income of 15,000 francs, or L.600 per annum; for the title of a marquis, 10,000 francs; and for viscounts and barons, 5000 francs. In order to exercise the privileges of a peer of France, double the amount of clear income is required.

Chamber of Deputies. The popular branch of the French legislature consisted under the monarchy, according to the original provisions of the charter, of 258 members, who were elected by a committee of voters (*collège électoral*), each paying direct taxes to the amount of L.40 per annum, and who were delegated to elect a deputy by a lower class of electors, whose qualification was the payment of L.12 per annum of direct taxes. One-fifth of the chamber was to be renewed every year; so that every five years the whole would be re-elected anew. In 1817 a law was passed abrogating the intermediate class of electors, and giving to all the voters the right of immediately electing the deputy; and in 1821 the plan of renewing the chamber by one-fifth at a time was also abrogated, and a law was passed for dissolving and re-electing the whole assembly at once. In 1831 a new electoral law was passed, reducing the qualification of the electors to 200 francs (L.8, 6s. 8d.), and also the age from thirty to twenty-five years, and reducing the qualification of deputies from forty to thirty years of age, and the pecuniary qualification from 1000 to 500 francs. It was estimated, that by thus lowering the pecuniary qualification of electors, the number would be increased from 100,000 to 190,000. (See HISTORY OF FRANCE.)

The French Chamber of Deputies under the monarchy consisted of 430 members, chosen for 86 departments. The original charter of Louis XVIII. assigned to the monarch the exclusive right of proposing all public measures; and it was necessary in proposing any new law to move an address to his majesty, praying that it might be presented to the chamber for its adoption. The charter of 1830 dispensed with this form, and gave the right of initiating laws to all the branches of the legislature, with the exception of taxation bills, which originated with the representatives of the people. When the session commenced under the monarchy, *bureaux*, or special committees, nine in number, were formed, and were periodically renewed; and when any new law was presented to the chamber on the part of the king, it was referred in the first instance to these special committees; if the law was approved by two or more of them, it was reported by the chamber, when the principle of the measure was discussed by the chamber, and the clauses voted article by article. The decision of the *bureaux* was reported by the chairman or *rapporteur* to the whole chamber; which frequently pronounced an opposite decision. The special clauses of a law were voted by *assis et levée*; those who are for the law, the *ayes*, rising, and those who are against the law, the *noes*, keeping their places. The vote on the whole measure was by secret scrutiny, the ayes being indicated by white balls, and the noes by black ones, thrown into an urn placed on the tribune of the chamber. The sittings of the chamber were, under Louis XVIII., Charles X., Louis Philippe, and the Republic, public; but on the demand of any five members, all strangers were excluded. No deputy could be arrested for debt during the sitting of the chamber, nor within six weeks previous to its assembling, or six weeks subsequent to its prorogation in the time of the monarchy; and if arrested at any other period, he must be liberated during the session; nor could any deputy be arrested or prosecuted for a criminal charge, except he were detected in the act, unless by permission of the chamber. It will be remembered (see HISTORY) that the Duke de Praslin was not arrested by the police. The senators of Bonaparte received each a salary of 10,000 francs per annum. The deputies to the chamber received no salary under the monarchy. The president, the secretaries, and the officers attached to the chambers, such as *questeurs*, *huissiers*, &c., were the only persons paid. The salary of the president was, under the elder Bourbons, 100,000 francs per annum, besides a furnished hotel, horses, equipage, &c. But it was reduced to 4000 francs per month, payable only during the session in the reign of Louis Philippe.

Executive government. The executive department of the government was administered by the king and his cabinet council, consisting of nine ministers, viz.—

1. The minister of finance, whose business it was to receive the taxes from the receivers-general, and all the other revenues of government. He disbursed, and still disburses the payments for the other departments of the state, for the interest of the public debt, and all pensions, &c. To this ministry are attached certain other offices, the chiefs of which are called directors; namely, directors-general of taxes, customs, registries and domains, ports, woods and forests, and the mint. The salary of the minister of finance was reduced by the Chamber of Deputies under Charles X. in 1828, from 150,000 to 120,000 francs per annum; and the salaries of the directors vary from 40,000 to 50,000 francs per annum. The revenue was under the monarchy, and is still, conveyed to the treasury through various subordinate offices. There is a *percepteur* or collector in each commune, who pays his collections to the special receiver for each arrondissement, who transmits the revenue to the general receiver of taxes for the department, by whom it is, lastly, remitted to the office of the finance minister.

2. The minister of the interior. This minister was, under the monarchy, and still is under the empire, one of the most important, if not the most important of the functionaries of the state. He is in direct correspondence with all the civil authorities of the kingdom; no local tax can be imposed, nor any disbursements made, in any of the departments, districts, or communes, without his authority. The general police of the kingdom, with all its various details, is under his superintendence; besides poor-houses, charities, and hospitals, the national guard of France, the censorship of the theatre, the royal institute, the public libraries and government archives, the examination of all passports, and all reports from prefects and sub-prefects of departments. He takes cognizance also of the press. He has directors under him, who relieve him from the trouble of details. His salary is 120,000 francs, and there are at least 204,000 officials under his orders.

3. Minister of justice and keeper of the seals. He is at the head of the law department, though he seldom presides in any court of justice. He corresponds with the law officers of the crown throughout France, and takes cognizance of all cases of criminals after conviction, and of all applications for royal mercy. There are more than 30,000 officials under his orders. His salary is 120,000 francs.

4. Minister of marine, who has the direction of the navy and the colonies of France. The dockyards and maritime prefects are under his authority; 10,000 workmen and mechanics are employed in the building or repairing of ships, under about 400 *maitres entretenues*. The colonial affairs of the empire are also under the supervision of this minister. His salary is 20,000 francs.

5. Minister of foreign affairs. His duties are expressed in his designation. All passports to cross the frontiers must be nominally countersigned by him. His salary is 150,000 francs.

6. Minister of war. He superintends of course the whole service of the army. He has also the sole control of the gunpowder and saltpetre manufactories, barracks, military hospitals, &c., and the government founderies and manufactories of small arms. He has also the charge of organizing and inspecting the corps of gendarmerie of Paris, as well as in all the departments. Salary 120,000 francs.

7. Minister of ecclesiastical affairs.[1] His salary is 120,000 francs.

8. Minister of public instruction. His functions are strictly con-

---

[1] The ministry of ecclesiastical affairs was suppressed in 1829, and the duties were transferred to the minister of public instruction. Under the elder Bourbons the minister of ecclesiastical affairs was in direct correspondence with the court of Rome. He then published all briefs, bulls, &c., nominated all archbishops, bishops, and other clerical functionaries, and had the administration of the expenses of cathedrals, churches, &c.

fined to secular education. He nominates the different functionaries in the public academies and faculties, authorizes the opening of private boarding-schools for both sexes, and regulates the works to be used in these seminaries; he grants diplomas in law and medicine, superintends the receipts of colleges, fixes the pensions of retired functionaries, grants aids and indemnities to collegiate corporations, and generally takes cognizance of all institutions for public instruction. He has now a superior or imperial council of public instruction. His salary is 100,000 francs.

9. Minister of commerce and manufactures. This is a new office, of which the business partly belonged to the minister of finance and the minister of the interior. In 1829 the minister of commerce was suppressed, and the business was transferred to the home office. In 1830 a ministry of public works was created. The minister of commerce corresponds with the chambers of commerce; nominates exchange-brokers, with the exception of those in Paris, who are nominated by the minister of finance; examines all demands made for the establishment of assurance offices, their rules and regulations; grants patents for inventions; establishes or suppresses fairs or markets; decides on the qualifications of candidates for the office of judge in any of the commercial courts; and has an especial jurisdiction over all that may promote the prosperity of commerce and manufactures. His salary is 120,000 francs.

Besides these cabinet ministers, the Bourbons had a privy council, the members of which were seldom summoned, the public business being entirely managed by the cabinet council.

Under the last monarchy each of these ministers presented to the Chamber of Deputies his own budget of expenses, which was examined by a committee specially appointed for the purpose. It was competent for these committees to propose a reduction in the items of these ministerial budgets, which might be adopted by the chamber. After these various budgets had been considered and discussed, the general account of the national expenditure was considered and put to the vote.

The council of state.

Ministers of state were nominal functionaries under the monarchy, and the appointments were generally given to retired cabinet ministers, as a reward for past services. The pension was formerly 20,000 francs per annum, but after the revolution of 1830 it was restricted to 12,000 francs a-year.

The council of state was a favourite institution of the Emperor Napoleon, and under the consulate and the empire he loaded it with administrative business. Sometimes he used it to control the acts of his ministers, and generally he submitted to it the most delicate and thorny affairs of his government. The first restoration reconstituted the council of state by royal ordonnance of the 29th June 1814. The peculiar organization then given to it was suppressed in the Hundred Days, and again re-established by the second restoration on the 23d August 1815. After the revolution of 1830 seven projects of law were submitted to the Chambers with a view to improve the council of state. The seventh alone was discussed, and carried in the session of 1845. It had scarcely been more than put into execution before the revolution of February broke out. The provisional government commenced by reducing the number of councillors of state from thirty to twenty-five. It attached great importance, however, to the council of state, a whole chapter being dedicated to that subject in the republican constitution. The imperial decree of the 25th January 1852 has definitively regulated the council of state, rendering its functions among the most important in the empire, imposing on it the preparation of all projects of law, and the sustaining of those projects before the legislative body. The council of state is necessarily called upon to give its opinion upon all decrees concerning the public administration.

The council of state now (1855) consists of a president and vice-president, of from forty to fifty councillors of state in ordinary service, of councillors of state out of particular sections, whose number cannot exceed fifteen; of councillors of state in extraordinary service, whose number cannot exceed twenty; forty *maîtres des requêtes* divided into two classes of twenty each; a general secretary having the title and rank of a *maîtres des requêtes.* The ministers have their rank, seats, and voice in the council of state, and the members are named by the emperor. Neither councillors of state nor masters of requests can be senators or deputies of the legislative corps, their functions being incompatible with all other salaried functions. The councillors of state on actual or ordinary service received under the monarchy a salary of 12,000 francs a-year, a deduction being made if they enjoyed any other situation of emolument under government. To the council of state are attached the *maîtres de requêtes,* appointed likewise for ordinary and extraordinary service, but some are merely honorary. Their business is to draw up all acts of council, for which they receive a salary of 6000 francs a-year. The office of *maître de requêtes* was considered as the first step towards the rank of councillor of state.

Audit office.

Audit office, or *cour des comptes.* It is the business of this court to receive and examine all the accounts of the different ministers, and those of the receivers-general and prefects of the departments; and to certify the correctness of the general accounts published every year by the minister of finance. The ordinary business of this court was under the monarchy managed by three chambers, each having a president; and there was then also a chief president, who sat when these chambers were united; but a fourth temporary chamber was instituted by decree of 15th January 1852. There is also a councillor of reference in each chamber (*reférendaire*), whose duty is the verification of the accounts; also a procureur-general, whose office corresponds to that of solicitor of some of the public offices in England, and who sees that all the necessary accounts are delivered into this office within the period fixed by law, and who, in case of neglect, proceeds against the offending parties for the penalties they have incurred. There is likewise a chief registrar, in whose custody remain all the accounts and vouchers transmitted to his office. The court is composed of a first president, 3 presidents, 18 *conseillers, maître de comptes,* 80 *conseillers referendaires,* in all 103 magistrates. The whole court meets every three months in public to go over the accounts of the three preceding months.

Revenue of the king.

The revenue of the king, or the civil list, in the time of the monarchy, was fixed at the restoration, by the budget of 1814, at 15,510,000 francs per annum; and a further grant was made to the other branches of the royal family of 4,000,000 a-year. By the budget of 1816 the income of the king was augmented to 30,000,000; but at the accession of Charles X. it was fixed at 25,000,000, whilst the allowances to the other branches of the royal family were increased to 7,000,000 a-year.

The royal household, as it was designated, included the following appointments:

Lord steward (grand maître)	140,000 fr.
One maître d'hôtel	40,000
Four chamberlains of the household	40,000
Nine stewards	72,000
Four under stewards	20,000
Four cooks	12,000
Chief purveyor of fish	3,000
Ten assistants	20,000
Wine	172,000
Kitchen consumption	585,000
Charcoal	65,000
Other expenses, 528,700	1,697,700 fr.
In the department of the king's chamberlain the expenses amounted to	988,000

There were, besides, thirteen palaces, each with a separate and expensive establishment; a large sum was annually paid in pensions; and, under the heads of music, the wardrobe, medical establishment, stables, the annual disbursements amounted to between two and three millions of francs. The support of the magnificent manufactory of porcelain at Sèvres, and the manufactory of tapestry at Gobelins in Paris, cost a large annual sum; the expenses connected with the *garde meuble,* where the crown jewels and royal insignia were kept, and the expense of coining medals, were considerable; the establishments for the support of the museum of painting and sculpture at Paris amounted to nearly 3,000,000 of francs a-year; an annual sum of 80,000 francs was allowed for the support of the Italian opera, and a sum of 45,000 francs for the encouragement of sacred music. After the revolution of 1830, the civil list of Louis Philippe was settled in 1832; and in fixing his allowances the Chamber had two matters to deal with; the royal domains, which had hitherto been appendages of the crown, and the money-grant of an annual allowance. The real property of the crown consisted of the Louvre; the Tuileries with their dependencies; the Elysée Bourbon; the chateaux, houses, buildings, manufactories, lands, meadows, farms, woods and forests, composing the domains of Versailles; Marly; Saint Cloud; Meudon; St Germain-en-Laye; Rambouillet; Compiegne; Fountainebleau; Strasbourg; Bordeaux; Pau, and others. Of these, the chateau of St Germain-en-Laye, and those of Strasbourg and Bordeaux, with several other items, amounting to L.626,000, were taken from the crown, and made applicable to the purposes of the state. The money allowance to the king was fixed at 12,000,000 of francs, or L.480,000 per annum; and the annual sum of 1,000,000 francs, or L.40,000, was allowed to the prince royal; and the allowances to the daughters were regulated by special laws.

Imperial government.

The imperial government of France is based on the sovereignty of the people and the great principles of 1789. The title of the chief of the state is Emperor of the French by the grace of God and the national will.[1] The crown is hereditary in the male line only, and by right of primogeniture. The members of the imperial family are alone eligible to the throne. The emperor exercises legislative power conjointly with the senate, the legislative body, and the council of state. The emperor is alone invested with the executive power, is completely independent of great state functionaries, and enjoys all the prerogatives pertaining to sovereign power. The members of the legislative body, as well as the councils general and of arrondissements, are said to be named by direct universal suffrage. The emperor is responsible to the French people. He is chief of the state; commands the land and sea forces; declares war; makes treaties of peace, alliance, and commerce; nominates to all employments; and alone initiates the laws. The ministers depend on the chief of the state. They, as well as all persons employed by the state, take an oath of obedience to the constitution and of fidelity to the emperor. The senate, whose number shall not exceed 150, is composed of cardinals, marshals, admirals, citizens, &c., named by the emperor. The dignity is for life.[2]

The constitution was modified by a *senatus-consulte* of 23d December 1852, by which it was decreed that the emperor has the right to pardon and to grant amnesties; and, when he thinks fit, to preside over the senate and council of state. It was also decreed that treaties of commerce have the force of law with respect to modifications of tariff therein stipulated. All works of public utility are ordered by the emperor. The ministerial departments under the Emperor Louis Napoleon amount to nine, namely, the minister of state and of the household of the emperor; the ministers of justice; of foreign affairs; of finance; of the interior; of war; of marine and the colonies; of agriculture, commerce, and public works; and of religion and public instruction.

Provincial government.

The system of provincial government throughout France is simple and effective. The kingdom is at present divided into 86 departments, with their capital towns. These departments are subdivided into 363 arrondissements or districts, 2847 cantons, and 36,835 communes. In each department the prefect is the chief magistrate, and, as well as the sub-prefect, is paid by government in proportion to the population and the extent of his jurisdiction, the salary varying from 40,000 to 10,000 francs a-year, whilst that of the sub-prefect is 4000 francs. The prefect of the department of the Seine has 100,000 francs a-year.

Councillors of prefecture.

To each prefecture and sub-prefecture are attached councillors (*conseillers de préfecture*, and *conseillers d'arrondissement*), who are likewise paid by government; and each has, besides, a general council, composed of the most opulent and respectable persons in the department, appointed by the king, which he convokes when necessary; and before this council he lays all public matters for its approbation. He is at the head of the police and of the national guard within his prefecture. It is his business to superintend all necessary repairs of public buildings, bridges, fortresses, walls of towns, &c.; to direct the cleaning and paving of streets and highroads; to inspect ports, quays, common sewers, poor-houses, &c. He superintends public libraries, museums, primary schools; fixes the price of bread; and grants passports. He is in correspondence with all the subordinate functionaries in his department, as well as with the minister of the interior, from whom he receives instructions to settle the question of all general taxes, and to provide for the public expenses of the department. He receives the produce of the *octroi*, a custom-duty levied on all articles of general consumption as they enter the town; and of all the rents of government entrepôts; of stalls and shambles in public markets; of slaughter-houses; of the proceeds from the sale of manure; as well as fines of police, and other imposts. One-tenth only of the octroi was under the monarchy paid to the government; and out of the remainder, and from other funds, was defrayed all the local expenses of police, lighting and cleaning streets. All the accounts are transmitted to the minister of the interior, who sends them to the *cour des comptes*. The functions of a sub-prefect are the same as those of a prefect. A *juge de paix* is at the head of every canton, who has also similar duties, and is, besides, employed in deciding civil suits to a certain amount. The mayors of the communes possess similar powers to those of the prefects of departments; and their receipts and expenses are provided for in a similar manner. In case of their requiring any extra funds for local expenses, they have the authority of the legislature to raise a contribution called *centimes communaux* from the inhabitants of the commune. To the office of mayor are attached municipal councillors, who have the same functions as the general council of the prefecture. The mayor may celebrate marriages, and at the *mairie* of the commune a marriage register is kept, as well as one of births and deaths; a notice of which the relatives of the parties are obliged to deposit at the office of the mayor, under a penalty of a fine in case of neglect. There is in every town a commissary of police, who is paid according to its population. Paris is divided into twelve *mairies*, called municipal arrondissements, in each of which is a mayor with two assistants. It is also distinguished from all other cities by having a prefect of police, who has very extensive functions, exercising all the multifarious duties of police within its precincts, having under his immediate orders the whole corps of police officers, the 48 commissaries of police belonging to Paris, and the corps of firemen.

Legion of Honour.

The most comprehensive, though the least ancient order, is that of the *Legion d'Honneur;* an order instituted by Bonaparte, and maintained on nearly the same plan by the Bourbons. The usual title to admission is the discharge of functions, either civil or military, with distinction; and, in time of war, the performance of an action of eclat. The gradations are, *chevaliers*, of whom the number is unlimited, and very great; *officiers*, who amount to no more than 2300; *commandeurs, grand officiers*, and *grand croix*. A member must serve several years as a chevalier before becoming an officer, and the same progressively through the other ranks. Admissions take place once, and frequently twice, a-year; a specific number being allotted to each great department of the public service, the military, the judicial, and the administrative.

The other orders under the monarchy were, that of St Louis, which is strictly military; that of St Michel, which dates from 1469, is limited to a hundred members, and is conferred as a recompense for distinction in science, literature, or the arts. Eminent professional men and artists, and the authors of discoveries of public utility, constitute the members of this order. The order *du St Esprit*, created in 1578, and of the very highest rank, comprised princes of the blood, prelates, and members of the order of St Michel; the whole being limited to the number of a hundred.

XIV. LAW, AND ADMINISTRATION OF JUSTICE.

In this great department France shows nothing of the backwardness apparent in her situation in many other respects, but is entitled to the particular attention of other nations, and of none more than our own. Law does not rest on tradition, nor is it necessary to study it in a never-ending accumulation of decisions. It is reduced to a compact and definite form, the result of a code formed recently, and with all the benefit of the application of the knowledge of an enlightened age to the principles of jurisprudence. Nothing could be more heterogeneous than the administration of justice in France before the revolution. The first stage of a process took place before judges appointed, not by the king, but by the *seigneur* or lord of the district. These judges had power to impose a fine, to decree a short imprisonment or other correctional punishment, and to give, in a civil suit, a decision subject to appeal. The *seneschals* and *baillis* ranked a degree higher, and were entitled to give a verdict in cases of importance, subject, however, to an appeal to one or other of the parliaments, of which there were in all thirteen in France; and which, very different from the parliaments with which we are familiar, were composed of judges and public officers of rank. The whole of this inharmonious mass was reduced into a simple and uniform system by the National Assembly, in 1791. Indeed, on the famous night of the 4th August 1789, seignoral and ecclesiastical judges may be said to have been buried in the ruins of feudal institutions, and on the 24th August 1790 a system entirely new, and founded on the territorial division of the country, was instituted. The seignoral judges were replaced by justices of the peace, and every district of importance (*arrondissement*) obtained its court, or *tribunal de première instance.* The higher courts were not added till afterwards, but the judges of every description were elected by the inhabitants of the province, a right which continued with them until the rule of Bonaparte.

---

[1] Preamble of the Constitution of 1852.

[2] *Moniteur Universel*, 15th January 1852.

Different codes.

But there remained for the National Assembly another and a much more laborious work. Each province had its peculiar code, or *coutoumier*, some founded on the Roman law, others on tradition and local custom, but the whole replete with ambiguity and discrepancy. To digest a complete body of law, that might suffice for the country at large, and supersede the provincial codes, was the labour of many years, and of a number of eminent lawyers. It was not completed until the beginning of the present century, when it was promulgated under Bonaparte, and gave to the jurisprudence and judicial constitution of France nearly the form they at present bear. This body of law consisted of five codes, entitled respectively, 1. *Code Civil;* 2. *Code de Procédure Civile;* 3. *Code de Commerce;* 4. *Code d'Instruction Criminelle;* 5. *Code Pénal.* To these have been added the *Code Forestier*, the *Loi relative à la Peche Fluviale*, and other laws too numerous to mention here. A *Code Administratif* (in which, however, some progress has been made since the work of Cormenin), a *Code Militaire*, and a *Code Maritime* are still wanting. The five codes were the result of the deliberations of the most eminent jurisconsults, in which Napoleon himself took part, and aided the men of science by his genius, his vast experience, and intuitive sagacity.

The *Code Civil*, the first and by far the most comprehensive of these divisions, defines the rights of persons in their various capacities of citizens, parents, sons, daughters, guardians, minors, married, unmarried. It next treats of property in its respective modes of acquisition and possession, as inheritances, marriage portions, sales, leases, loans, bonds, and mortgages.

The *Code de Procédure Civile* prescribes the manner of proceeding before the different courts of justice, beginning with the *juge de paix;* also the mode of carrying into effect sentences, whether for the payment of damages, the distraining of goods, or the imprisoning of the party condemned. It declares likewise the course to be followed in transactions distinct from those of the law courts; as in arbitration, taking possession of an inheritance, or a separation of property between man and wife.

The *Code de Commerce* begins by defining the duties of certain officers or commercial agents, such as sworn brokers and appraisers: it next treats of partnerships; of sales and purchases; of bills of exchange; of shipping, freight, and insurance; of temporary suspensions of payment, and bankruptcies.

The *Code d'Instruction Criminelle* explains the duties of all public officers connected with the judicial police, whether mayors, assistants of mayors (*adjoints*), *procureurs du roi*, *juges d'instruction*, &c. After prescribing the rules regarding evidence, it regulates the manner of appointing juries, and the questions which fall within their competency. Its further dispositions relate to the mode and nature of appeals, and to the very unpopular courts authorized to try state offences, termed *Cours Speciales* under Bonaparte, and *Cours Prévotales* under the Bourbons.

The *Code Pénal* describes the punishment awarded for offences in all the variety of gradation, from the penalties of the *police correctionnelle* to the severest sentence of the law. All offences are classed under two general heads; state offences, such as counterfeiting coin, resisting police officers, sedition, rebellion; and offences against individuals, as calumny, false evidence, manslaughter, murder.

These codes, the first attempt to reduce the laws of a great nation to the compass of a volume, consist of a number of sections and short paragraphs, each paragraph marked by a number, as a means of reference. The style is as concise as is compatible with clearness. The arrangement is minute and elaborate. The whole, together with the *Code Forestier* and the *Code de la Pèche Fluviale*, the work of the restoration, are sold for a few shillings, in the shape of an octavo or of two duodecimo volumes; and copies of it are in the possession, not only of all judges, pleaders, and attorneys, but of agents, merchants, and persons in business generally, who, without being enabled by it to dispense with the aid of lawyers in a suit, find in it a variety of useful explanations relative to questions of frequent occurrence in their respective occupations.

Juges de Paix.

The *juges de paix* are very numerous, there being one for each canton, and consequently nearly three thousand in the kingdom. They never are, as in England, clergymen, and seldom country gentlemen, but persons acquainted with law, and in circumstances which make the salary, small as it is (from L.30 to L.40), an acceptable return for a portion of their time. They are sometimes provincial attorneys, or *avocats* retired from business. The *juge de paix* is authorized to pronounce finally under fifty francs, or L.2; and in questions of greater amount up to a hundred francs, to give a decision subject to appeal. He takes cognizance likewise of disputes about tenants' repairs, servants' wages, and the displacing of the landmarks of property. No action can be brought before a court of justice in France until the plaintiff has summoned his adversary before a *juge de paix*, with an amicable intent (*cité en conciliation*), and received from the *juge* a *procès verbal*, showing that the difference could not be adjusted. The number of *juges de paix* is about 3000, and their salaries amount to about two and a half millions of francs.

Primary courts.

Of the *Primary Courts* there is one for every arrondissement, making above three hundred and sixty for the whole of France. Each is composed of three or four members, of two or three *suppléans*, or assistant members, and of a *procureur du roi* acting on the part of the crown. In populous districts, *cours première instance* comprehend six, seven, eight, or more members, and are divided into two or three chambers. They are chiefly occupied with questions of civil law, and hold, in the extent of their jurisdiction, a medium between the limits of the *juge de paix* and the large powers of the *cour royale;* their decisions being final wherever the income from a property does not exceed forty shillings, or the principal forty pounds, but subject in greater matters to an appeal to the *cour royale.* The members of these inferior courts are named, like other judges, by the crown, and hold their places for life; the salary of each is only L.80 a-year; their number throughout all France, including *suppléans procureurs-genéraux*, is about 4300, and their salaries, in round numbers, amount to 6,000,000 francs.

A section of the *Tribunal de Première Instance* is appropriated to the trial of offences, under the name of *Tribunal de Police Correctionelle;* and here the English reader must be careful to distinguish between judicial and government police; the former having no reference to state offences, such as libel or treason, but comprehending a very numerous list of another kind, viz. all offences which do not amount to crimes, or subject the offender to a punishment *afflictif ou infamant.* These offences, when slight, are called *contravensions de police*, and are brought before a *juge de paix*, or the mayor of the commune; when of a graver stamp, and requiring a punishment exceeding five days' imprisonment, or a fine of fifteen francs, they are brought before the court now mentioned, whose sentences, in point of imprisonment, may extend to the term of five years. The trespasses brought before a justice of the peace or mayor are such as damaging standing corn, driving incautiously in the highway, endangering a neighbour's property by neglecting repairs. The offences referred to the *Tribunal Correctionnel* are such as assault and battery, swindling, privately stealing, using false weights or measures, &c.

Cours royales.

We now come to the higher courts of justice, which equal in jurisdiction our courts in Westminster Hall and on the circuit, but with the material distinction, that in France the civil courts are always stationary. The *Cours Royales*, in number twenty-seven, are attached to the chief provincial towns throughout the kingdom. They are all formed on the same model, and possessed of equal power, though differing materially in extent of business and number of members. The number of the latter depends on the population of the tract of country (generally three departments) subject to the jurisdiction of the court. In a populous quarter, like Normandy, a *cour royale* comprehends twenty, twenty-five, or even thirty judges, and is divided into three or four chambers, of which one performs the duty of an English grand jury, in deciding on the bills of indictment (*mises en accusation*); another is for the trial of offences (*police correctionnelle*); and a third, with perhaps a fourth, is for civil suits. These courts are often called *Cours d'Appel*, as all the cases which come before them must have been previously tried by an inferior court. The collective number of judges in these higher courts is not short of twelve hundred; an aggregate hardly credible to an English reader, and which would prove a very serious charge on the public purse, were not their salaries very moderate, viz. from L.100 to L.300 a-year, according to the population of the town where the court is held. In the financial pressure of 1816 and 1817, a reduction of this numerous body was much called for; but no diminution was made in the number of the courts, whatever gradual decrease may be allowed to take place in the members from decease or retirement. The salaries of these 1200 magistrates do not annually exceed five millions of francs.

Paris does not, like London and Edinburgh, absorb almost all the civil business of the country. It has, it is true, a *cour royale* on a large scale (five chambers and fifty judges), but confined in its jurisdiction to the metropolis and the seven adjacent departments. There is a *procureur du roi* for every *tribunal de première instance*, and a *procureur general* for every *cour d'appel*.

Assize courts.

The assize courts take cognisance exclusively of criminal cases; that is, of the crimes or serious offences referred to them by the *cours royales*. They consist, since 1837, in the departments where a court of appeal is situated, of three judges, members of the *cours royales*, but never belonging to the section that finds the indictments. The grand accompaniment of a French assize court is a jury, which, as in England, consists of twelve members, and decides on the facts of the case, leaving the application of the law to the judges. Complete unanimity was at no time necessary in a French jury. At first a majority of ten to two was required; but this was subsequently altered, in 1835, to a simple majority, with the qualification that, in case of condemnation by only two voices (seven to five), the verdict should be re-considered by the judges, and the party acquitted, if, on taking judges and jurymen collectively, there was a majority in his favour. The assizes are the only courts that are not stationary. They are generally held in the chief town of a department once in three months. The costs of suit are exactly defined by a printed *tarif*; and it is a rule in criminal as in civil cases, that the party condemned is liable in all expenses.

Cours spéciales.

The *special courts* were constituted out of the usual course for the trial of state offences. The *cours spéciales* were appointed by Bonaparte, the *prévotales* during the period of political effervescence (fortunately short-lived) which succeeded the second entry of the king, and the misfortunes brought on the nation by Bonaparte's return frm Elba. In both cases the courts were considered as under the influence of government, and were of course obnoxious to the enlightened part of the public. The *prévotal courts* established in 1815 were abolished in 1818.

Tribunaux de commerce.

The name of *tribunal*, or court, is given in France to a committee of five merchants, or leading tradesmen, appointed by the mercantile body in every town of considerable business or population. Their competency extends to all disputes occurring in mercantile business, and falling within the provisions of the *code de commerce*. Their decisions are founded on that code, and on the customs of merchants. They are final in all cases below L.40. The presence of three members is necessary to form a court. The duty is performed gratuitously. There are about 220 special tribunals of commerce in France. The number of commercial affairs decided between 1846 and 1850 amounted to 201,207. The tribunal of commerce of the Seine determines about 50,000 commercial causes a-year. Lyon, in round numbers, 10,000; Rouen, 5000; Marseilles, 5000; Bordeaux, 3500.

Cour de cassation.

The *court of cassation*, the highest in the kingdom, is held at Paris, and is composed of three chambers, each of fifteen members and a president, making, with the *premier president*, a *procureur-général*, and six *avocats-généraux*, a total of fifty-two. The three chambers are called *chambre des requêtes, chambre de cassation civile*, and *chambre de cassation criminelle*. Its province is to decide definitively in all appeals from the decrees of the *cours royales*; investigating not the facts of the case, but the forms of law, and ordering, wherever these have been infringed or deviated from, a new trial before another *cour royale*. This revision takes place in criminal as well as in civil cases. The royal court chosen for the new trial is generally, for the convenience of the parties, the nearest in situation to the other. The *cour de cassation* has farther powers, and of the highest kind. It determines all differences as to jurisdiction between one court and another, and exercises a control over every court in the kingdom. It has power to call the judges to account before the minister of justice, and even to suspend them from their functions; acting thus as a high tribunal for the maintenance of the established order of judicature.

Ministry of justice.

The minister bearing the title of keeper of the seals and minister of justice may be compared to the chancellor of England, though his patronage is much less extensive, and his functions much more suitable to the station of minister. He rarely acts as a judge, but exercises a general superintendence over the judicial body. He is the medium between the head of the state and the courts of justice, in the same way as the minister of the home department in regard to the civil authorities. The expenses of the judicial body fall under his cognizance. The *procureurs-généraux* and *procureurs du roi* throughout the kingdom address their correspondence to him; and it is his province to report to the king on the alleviation of punishment, or pardons; in short, on all disputed points, whether of legislation or administration.

Juries.

Juries were introduced into France soon after the first revolution in 1789, and confined at first to criminal trials. After the revolution of 1830 all cases of libels were tried in the courts of assize by a jury. During several years there were in France grand juries constituted as in England; but under Bonaparte their functions were transferred to the *cours royales*, on the plea that none but judges could be made to understand the difference between bringing to trial and bringing to punishment; and that the consequence frequently was a discharge, when a true bill ought to have been found.

State of crime.

One of the chief improvements made by the French National Assembly was a general mitigation of the penal code, or rather the substitution of punishments likely to be enforced, for others of such severity as in general to put their application out of the question. Stealing privately in a dwelling-house was formerly punishable in France by the rack and death; an extreme which prevented respectable persons from bringing delinquents before a court, and thus tended to the increase of crime.

There still exists in France the singular practice of parties engaged in a law-suit visiting the judges in private; a practice originating in an age when suitors thought a personal interview the only effectual mode of explaining their case, and continued in more enlightened times from that over-complaisance which is the groundwork of several of the defects of the national character. Such interviews are little else than an exchange of compliments; nor have the judges ever been charged with acting under the influence of such *ex parte* statements.

The salaries of French judges must appear insignificant to an English reader; but there are in that country many men of small patrimony and good education who are disinclined to the exercise of trade or professions, but attach much importance to government employment; moreover, the functions of judges and of public officers in France engross much less time than in England.

The law style of the French is much more brief than ours; their deeds, such as leases, mortgages, and sales, being generally contained in a very few pages, and free from obscure or antiquated phraseology.

Prior to the year 1825 there existed in France no authentic documents respecting the administration of criminal justice in France; and in order to know the nature and the number of the crimes committed during the preceding years, it would have been necessary to look back into the records of every prefecture throughout the country; and such a work, besides its extreme difficulty, would have been too incomplete to be of any utility.[1] Within the last quarter of a century, however, the statistics of crime and of criminal justice in France have been made familiar to the world by a series of official reports, in which the details of the criminal calendars throughout France are brought together and perspicuously arranged. In these reports, the crimes and offences brought under consideration are divided into three great branches: the first relating to such crimes as are tried before the courts of assize, with the assistance of a jury: the second to offences of minor importance, decided by correctional tribunals; and the third to such as are disposed of by the ordinary magistrates of police. Of 6962 persons tried in the courts of assize in the year 1830, 3910 were for crimes against property, and 1158 for crimes against the person. The proportion between the number of persons judicially accused of offences, and the general population of the kingdom was, in 1829, as one in 4321; and in 1830, as one in 4576. Of the 6962 brought to trial in 1830, 5608 were men, and 1354 were women. There were 5440 accusations brought before the courts of assize in 1853, affecting 7317 persons. Of these 2403 were for crimes against the person, and 4914 for crimes against property. If the number of accused persons in 1853 be compared with those of the two preceding years, a gradual diminution appears in the number accused of crimes against the person. In 1851 the number accused was 2773. In 1852 the number was reduced to 2487, and in 1853 to 2403. The number of crimes against property has on the contrary increased from year to year. From 4298 in 1851 the number increased to 4609 in 1852, and to 4914 in 1853.

---

[1] See *Essai sur la Statistique Morale de la France*, par. A. M. Guerry, p. 5.

The accusations, in the mean, from 1831 to 1835, were 7466; for the next 5 years, to 1840, 7885; and from 1840 to 1845, 7209. Of 7195 accused, 2031 were for crimes against the person, and 5164 for crimes against property, and 5898 were men, 1297 women. The proportion of persons criminally accused is generally 1 in 4500; the mean for 19 years being 1 to 4445. On 5000 condemned in each of four years, the following were the sentences:—

Death	50	42	50	51
Perpetual hard labour	178	174	196	209
Limited term	930	918	929	961
Seclusion	875	858	905	827
Banishment	1	0	0	0
Imprisonment	11	0	0	0
Civil degradation	1	1	1	0
Correctional penalties	2946	2682	2777	2825
Correctional detention	24	27	26	29
	5016	4702	4884	4902

Of 100 accused, about 30 are acquitted. Most of the accused are illiterate, the women especially. Before 1840 there were 56 in 100 who could not read; after 1844 the number fell to 52. Between 1846 and 1850 crime augmented considerably, especially crimes of a heinous character.

The public peace is maintained by an armed police, or *gendarmerie*, partly on foot and partly mounted; and in all emergencies, when this force is found insufficient for the preservation or execution of the laws, the national guards and troops of the line may be called in to assist, being, however, subject to the orders of the police.

In France, the prisons, which constitute an important department of the criminal police, are under the special direction of the minister of the interior. His delegates are the prefects; and the jailors or governors of the prisons are called directors. In every city containing a prison there is an inspector-general, who attends to the proper distribution of the provisions, and sees that they are of good quality; he daily visits the prisons, listens to the complaints of the prisoners, and attends to their comforts. The departmental prisons are for the confinement of debtors, for persons to be brought to trial for crimes, and for those who are condemned to imprisonment for a shorter period than a year. The annual expense of these prisons makes part of the budget of the minister of the interior. The other prisons (*maisons centrales*) are nineteen, for the confinement of prisoners whose sentence is for a longer term than a year.

It is estimated that during the last thirty years the mere building of prisons in France has cost more than 60,000,000 francs, and that the maintenance of these prisons has cost annually 12,000,000 fr., including the support of 100,000 *détenus* of all categories of crime. More than 4,000,000 francs has been annually paid for the expenses of prosecutions, and a like sum for the expense of police and surveillance. Labour was carried on in the prisons of France antecedently to the revolution of 1848, though several complaints were made of the rivalry thereby encouraged with legitimate trade. For instance, the Chamber of Commerce of Troyes complained to the minister of the interior of the ruinous rivalry produced by the prison labour of the *Maison Centrale of Clairvaux*, where 2000 *détenus* were confined, and chiefly employed in the fabrication of *bonneterie*. In the *Maison Centrale* of Melun a great manufactory of ironmongery was established. In the penitentiary of St Germain they made hats and horn buttons; and a printing-office also was established, where, among other things, the *Moniteur* was cheaply reprinted. In 1848 the provisional government suspended prison labour, but this decree had no other effect than to throw the prison into disorder. By a law of the 9th January 1849, labour in prisons was under certain restrictions renewed. The average price of a day's work is fivepence. The labour of 11,865 men in the 21 *maisons centrales* of France has a value of 1,749,000 fr., that of 3457 women 400,000 fr., forming a total of 2,100,000 fr., a small sum when compared with the products of free labour. The produce of prison labour is thus divided:—Those condemned to *travauxforces* receive 3-10ths, the reclusionnaires 4-10ths, the correctionnels 5-10ths.

FRENCH WEIGHTS AND MEASURES.

The weights and measures of France were reduced, as is well known, to a very simple and uniform scale soon after the first revolution; but there has been much difficulty in accustoming the inhabitants, particularly in country districts, to the adoption of the new system, which unluckily preserved none of the names with which they were familiar. In 1812 a kind of compromise took place, government sanctioning the retention of the old names, such as pounds, ounces, ells, and bushels; but requiring that their contents should be calculated by a reference to the new standard. It is accordingly on this footing that business is now transacted in France. The new weights and measures are in general larger by a fraction than the old, and the use of the latter is prohibited by law.

The fundamental standard adopted in France for the metrical system of weights and measures, is a quadrant of the meridian; that is to say, the distance from the equator to the north pole. This quadrant is divided into ten millions of equal parts, and one of these parts or divisions is called a MÈTRE, which is adopted as the unit of length; and from it by decimal multiplication and division all the other measures are derived.

The length of this quadrant was ascertained by MM. Delambre and Méchain, by measuring an arc of the meridian between the parallels of Dunkirk and Barcelona, and has been found to contain 5,130,740 French toises, or 32,808,992 English feet. This number divided by ten millions gives 3·2808992 English feet, or 39·37079 English inches very nearly, for the true length of the French mètre.

In order to express the decimal proportions, the following vocabulary of names has been adopted:—

For multipliers the prefix DÉCA means 10 times.
... HECTO ... 100 times.
... KILO ... 1,000 times.
... MYRIA ... 10,000 times.
For divisors the prefix DÉCI expresses $\frac{1}{10}$th part.
... CENTI ... $\frac{1}{100}$th part.
... MILLI ... $\frac{1}{1000}$th part.

It may assist the memory to observe that the prefixes for multiplying are Greek, and those for dividing Latin; thus, décamètre means 10 mètres, and décimètre $\frac{1}{10}$th of a mètre; hectomètre means 100 mètres, and centimètre $\frac{1}{100}$th of a mètre; kilomètre means 1000 mètres, and millimètre $\frac{1}{1000}$th of a mètre. The mètre (as before stated) is the element or prime unit of long measure, and is equal to 39·37079 English inches.

The ARE, which is a square *décamètre* (or 100 square metres), is the elemental unit of square or superficial measure. It is equal to 119·6033 square yards, or very nearly $\frac{2}{81}$ parts of an acre.

The STÈRE, which is a cubic mètre, is the elemental unit of solid measure, and equal to 35·3166 cubic feet English, or nearly $35\frac{1}{3}$ cubic feet.

The LITRE, which is the cubic *décimètre*, is the elemental unit of all liquid measures, and of all other measures of capacity. It is equal to 61·02705 cubic inches, or is very nearly $\frac{11}{50}$ths or $\frac{22}{100}$ths of an imperial gallon.

Lastly, the GRAMME, which is the weight of a cubic centimètre of distilled water at its temperature of greatest condensation, is the elemental unit of all weights, and is equal to 15·4325 grains troy, or $\frac{13}{23}$ of an avoirdupois dram nearly.

Tables of French Weights and Measures, with their values in the English Imperial Standards.

LINEAL MEASURE.

	Inches.		
Millimètre =	·03937079

Kilogramme =	15432·5	= 2·2047 lbs. av.
Miriagramme =	154325·	= 22·047 lbs. av.

The following are some near approximations to the values of the weights and measures of most frequent occurrence.

MÈTRE about.... 1 yard 3 inches.
DÉCAMÈTRE..... 11 yards.
HECTOMÈTRE... $\frac{1}{16}$ mile.
KILOMÈTRE..... $\frac{5}{8}$ or more nearly $\frac{18}{29}$ mile.

One of the old measures frequently used, the toise, is = 2 yards 5 inches.

ARE about........ $\frac{1}{40}$ acre.
DÉCARE.......... $\frac{1}{4}$ acre, or 1 rood.
HECTARE......... $2\frac{1}{2}$ acres.

DÉCISTÈRE...... $3\frac{1}{2}$ cubic feet.
STÈRE........... $1\frac{2}{3}$ cubic yards.
DECASTÈRE...... $13\frac{1}{10}$ cubic yards.

LITRE about..... $\frac{1}{5}$ or $\frac{11}{50}$ gallon.
DÉCALITRE...... $2\frac{1}{5}$ gallons.
HECTOLITRE.... 22 gallons, or $2\frac{3}{4}$ bushels.
MYRIALITRE.... $3\frac{1}{2}$ quarters.

GRAMME......... $\frac{5}{9}$ dram avoird.
DÉCAGRAMME... $\frac{1}{3}$ oz. avoird.
HECTOGRAMME. $3\frac{1}{2}$ oz.
KILOGRAMME... $2\frac{1}{5}$ lbs.
QUINTAL, or 100 Kilogrammes.. } is $3\frac{1}{2}$ lbs. less than 2 cwt.

FRENCH MONEY.

The French monetary *unit of value* is the FRANC, which in the gold coinage of 20 and 40 franc pieces is equal in value to 9·525 pence sterling, and in the silver coinage of francs and five-franc pieces is = 9·705 pence; but the common rate of exchange is twenty-five francs for one sovereign, which gives the value of a franc = $9\frac{3}{5}$ pence sterling.

Centime............... = ·096d. = ·384 farth. = $\frac{2}{5}$ farth. nearly.
Décime................ = ·96d. = 3·84 farth. = $3\frac{21}{25}$ farth.
FRANC................. = 9·6d. = $9\frac{3}{5}$ pence.
Five-france piece... = 4 shillings.
Napoléon or 20-franc piece...... } = 16 shillings.

In reducing French money to English, from any number of francs subtract their fifth part, and the remainder will be their value in shillings. Or multiply the francs by four, point off the two right hand figures of the product for decimals, and the result will be their value in pounds and decimals of a pound sterling. (A. V. K.)

Isle of France, or Mauritius. See Mauritius.

FRANCHE COMTÉ, an old province of France, now divided into the departments of Haute Saône, Doubs, and Jura. Its capital was Besançon.

FRANCHISE, in *Law*, is used as synonymous with *liberty*, and is defined "a royal privilege, or branch of the king's prerogative, subsisting in the hands of a subject." Being thus derived from the crown, a franchise must arise from the king's grant; or in some cases it may be held by prescription, which presupposes a grant. The kinds of franchise are almost infinite.

For an account of the nature of the *elective franchise*, see Parliament.

Franchise is also used to denote an asylum or sanctuary, where persons are secure from arrest. One of the most remarkable capitulars made by Charlemagne in his palace of Heristal, in 779, was that relating to the franchises of churches. The right of franchise was held so sacred that even the less rigidly righteous kings scrupulously observed it; but in course of time it was carried to such excess, that Charlemagne reduced it, by forbidding the conveying of provisions to criminals who had fled for protection to these sanctuaries.

FRANCIS, Philip, an English versifier and dramatic writer, but more distinguished for his translations of classical authors than for his original compositions. His father was dean of Lismore, and rector of St Mary's, Dublin, whence he is said to have been ejected at the Revolution on account of his principles. The son received his theological education at Dublin; but, after taking orders, he came over to England, and settled at Esher in Surrey, where he opened a school. He obtained the degree of LL.D., and was afterwards presented to the rectory of Barrow, in Suffolk, and made chaplain of Chelsea hospital. He wrote two tragedies, *Eugenia*, 1752, and *Constantia*, 1754, neither of which, however, met with a favourable reception at the time of its appearance, and both have now fallen into oblivion. But his translation of Horace with notes was completely successful, and has been often reprinted. In 1757 he published a translation of the orations of Demosthenes and Æschines, in two vols. 4to. Dr Francis was also a political writer of some note, and was said to have been employed by government. He died at Bath in 1773.

Francis, *Sir Philip*, a distinguished politician, and the supposed author of the *Letters of Junius*, was the only son of the preceding Dr Francis. He was born at Dublin in 1740; received the chief part of his education at St Paul's School, London; and when only sixteen years of age was placed as a clerk in the Secretary of State's office by Mr Henry Fox, afterwards Lord Holland, in whose family Dr Francis had been tutor. When Mr Pitt (Lord Chatham) succeeded as Secretary of State, he continued young Francis in the office, and seems to have noticed his precocious talents for public business. More than a quarter of a century afterwards Francis gracefully acknowledged this in the House of Commons. "I hope," he said, "it will not appear improper in me to say that in the early part of my life I had the good fortune to hold a place, very inconsiderable in itself, but immediately under the late Earl of Chatham. He descended from his station to take notice of mine, and he honoured me with repeated marks of his favour and protection. How warmly, in return, I was attached to his person, and how I have been grateful to his memory, those who know me know. I admired him as a great, illustrious, faulty human being, whose character, like all the noblest works of human composition, should be determined by its excellencies, not by its defects. . . . But he is dead, and has left nothing in this world that resembles him." The last allusion is, of course, an insidious, Junius-like blow at Chatham's son, the second William Pitt. Before he had come of age, Philip Francis was secretary to General Bligh in the expedition against Cherbourg, and also secretary to the Earl of Kinnoul on a special embassy to Lisbon. In 1763 he was appointed to a principal clerkship in the War Office, with a salary of about L.400 per annum. He held his post during the period in which the Letters of Junius appeared in the *Public Advertiser* until the year 1772, when a Mr Chamier was appointed over him as Deputy Secretary at War. In consequence of this slight, Francis resigned his clerkship, indignant at Lord Barrington, the head of the War Office, and full of bitterness and contempt towards the new deputy. It will be recollected how keenly Junius attacks Lord Barrington, and how he descends from the usual elevation of his style to pour out low and scurrilous invectives against Chamier. Of all the subordinate points of the evidence connecting Francis with Junius, this affair of Chamier appears to us one of the most convincing. Junius claimed to be a man of rank, above a common bribe; but the spirit of the subordinate official—the disappointed War-Office clerk—breathes through all his references to this subject, and destroys his factitious dignity. Having left the War Office, Francis went abroad, and travelled for about a year in France and Italy. There was at the same time a cessation in the correspondence of Junius with his publisher Woodfall, but he addressed him again in January 1773, and Francis had then returned from his continental tour. In June of the same year Francis received from Lord North what must be considered a splendid appointment. He was, *on the recommendation of Lord Barrington*, made one of the Supreme Council of Calcutta, constituted by Act of Parliament, with a salary of L.10,000 per annum each, for the purpose of co-operating in the government of India. The chief of this new board was Warren Hastings, styled Governor-General, and the councillors were Mr Barwell (an able servant of the Company in India), General Clavering, Colonel Monson, and Philip Francis. The advancement of Francis from a clerkship in the War Office, and especially through the instrumentality of Lord Barrington, who formerly thwarted his rise in the public service, to a post of such high trust and emolument, has led to a belief that the ministry had somehow become aware of the authorship of Junius' Letters, and by this important foreign appointment effectually removed and silenced Francis. His talents, however, justified the confidence placed in him, and Lord Barrington may have been anxious to repair his former injustice. It is certain that no further letters from the pen of Junius appeared after Francis had sailed for India. His seat at the council-board of Calcutta was not favourable to his peace or happiness. From the moment of their arrival Warren Hastings disliked his new coadjutors. He received them with less than the customary etiquette, and was jealous of the power they came to divide with him. Francis, on the other hand, was proud, unbending, and irascible; and the quarrel rose to such a pitch, that while the councillor pretty plainly accused his chief of deliberate fraud, extortion, and cruelty, the latter stated in a minute delivered to the council-board that "he judged of the public conduct of Mr Francis by his experience of his private, which he had found to be void of truth and honour." A duel was the consequence, and Francis received a dangerous wound, the ball striking him below the shoulder, and passing out at the lower part of the body. He recovered; but finding that Hastings was triumphant in his Indian policy, and supported by public favour, as well as by a majority of the board, he returned to England in the year 1781. A man of strong passions and implacable in his resentments (which he identified with public duty and patriotism), Francis now devoted himself to the impeachment of Hastings, giving his powerful assistance to Burke, Fox, and the other Whig leaders. He was proposed as one of the managers of the public im-

Francis.

Franciscans || Franeker.

peachment (having been returned to parliament for the borough of Yarmouth), but his appointment was negatived on what were sufficient grounds—his duel with Hastings, and the avowed enmity that had so long subsisted between them. The result is well known. The trial of Hastings fixed the attention of Europe, and has been drawn in imperishable colours by Mr Macaulay in the most popular and magnificent of his historical pictures. Francis was the mainspring of the whole. He supplied the information which Burke and Sheridan expanded into eloquent orations and burning invective; and these services, as well as his general support of Whig measures, rendered him conspicuous among the public men of his day. He was a forcible and impressive parliamentary speaker, but wanted fluency, and this was probably the cause why he so often resorted to the press, with letters and pamphlets on political questions. On the accession of the Whig party to power in 1806 Mr Francis was invested with the Order of the Bath. He died in December 1818.

A full statement of the claims of Sir Philip Francis to be considered the author of Junius' Letters would require greater space than the nature of a work like the present would permit. They rest upon circumstantial evidence—on the correspondence of dates and incidents in the life of Sir Philip with the dates and incidents in the publication of the letters—in the agreement of style, sentiment, and literary ability—and in the similarity of handwriting, peculiarities of spelling and punctuation, and other minute resemblances. Of all the candidates for the Junius' laurel, Francis alone seems to have possessed the requisite intellectual power and tastes. None of his acknowledged productions are so highly finished, but they are racy and vigorous in style, and abound in vivid illustration, and in interesting reminiscences of his early great contemporaries, and past events. He inherited all the friendships and antipathies of Junius, indulged in strong personal animadversions, and despised the cold infusions of prudence and moderation in the discussion of public questions. We have seen Francis's practical acquaintance with the War-Office, and his resentment at the appointment of Mr Chamier, both so conspicuous in Junius. He owed his first introduction to the public service to the family of Lord Holland, and Junius uniformly spares Lord Holland, even when heavy charges of malversation of the public money impended over him. He frequently heard Lord Chatham speak, took notes of his speeches, and gave them to the printer; and Junius gives extracts from speeches of Lord Chatham closely resembling those of Francis. During the publication of the letters, Francis was exactly in the situation to know all the interior movements of the different departments; and he is known to have been in close intimacy with Calcraft, the army agent, a political jobber, who furnished information to Chatham and the Grenvilles. Dr Francis, the father of Sir Philip, may have unconsciously contributed details, for he moved in the higher political circles, was patronized by the Holland family, and was the favourite chaplain of Lord Chesterfield. When the first of the undoubted letters by Junius (signed "Atticus") appeared, Philip Francis was in his twenty-sixth year, an early age certainly for so active a plotter and politician, but he had then been ten years in public employment, had known Chatham and other statesmen, and was all his life restless and ambitious of personal and literary distinction. He was twenty-nine before the signature of Junius was adopted. Late in life—we believe when a septuagenarian—Sir Philip Francis entered into a second marriage; and this lady, his widow, has adduced almost direct testimony to support his right to the name of Junius. In a communication published by Lord Campbell in his *Lives of the Chancellors*, Lady Francis states that she never entertained a doubt that Sir Philip was the author of the letters, though he never avowed himself more than by saying he knew what her opinion was, and never contradicting it. "His first gift after our marriage," adds Lady Francis, "was an edition of Junius, which he bid be take to my room, and not let it be seen, or speak on the subject; and his posthumous present, which his son found in his bureau, was *Junius Identified*, sealed up and directed to me." This work, *Junius Identified*, was written in 1816, to prove that Sir Philip Francis was Junius; and the evidence it contains has been pronounced satisfactory by the ablest of our critical judges—by Mackintosh, Brougham, Macaulay, Lord Mahon, and Lord Campbell. According to Lady Francis, Lord Chatham gave assistance after the éclat of Junius's controversy with Sir William Draper, but probably without knowing that Francis was the writer. In Calcraft, however, there was a ready and safe medium of communication. Since the publication of the *Grenville Papers* it seems pretty clear that Junius received hints from Lord Temple and his brother, George Grenville, whose patronage he had in a private letter solicited, stating that he would avow himself when Grenville became prime minister. (See GRENVILLE.) In the case of Sir William Draper, a difficulty has lately been removed by Mr Macaulay. To the military knight Junius put a direct and searching question—"When you receive your half-pay do you, or do you not, take a solemn oath, or sign a declaration, upon your honour, to the following effect—*That you do not actually hold any place of profit, civil or military?*" Sir William answered decidedly in the negative: he took no such oath, nor made any such declaration; and this not only gave him a great advantage over his assailant, but seemed to prove that Junius was not so well acquainted with the forms of the War-Office as Philip Francis must of necessity have been. But how stands the fact? In the English War-Office such a declaration was necessary, but Draper drew his half-pay from the Irish establishment, and the declaration was not required from him. Francis relied on his official knowledge, and did not consider that there might be a difference between the practice at Westminster and the practice at Dublin. On the whole we may conclude that a clearer case of circumstantial evidence has rarely been submitted than that which identifies Sir Philip Francis with Junius. That he made no open avowal himself is easily accounted for. We believe he could not have done it without implicating others. The letters, by their malevolence and injustice, were as injurious to his moral reputation as they were honourable to his literary talents. He had received great benefits from some of the persons he had libelled, and he mixed in society with the immediate descendants of some of the powerful families he had wantonly and malignantly aspersed. The letters contain few great constitutional principles or maxims, like the writings of Burke, and they defend some political measures and opinions (such as the American Stamp Act, and the retention of the rotten boroughs in our parliamentary representation) which the mature judgment of Francis must have condemned. In his own family Sir Philip seems to have all but dropt the veil. He evidently had a lingering desire for posthumous fame when he made the partial disclosures to his wife. The letters had cost him great labour. They were polished to the utmost brilliancy, and inflicted deep and envenomed wounds, with matchless dexterity and skill. His shafts had been aimed at the highest quarters, and invaded the most sacred and private recesses of life—a degree of daring which must be considered as audacity rather than courage, for the mask of invisibility was strictly and marvellously preserved. There were also noble sentiments and bursts of fine feeling scattered through the letters, which seemed to betoken a great and generous nature warped by passion, arrogance, and secret motives of faction. These, however, bear but a small proportion to the rash assumptions, the bold invective and scandal which, aided by all the graces of style—unrivalled sarcasm, terse expression, and happy imagery—raised Junius into almost unparalleled popularity, and bid fair to continue him, now that the mystery and immediate interest are dispelled, as a great and unique English classic. (R. C—S.)

FRANCISCANS, the followers of the rule of St Francis, constituting one of the four orders of mendicant friars. In the beginning of the fourteenth century the whole Franciscan order was divided into two parties; one of which embraced the severe discipline and absolute poverty of St Francis, and were called *spirituals;* and the other, who insisted on mitigating the austere injunctions of their founder, were denominated *brethren of the community.*

The Life of St Francis was written by Bonaventura, and has often been published. But of all the writers who have given an account of this famous enthusiast, the most minute is Lucas Wadding, in his *Annales Minorum.* This work has been much enlarged by subsequent writers, the edition of 1731 and onwards extending to 18 vols. folio. See also the Life of St Francis in Sir James Stephens' *Ecclesiastical Biographies.* See FRATRICELLI.

FRANCONIA, German *Franken*, a circle of the old German empire, lay between Upper Saxony, Bohemia, Bavaria, Swabia, and the Upper Rhine, and had an area of about 10,400 square miles, with about 1,500,000 inhabitants. It is now almost entirely comprised in Bavaria, and gives name to three circles of that kingdom. The soil of Franconia is reckoned among the most fertile in Germany.

FRANEKER, a town of Holland, province of Friesland, 10 miles W. of Leeuwarden, on the canal between that town and Haarlingen. A university was founded here in 1585, but was converted into an athenæum in 1815. There are several other schools, a public library, and a botanic garden. The chief manufactures are silk and woollen goods, and tiles. Pop. (1850) 5288.

FRANK, the name by which the Turks, Greeks, Arabs, &c., designate a Christian. It probably originated during the crusades, in which the French (descendants of the German Franks) particularly distinguished themselves. Europe itself, too, was named *Frankistan*, or the country of the Franks.

The Frank language, *Lingua Franca*, is a jargon which is spoken in the Levant, as the common medium of communication between Europeans and the inhabitants of the East. Its chief ingredient is Italian, and it probably originated during the crusades, which brought so many different nations together.

Frank-Almoigne (*libera eleemosyna*), or free alms, a tenure of a spiritual nature, by which a religious corporation, aggregate or sole, holds lands of the donor granted to them and their successors for ever. The service which they were bound to render for these lands was not definitively stated; but only in general they were to pray for the souls of the donor and his heirs, dead or alive. Hence they did no fealty, which is incident to all other services, because this religious service was of a higher and more exalted nature. This is the tenure by which almost all the ancient monasteries and religious houses held their lands, and by which also the parochial clergy, and many ecclesiastical and eleemosynary foundations hold them at this day; but the nature of the service was altered at the Reformation, and made conformable to the reformed doctrines of the Church of England. It was an old Saxon tenure; and continued under the Norman domination, from the veneration paid to religious institutions. This was also the reason why tenants in frank-almoigne were exempted from all other services except the *trinoda necessitas* of repairing the highways, building castles, and repelling invasions, just as the Druids, amongst the ancient Britons, had *omnium rerum immunitatem*. And even at present this is a tenure of a very different nature from all others, being not in the least feudal, but merely spiritual; for, if the service be neglected, the law gives no remedy by distress, or otherwise, to the lord of whom the lands are holden, but merely enters a complaint to the ordinary or visitor to correct it. The statute 12th Car. II., which abolished military tenures, expressly excepts tenure in frank-almoigne.

Frank-Pledge, in *Law*, signifies a pledge or surety for the behaviour of freemen.

FRANKENBERG, an important manufacturing town of Saxony, circle of Zwickau, on the Zschoppau, 7 miles N.N.E. of Chemnitz. It has extensive cotton and linen factories and bleaching-works. Pop. (1849) 6988. This is also the name of a town in Hesse-Cassel, province of Upper Hesse, on the right bank of the Eder, 34 miles W.S.W. of Cassel, with 3250 inhabitants.

FRANKENHAUSEN, a town of Germany, principality of Schwartzburg-Rudolstadt, on the Little Wipper, 36 miles N.N.E. of Gotha. It consists of an old and a new town, the latter mostly rebuilt since a very destructive fire in 1833; and has an old castle, two churches, a college, hospital, printing establishment, and mineral baths. In the vicinity is a salt mine. Pop. 5000.

FRANKENSTEIN, a town in the Prussian province of Silesia, government of Breslau, and 34 miles S. by W. of the town of that name. It is connected by a branch with the Berlin and Dresden railway; and has a considerable trade. The chief manufactures are linen, woollen, and cotton goods, straw-hats, &c. Pop. (1849) 6168.

FRANKENTHAL, a town in the Rhenish circle of Bavaria, 9 miles N.W. of Mannheim, and communicating with the Rhine by a canal 6 miles in length. It owes its rise to some Flemish Protestant refugees who settled here in 1562. It rose very rapidly, so that in 1577 it became a town, and in 1682 it was the third town in the Palatinate. It suffered severely in the wars of 1688 and 1794–5. The manufactures are considerable, including linen, silk, and cotton goods, porcelain, &c. Pop. 5000.

FRANKFORT-ON-THE-MAINE (German *Frankfurt Am Main*), one of the four free cities of Germany, and so called to distinguish it from the Prussian town of Frankfort-on-the-Oder. It took its name (*Franken Furt*) from the river being fordable at this point; and is supposed to have been founded by the Franks in the fifth century. It had a palace, the seat of the early dukes of Franconia, and afterwards the frequent residence of Charlemagne. This monarch held a council here in 794. Louis the Pious built a palace at Frankfort in 822, and in 838 surrounded the town with walls and ditches. In consequence of the treaty of Verdun in 843 it became the capital of the empire of the Eastern Franks, and hither the fairs held by the Austrasians were transferred. In 1152 Frederick I. was elected here, and from that time it continued to be the place of election of the German emperors, a privilege confirmed to it by the golden bull of Charles IV. in 1356. In 1245 it was erected into a free imperial city. In the history of the latter part of the middle ages Frankfort occupies a distinguished place; many important assemblies were held within its walls; matters of peace and war were discussed; controversies were settled; and occasionally its tranquillity was disturbed by intestine quarrels. From 1562, when Maximilian II. was crowned here, it continued to be the coronation town of the emperors till the dissolution of the empire. The Thirty Years' war had but little direct influence upon Frankfort; but it was not equally fortunate in the wars of Louis XIV. In 1688-9 it escaped falling into the hands of the enemy only by its vigorous preparations for defence, while some of the neighbouring villages were plundered and set on fire. In the French revolutionary war it suffered severely, being alternately in the possession of friend and foe. In 1806 it became a member of the Confederation of the Rhine, and was made the capital of a prince primacy. In 1810 the grand duchy of Frankfort was created, with an area of nearly 2000 square miles. After the battle of Leipzig in 1813, the allies restored it to its former independence; and by the Congress of Vienna in 1815 it was made one of the four free cities of Germany, and the seat of the Germanic diet.

The city of Frankfort is situated on the right bank of the Maine, 20 miles above its confluence with the Rhine, in N. Lat. 50. 6. 43., E. Long. 8. 41. 24. It is connected with its suburb Sachsenhausen on the opposite bank of the river by a fine stone bridge of 14 arches. Its fortifications were destroyed during its occupation by the French, and their site is now occupied by public walks and gardens. It still possesses nine gates, which form the entrances to the town, two of which are in Sachsenhausen. The old town, with its narrow streets, and quaint wooden buildings, the gables of which overhang their basement stories, has a very antique appearance. The new town, however, contains many magnificent houses, not a few of which are justly entitled to the appellation of palaces. Of its squares, several are ornamented with fountains. Some of the finest houses line the quay, which extends along the right bank of the river nearly the whole length of the city. The *Römer* or council-house is not remarkable for its architectural beauty, but is historically interesting as being the place where the German emperors were elected. The *Wahlzimmer* or election-room is a spacious and handsomely furnished apartment, appropriated to the meetings of the senate. The walls of the *Kaisersaal*, or imperial hall, where the emperors were entertained on their election, and waited upon by kings and princes, are covered with portraits of the emperors —from Conrad I. to Francis II. In the archives of this building is preserved the golden bull of Charles IV. which re-

Frankfort-on-the-Maine.

Frankfort-on-the-Oder.

gulated the mode of election and number of electors. The cathedral, or church of St Bartholomew, a Gothic structure in the form of a cross, was commenced in the time of the Carlovingian princes, but the greater part of it belongs to the thirteenth and fourteenth centuries; and its tower, which is 260 feet high, is still unfinished. It contains some curious monuments, among which is one of the emperor Günther of Schwarzburg, who was slain by his rival Charles IV. In the *Wahlkapelle*, or election-chapel, the emperor was formally elected, and afterwards crowned in front of the high altar. The present German diet assembles at the residence of the Austrian ambassador, formerly the palace of the prince of Tours and Taxis, an edifice of the last century, containing 150 apartments, and richly adorned with paintings, sculptures, &c. The church of St Leonhard occupies the site of the old palace, of which no traces now exist. The *Saalhof*, a sombre-looking building of the last century, stands on the site of the palace erected by Louis the Pious. The chapel is almost the sole remains of the old building. Among the other public buildings are the *Braunfels* or old exchange, the *Börse* or new exchange, the new hall of justice, the ancient palace of the knights of the Teutonic order in Sachsenhausen, the theatre, casino, &c. The literary and scientific institutions of Frankfort are numerous, comprising a college, medical institute, natural history society, geographical society, academy of arts and sciences, philosophical society, &c. The public library contains about 80,000 volumes and 1500 MSS.; and in the museum of the Lenkenberg Society of Naturalists is the valuable collection of Dr Rüppell, the Abyssinian traveller. The Städel museum (so named from its founder, who bequeathed his collection of paintings and engravings, together with a sum amounting to about L.83,000 for building and maintaining a public gallery and school of arts) contains a good collection of paintings, chiefly of the Flemish and Dutch schools. There are also many private collections of pictures. The celebrated statue of Ariadne seated on a leopard, by Dannecker, is exhibited in the garden of Mr Bethmann, and is considered one of the finest productions of modern art. Immediately beyond the Friedburg gate is a colossal monument to the Hessians who fell there in the defence of Frankfort in 1792. Among the benevolent institutions, which are numerous, are four hospitals, an orphan asylum, deaf-mute institution, house of refuge, &c.

The chief manufactures are carpets, table-covers, oilcloth, cotton, woollen, and silk fabrics, jewellery, tobacco, playing-cards, &c. Frankfort was made a free port in 1831, and is also one of the four great emporiums for supplying Germany with merchandise. The river Maine, which is navigable to Bamberg in Bavaria, where commences the Donau-Maine Canal leading to Kelheim on the Danube, and the numerous railways which centre in Frankfort, render it the industrial and commercial centre of the S.W. and W. parts of Germany. No German city, with the exception of Berlin, is the centre of so great a number of railways. Four great lines, and several others of a more local character, meet in the city. The Main-Neckar railway leads southward to the Grand Duchy of Baden, whence railways proceed to Switzerland, Wurtemberg, and Bavaria. The Taunus railway leads west and north-west to Mayence, and to Wiesbaden. From Mayence a railway goes to Ludwigshafen, the harbour of the Bavarian Palatinate opposite Manheim, thence to Strasburg, and therefrom to Paris as well as to Switzerland. Another branch from Ludwigshafen meets the Strasburg and Paris railway at Nancy. From Wiesbaden a line is now (1855) in course of construction to Coblentz. The Main-Weser railway passes through the greater part of the two Hesses to Cassel, and communicates with Hanover, Bremen, Hamburg, &c. On the right its branches lead to Berlin and Saxony, and on the left a line will soon be opened to Cologne. The Hanau railway connects Frankfort with Hanau and the chief places on the Maine to Bamberg, from which southward with Nuremberg, Augsburg, Munich and Austria, and in another direction with Leipsic, Dresden, and Bohemia. There are also local lines to Offenbach, the chief manufacturing town of Hesse Darmstadt, to Soden, a much frequented bathing-place, and to near Romburg, one of the famous spas of Germany. Frankfort, however, is chiefly indebted for its great wealth to being the seat of extensive banking, commission, and funding transactions. In proportion to its size, it is probably the richest city in the world. There are about twenty first-class banking houses; among these are the Rothschilds, Grunelius, Metzter, and others, well known in the commercial world. The number of those in the stock and exchange business amounts to at least 200. A city bank with a capital of 10,000,000 florins was established last summer, and has just (1855) commenced business operations. The two fairs of Easter and Michaelmas are still much frequented. Goethe was born here in 1749. Civil pop. (1852) 62,361, being 47,100 Protestants, 10,661 Catholics, and 4600 Jews; military, 5650—1717 being Austrians, 1713 Prussians, 1391 Bavarians, and 829 natives. The population of Frankfort is but slowly increasing, on account of the old illiberal laws still in force as to admission to citizenship. Only such are admitted as can prove their ability to maintain a family; so no merchant can be admitted unless he prove that he possesses at least 5000 florins, and generally persons possessing that sum, or even more, are not admitted unless they marry a citizen's daughter, in which case the law is more favourable. The ancient law is also still in force, that none shall mend a shoe or drive a nail unless he be a master and a member of one of the corporations, and he cannot become a member unless he be the son of a citizen, or marry a citizen's daughter. The restrictions to which the Jews were long subject have now mostly been removed. They are entitled to vote at the elections of members to the legislative assembly, and may return four of their own number; they are also admissible to all offices not connected with the senate, the permanent assembly of the citizens, law, religion, or education. The inhabitants of Sachsenhausen are mostly of Saxon descent, and distinguished from their fellow-citizens in manners, dress, and language, as well as occupations, being mostly employed in gardening, fishing, &c.

The city, with a small territory of 38 square miles lying immediately around it, constitutes the free state of Frankfort. The government is vested in a senate, a legislative assembly, and a permanent committee of citizens. The senate, which exercises the executive power, is composed of 44 members, divided into three benches—justices, senators, and councillors, and having two presidents, one chosen from each of the two first-mentioned benches. The legislative assembly is composed of 94 members, of whom 20 are senators, 20 members of the permanent committee of citizens, 45 chosen annually by the citizens collectively, and 9 deputies from the rural districts. The permanent committee consists of 60 members chosen from among citizens of all ranks. The legislative assembly meets annually in the month of November, and sits for six weeks; and its sanction is requisite to all new laws, the budget, &c. With the free cities of Lübeck, Bremen, and Hamburg, Frankfort occupies the seventeenth place in the Germanic Confederation. It enjoys one vote in the general assembly (*Plenum*), and furnishes a contingent of 683 men to the federal army. Pop. of the state (1852) 77,971.

Frankfort-on-the-Oder, a town of Prussia, province of Brandenburg, and capital of the government of Frankfort, stands on the left bank of the Oder, 50 miles E. by S. of Berlin, with which, since 1842, it has been connected by railway. The town is regularly built, and surrounded by old walls with towers and ditches. It has three suburbs, one of which stands on the opposite bank of the river, and communicates with it by means of a wooden bridge. The university founded here in 1506 was removed to Breslau in 1810. Frankfort has a Roman Catholic and six Protestant churches, a synagogue, gymnasium, obstetric school, orphan asylum, workhouse, theatre, &c. Being the capital of a government, it is the seat of a superior and other judicial tribunals, of boards of taxation, agriculture, &c. Though inferior to its namesake on the Maine, it is a place of considerable commercial activity, being situated on the high road from Berlin to Silesia, and on a navigable river communicating by canals with the Vistula and the Elbe. It has three annual fairs in the months of February, July, and November, attended by merchants not only from Germany, but also from other parts of Europe. It has manufactures of woollen and silk goods, stockings, gloves, leather, tobacco, sugar, brandy, mustard, &c. Immediately beyond the bridge is a monument to Prince Leopold of Brunswick, who was drowned here in 1785 while attempting to rescue an unfortunate family from an inundation of the Oder. At Kunnersdorf in the vicinity, Frederick the Great was defeated with great loss by the Austrians and Russians on 12th August 1759. Pop. (1849) 29,969.

FRANKFORT, the capital of the state of Kentucky, North America, occupies a very picturesque situation on the east side of the Kentucky river, 62 miles above its confluence with the Ohio. On the opposite bank of the river, which is here 80 yards wide, stands the suburb of South Frankfort, connected with the town by a chain bridge. Frankfort is well and regularly built, and many of the edifices are of white marble. It possesses some trade; steam-vessels of considerable burden come up to the town, and a railway connects it with Louisville on the Ohio. Among its public buildings are the state-house, penitentiary, court-house, jail, and market-house. It was founded in 1786, and was made the seat of government in 1792. Pop. (1850) 4372.

FRANKLAND'S ISLANDS, a cluster of small islands on the north-east coast of New Holland, about six miles from the land. E. Long. 146., S. Lat. 17. 12.

FRANKINCENSE. See INCENSE.

FRANKLIN, BENJAMIN, one of the most distinguished of Americans, alike in science and in politics, was born at Boston in New England, Jan. 17 (N.S.) 1706. His paternal ancestors had lived for many generations on a small freehold in the village of Ecton in Northamptonshire. About the year 1682 his father, Josiah Franklin, in company with some of his neighbours, emigrated to New England, for the sake of that religious liberty which, as nonconformists, was denied them at home. Of seventeen children Benjamin was the youngest but two. He early displayed a strong taste for reading. At the age of eight he was sent to the grammar-school, his father intending to devote him, "as the tythe of his sons," to the church. The cares of a numerous family soon interfered with this design, and at the end of a year Benjamin was sent to another master to learn writing and arithmetic. When ten years old he was taken to assist his father in his business as a tallow-chandler and soap-boiler, a pursuit to which the aspiring boy soon manifested a strong repugnance. He was extremely desirous to go to sea, but the influence of his father, a man of strong judgment, who took great pains in the moral training of his family, prevailed to keep him at home. The boy's love of books found little scope in the small library of his father: it consisted chiefly of works of polemical theology, which were read through with little advantage, but contained, among other things, a copy of *Plutarch's Lives*, Defoe's *Essay on Projects*, and Mather's *Essay to do Good*. The latter, Franklin thought, exercised considerable influence on his mind. Already in the practical and tangible, the inquiring but unimaginative mind of the boy, "father of the man," had found its congenial aliment.[1] His father at length determined to make Benjamin a printer; and in his twelfth year he was bound apprentice to his brother James. He soon became an excellent workman, and now found more access than ever to books, to which he devoted all his leisure hours. As is usual, even with the least poetical of youths, he essayed rhyme. One or two of his ballads sold well in the streets; but the sound advice of his father discouraged him from further attempts, and impressed him with the necessity of attention to prose composition. An odd volume of the *Spectator* furnished the stimulus to his first efforts, and the model of his style. By carefully cultivating the practice of composition, he at a comparatively early age acquired considerable ease and dexterity in writing. His mature style was extremely clear and simple, generally nervous, often lively, and in rare instances touched with eloquence. The same practical sagacity which so early distinguished his intellectual efforts was manifested in his control over his passions. At the age of sixteen he met a book recommending a vegetable diet. He at once adopted it, saving time and money by the lightness of his meals, and devoting the gain in both to his one luxury of books.[2] About this time he read the *Memorabilia* of Xenophon. The Socratic method of reasoning greatly charmed him; and having already imbibed sceptical principles from Shaftesbury and Collins, he found it peculiarly suited to puzzle others without committing himself to positive assertions. Gradually, however, he left off this method, retaining only the habit of expressing himself with caution and diffidence, a habit of which his acute knowledge of human nature afterwards led him to see the great utility.

In 1721 his brother established a newspaper in Boston,[3] and Benjamin was employed at once as a compositor, printer, and deliverer. Though thus abundantly occupied, he determined to try his hand also as a contributor, and accordingly sent in several anonymous essays. They were highly approved of; but when the authorship was discovered, his brother, apprehensive of Benjamin's becoming too vain, manifested some displeasure. From this time apparently mutual jealousies sprang up between them. Benjamin submitted impatiently to the domination of his brother. "Perhaps," he says, "this harsh and tyrannical treatment of me might be a means of impressing me with the aversion to arbitrary power which has stuck to me through my whole life." An opportunity soon occurred for a disruption. An article in the paper gave offence to the provincial government; James was censured, and imprisoned for a month, and ordered no longer to print his newspaper. To evade this order, it was determined to print the paper in Benjamin's name; and in order to overcome the legal difficulty, the apprentice's indenture was formally discharged, while a new one was privately signed, binding him to fulfil his engagement. On the breaking out of new differences with his brother, Benjamin unfairly took advantage of this compromise, and asserted his freedom. This he styles one of the first *errata* of his life. His brother having warned all the printers of Boston against him, Benjamin determined to leave the city, and accordingly made his escape to New York, where he found himself, in his seventeenth year, with little money and no friends. Obtaining no employment, he set out for Philadelphia. His own account of this journey, and of his first appearance in the streets of Philadelphia, eating a halfpenny roll, with another under each arm, is one of the most interesting passages in his autobiography. Here he formed an engagement with a printer named Keimer, who had recently commenced business. Franklin's industry and frugality soon secured him a comfortable position. His abilities attracted the notice of Sir William Keith, the governor of the province, who encouraged him to set up as a printer on his own account, and even proposed that he should go to England to procure the necessary printing-stock. Franklin set sail, accompanied by his friend James Ralph,[4] arrived in London on the 24th December 1724, and only then discovered that his patron's promises were entirely delusive.[1] He immediately found employment, however. At Palmer's, in Bartholomew's Close, he was engaged in printing the second edition of Wollaston's *Religion of Nature.* Some of the arguments appearing to him defective, he wrote and printed his remarks upon them under the title, *A Dissertation on Liberty and Necessity, Pleasure and Pain.* His aim was to prove that "whatever is is right," and that virtue and vice are mere names. This pamphlet was the means of introducing him to several men of some note, among others to Dr Mandeville. Five years later he had come to very different conclusions on these subjects, and wrote a tract demonstrating the fallacy of his former opinions. Shortly after this he removed to a more extensive printing-house, where his temperance, intelligence, and industry, soon gained him respect and influence.

---

[1] There is an anecdote which seems characteristic of what the boy Franklin may be conceived, as the proper type of sharp irreverent young America. His father observed the old Puritan fashion of saying very long graces before and after meat, which caused much weariness to Benjamin. Once, when they were salting the winter store of provisions, he said, "Father, could you not say grace over the cask, once for all; it would be a vast saving of time."

[2] He did not practise Vegetarianism long, his good sense yielding to the force of the argument suggested by seeing a small fish taken out of the inside of a bigger one.

[3] *The New England Courant.* Franklin calls this the *second* newspaper published in America. Mr Sparks (*Works of Franklin*, vol. i., p. 23) shows that it was the *fourth*. "About this time, 1771," says Franklin, "there are no less than five and twenty." In 1850 there were *two thousand eight hundred.*

[4] Afterwards a man of some note as a party writer on history and politics, and commemorated by Pope in the *Dunciad*.

On the 23d July 1726 he left London in company with a Mr Denham, who was about to open a store in Philadelphia. With him he lived several months, assisting in the management of the business. About this time he established a club for mutual improvement and discussion, called the *Junto,* which existed for many years, and proved of no small public utility. On the death of Mr Denham, Franklin resumed his proper work, and again found employment with his former master, Keimer. He soon put the business on a good footing, and, besides his duties as printer and warehouseman, made ink, and even types, for the establishment. As the other hands improved under Franklin's management, Keimer thought he could do without him, and, after a quarrel, they separated. Soon after, however, Franklin was prevailed upon to assist Keimer in executing an order to print bank notes in New Jersey. His mechanical ingenuity here became available in the construction of a copperplate press—the first of its kind seen in America—and the cutting of ornaments for the bills. On leaving Keimer, he had resolved, with one of his fellow-workmen, Meredith, to set up an establishment of their own. Immediately on his return to Philadelphia this design was put into execution; and from that time the prudence, industry, and perseverance of Franklin were rewarded with steadily advancing prosperity. At this time there was but one newspaper in Pennsylvania. Franklin determined to start another. The design came to Keimer's ears, and he hastened to forestall it. After a few months of unsuccessful management he was glad to hand it over to Franklin, in whose skilful hands it became both influential and profitable. In 1729 the want of paper-money was much felt in the colony, and the subject was discussed in the Assembly. Franklin published a pamphlet urging the necessity of a fresh issue; and on the passing of a bill to that effect, he was rewarded by being employed to print the money. His business was now flourishing. On the 1st of September 1730 he married Miss Deborah Reid, to whom he had been engaged on leaving America for England. He neglected her during his absence, and she married another, who soon after separated from her. Franklin found in her a faithful and prudent helpmate during a period of forty-four years. At this time he tells us there was not a good bookseller's shop south of Boston. Lovers of literature were obliged to send to England for supplies. In 1731 Franklin set on foot a subscription for a library. The scheme began with fifty subscribers, mostly young tradesmen. It prospered, like all Franklin's undertakings; and in 1742 a charter was obtained for the "Philadelphia Library Company,"—"the mother of all the North American libraries, now so numerous." His command of books was now greatly increased, and in the midst of unrelaxing application to business he daily devoted an hour or two to study. About this time he conceived the project (characteristic at once of the man and the age) of arriving at moral perfection, "to live without committing any fault at any time." His plan for attaining this happy result is described in his autobiography. While acknowledging that he never arrived at the perfection aimed at, he expresses his conviction that he was a better and a happier man from having made the attempt. He always intended to enlarge this scheme into a treatise, to be called *The Art of Virtue,* but never carried out his design. It was connected with an extensive project for the establishment of a universal society for the promotion of virtue. Even in his old age he does not seem to have regarded this scheme as chimerical.

In 1732 he first published the almanac which, under the name of *Richard Saunders,* or *Poor Richard's Almanac,* became so celebrated. Its great aim was, through choice aphorisms and proverbs, to inculcate industry and frugality, "as the means of procuring wealth, and thereby securing virtue." In the almanac for 1757 these sayings were collected into a discourse, which has been often reprinted and translated into many languages, under the title of "The Way to Wealth." Its influence in Pennsylvania was thought, Franklin says, to have been considerable, and there can be little doubt that the general character of his countrymen still bears testimony to their veneration for the precepts of Poor Richard. It is to be wished that his further advices on the exclusion of "all libelling and personal abuse" from newspapers were followed with equal fidelity. In 1733 he began to study languages. He soon mastered French, so far as to read it with ease. He next studied Italian and Spanish. These he found so helpful to the acquirement of Latin, that he concluded the modern practice of studying the dead language first to be grounded on a mistake.

Franklin's merits as a citizen now began to receive public recognition. In 1736 he was appointed clerk of the Assembly,[2] and in the following year deputy-postmaster-general of America. "I now began," he says, "to turn my thoughts to public affairs, beginning, however, with small matters." The reform of the city watch and the establishment of a fire company were his first services. In 1743 he drew up a plan for the establishment of an academy in Philadelphia. Finding obstacles in the way, he did not publish his views for some time. Six years after he was completely successful. The academy then established was the foundation of the University of Philadelphia. In 1744 he succeeded in establishing a scientific society, which, after various changes, became the *American Philosophical Society,* now the *American Academy of Sciences.* When war broke out in this year between Britain and France, the defence of the colony became a matter of serious anxiety. The governor had in vain striven to induce the Assembly (chiefly Quakers) to pass a militia bill. The practical energy of Franklin overcame the difficulty. As was his usual practice, he promulgated his views in a pamphlet, entitled *Plain Truth,* which produced an immediate effect. At a public meeting held soon after 1200 persons subscribed their names as members of a voluntary defence association. The number afterwards increased to 10,000. These were speedily formed into regiments, and provided themselves with arms. To defray the expense of erecting a battery below the town, Franklin proposed a lottery; and the scheme was immediately carried into execution.[1] Franklin now began to be looked upon as a man of public importance, and in all matters connected with the militia his advice was sought by the governor and his council.

---

[1] "He wished," says Franklin, "to please everybody; and having little to give, he gave expectations." He commends him notwithstanding as a sensible man and a good governor.

[2] One of the members opposed his election in the following year. Franklin's method of gaining his goodwill indicates his acute knowledge of men. He requested the loan of a scarce and curious book from the gentleman's library, and returned it soon after with a courteous note of thanks. The lender was thenceforth his friend. "He that has once done you a kindness," adds Franklin, "will be more ready to do you another than he whom you yourself have obliged."

The comparative leisure afforded by the increasing prosperity of his business Franklin now devoted to scientific pursuits, for which his extraordinary ingenuity, acuteness of observation, and sound judgment, peculiarly qualified him. Whilst visiting Boston in 1746, he heard a lecture on electricity, by a Dr Spence from Scotland. He became deeply interested in the subject, and thenceforth devoted much time to electrical experiments. Shortly afterwards Mr Collinson, F.R.S., presented a glass-tube to the Philadelphia Library Company, with directions for its use. To him, in March 1747, Franklin communicated the first results of those observations and experiments which contributed so much to his fame, and ranked his name among those of great discoverers. His views on the nature of electricity, as is not unusual in such cases, were treated at first by many of the learned with comparative contempt, afterwards opposed, and finally universally accepted and confirmed. The Royal Society, in which his first observations on the identity of lightning and electricity were laughed at, in 1753 conferred on him their highest distinction, the Copley medal, and afterwards elected him into their number without solicitation and free of expense. For a particular account of his electrical experiments, see ELECTRICITY.

Anxious as he was to enjoy leisure for the pursuit of his favourite studies, he now began to be in request for public business. He was made a justice of peace, town-councillor, alderman, and representative. The latter office, he says, he was glad to accept, as, besides his ambition to be of use to the public, he had begun to tire of the discussions in which, though compelled as clerk to be listener, he could take no part, and used to amuse himself in drawing magic squares or circles,[2] or anything to avoid weariness. Next year he was appointed with the speaker to negotiate a treaty with the Indians. In 1751 Dr Bond communicated to him his plan for the erection of a hospital in Philadelphia. Franklin took it up warmly, and it was speedily realized. In 1753 he was appointed joint postmaster-general. Under his management the American post-office flourished as it had never done before. In 1754 he attended as one of the Pennsylvanian commissioners at the congress held at Albany, to confer on the means of defence in the event of a rupture with France. Several of the commissioners came provided with plans for a union of all the colonies under one government, among the rest Franklin. His plan received the preference. It was rejected, however, by all the assemblies; and the Board of Trade, to whom it was submitted, did not think it worth recommending to the crown. The former thought there was too much *prerogative* in it, while in England it was thought too *democratic*.[3] From this double objection Franklin argued that his plan had hit the true medium, which, if followed, would have prevented the subsequent revolution. In the following spring he rendered eminent service to General Braddock, in procuring waggons and provisions for his troops. With the ready public spirit which so marked his character, he advanced more than L.1000 of his own money for that purpose. The thanks of the assembly were voted to him on his return from this expedition.

In the disputes which for some years back had been growing ever more serious between the Pennsylvanian Assembly and the proprietaries,[4] Franklin, as might be expected, was one of the strongest opponents of what he considered the unjust and selfish claims of the latter, and gradually came to be looked upon as the leader of the opposition. He spoke seldom, and briefly, but always to the point, and with effect. An appropriate anecdote or apologue was one of his favourite and most effective means of persuasion. About this time he introduced and carried a bill for the establishment of a voluntary militia. While the organization was going on, he undertook, on the solicitation of the governor, to place the north-western frontier in a state of defence. He soon raised a body of 560 men; and in about six weeks accomplished his somewhat difficult and dangerous commission with perfect success, erecting three wooden forts, which at the end of that time he handed over manned and armed to the charge of a military officer. On his return he was chosen colonel of the Philadelphia regiment, and received such marks of honour as gave considerable offence to the proprietors. The assembly having at length resolved to petition the king against the proprietary government, Franklin was deputed as their agent to Britain, and on the 27th July 1757 arrived in London.

Here he found strong obstacles and prejudices to contend against, the assembly and people of Pennsylvania being generally represented by the press as the selfish and refractory opponents of their rightful governors. He found that little was to be expected in the way of concession from the proprietors, while the eyes of the ministry and people of England were too intently directed to Germany (where the Seven Years' War was just going on), to heed much the rising of the little cloud that foreshadowed so great a tempest in the west. Franklin took every opportunity to dispossess the public mind of the unfavourable opinions propagated against his countrymen. Early in 1759 appeared a work entitled *An Historical Review of the Constitution and Government of Pennsylvania*. Though betraying a strong party bias it gave a clear view of the subject, and being written with point and vigour, produced a considerable effect. It had been composed under the direction and with the assistance of Franklin.[5] His business, meantime, made little progress. He wished much to see Pitt, but that great statesman was then too much occupied to be accessible. Franklin's experience and sagacity were duly valued by the government. Whether or not it be true that Wolfe's successful expedition to Canada was suggested by him, it is certain that he was deeply impressed with the importance of these colonies to Britain, and was zealous in inculcating his views.[6] In 1760, when the question of retaining them was under discussion, he wrote an able pamphlet on the subject, which probably contributed to influence the ministerial decision. In the summer of that year he visited Scotland, where he experienced a most cordial and distinguished reception, and formed a lasting friendship with some of the most eminent men then to be found in Edinburgh, such as Hume, Kames, and Robertson.[7]

---

[1] Franklin was sent to borrow cannon for this battery from Governor Clinton at New York. At first the request was peremptorily refused. They met at dinner, "where there was great drinking of Madeira wine." The governor softened so far as to grant *six* guns. As the wine passed, his liberality expanded to *ten*; and before the evening closed he good-naturedly offered *eighteen*.

[2] Some very curious specimens of these are given in his works. Sparks' edition, vol. vi., p. 100–105.

[3] The principal feature of this plan (the germ of the Union) was the appointment of a president by the crown, with a grand council nominated by the colonial assemblies.

[4] By this name were designated Penn's immediate successors Richard and Thomas. See PENNSYLVANIA.

[5] This work has generally been attributed to him. In a letter to David Hume, printed for the first time in Sparks' edition of his works, he disowns the authorship, with certain exceptions. The real author was probably Ralph.

[6] A very remarkable passage on the subject occurs in one of his letters to Lord Kames. After the revolution he was equally anxious to secure Canada to the States.

[7] In the same letter to Lord Kames he says of this visit, "On the whole I must say I think the time we spent there was six weeks of the *densest* happiness I have met with in any part of my life." He visited Scotland again in 1771.

After a delay of nearly three years, he succeeded in bringing his business to a comparatively successful termination; an act of the Pennsylvanian Assembly for raising a tax of L.100,000, from which the proprietary estates were not exempted, having, under certain limitations, received the royal assent in June 1760. The *principle* for which the Pennsylvanians had contended was so far conceded.[1] Some financial business still detained him. In the summer of 1761 he visited Holland and Flanders. Meanwhile his scientific pursuits were not neglected. Among other results of his ingenuity was the construction of a musical instrument[2] (the *Armonica*), which was for some time very fashionable. Before leaving England he received the degree of a doctor of laws from Edinburgh and Oxford. St Andrews had conferred the same honour on him some time before. The government about the same time testified their sense of his merits by appointing his son governor of New Jersey.[3]

On his return to Philadelphia (November 1762), he received the thanks of the Assembly, and a grant of L.3000 for his services. The next public transaction in which his ability and influence were exhibited, in strong contrast to the weakness of the provincial government, was the alarming insurrection subsequent to what were called "The Paxton Murders." By his prompt and judicious interference a large body of citizens was armed, and the insurgents were persuaded to retire peaceably. Meantime the contest with the proprietaries had waxed more bitter than ever. The Assembly, exasperated beyond endurance, at length passed a series of resolutions in favour of transferring the government entirely to the crown. Franklin strongly advocated this scheme. A large majority resolved to petition the king. The petition drawn up by Franklin was signed by him as speaker, to which office he had just been chosen. At the next election of representatives, Franklin lost his seat by a trifling minority, after having held it for fourteen years without asking a vote. His party, however, triumphed in the Assembly, and to the disgust of his opponents, Franklin was appointed their special agent to defend the petition at the court of Britain. He arrived in London on the 10th of December.

Though charged with a special commission, he had instructions to use his efforts against the passing of the Stamp Act, "the mother of mischief," as in one of his letters he designated it. These efforts, though zealous and unremitting, were in vain. The question of repealing the act came before parliament early in 1766; and Franklin was summoned to give evidence on the subject at the bar of the House of Commons. His perfect knowledge of the subject in question, the clearness and readiness of his replies, and the manly dignity of his bearing, produced a profound impression on the house, and contributed much both to heighten the public estimate of himself, and to hasten the decision of parliament. In the summer of this year he visited Germany in company with his friend Sir John Pringle. At this time he seems to have studied the whole subject of the mutual relations of Britain and the colonies with much attention, and to have arrived at those conclusions which guided his future conduct in the struggle. The question was mooted about this time, whether a representation of the colonies in the Imperial Parliament might not tend to promote union. This, in Franklin's opinion, afforded the only sure basis of a permanent reconciliation.[4] In the following autumn he visited Paris, where he was received with flattering distinction. He was introduced to the king and royal family, and made the acquaintance of the most distinguished Frenchmen of the time. He was now desirous to return to America, seeing no hope of drawing the attention of government to the object of his mission. He was detained, however, by a letter informing him of his having been appointed agent for Georgia. In the following year he received a similar charge from the state of New Jersey; and in 1770 from that of Massachusetts. His well-known views on the subject of America, and the freedom with which he was in the habit of expressing them, made him obnoxious to many of the ministers, and particularly to the colonial secretary, Lord Hillsborough.[5] Rumours had at various times come to his ears of an intention to deprive him of his office of postmaster-general. Whether true or false, they affected him little. He was equally indifferent to the counter-reports of an intention to raise him to some more important office.[6] The occasion of his actual dismissal from office was a transaction which, though dictated on his part by what he considered a sense of duty, subjected him at the time to the severest obloquy. In December 1772, there were put into his hands[7] certain letters from the governor and lieutenant-governor of Massachusetts, to Mr Thomas Whately, a member of parliament connected with the government, representing the people of that province as purely factious in their opposition to the government imposts, and recommending those coercive measures which produced such mischievous results. Franklin having hitherto attributed these obnoxious measures to the home government, and expressed himself accordingly in his letters to America, thought it his duty to communicate these documents to the Assembly, whose interests they so much concerned. The Assembly petitioned the Board of Trade to remove the authors of the letters from office. Counsel was engaged on both sides, and the case came before the privy-council at a very full meeting on the 29th January 1774. The solicitor-general, Wedderburn, afterwards Lord Loughborough, conducted the defence, and made it the occasion of a bitterly sarcastic and abusive attack on the character of Franklin, who stood by apparently unmoved, while their lordships testified their satisfaction by laughter and cheers. The petition was rejected as "groundless, vexatious, and scandalous," and next day Franklin was informed that his services as postmaster-general were no longer required. Though it is certain that he deeply resented the insult offered to him on this occasion,[1] there is no good ground for assuming that it altered in any degree his views of the question between Britain and America. He had long been convinced of the hopelessness of a reconciliation. After this he had no further intercourse with the ministry; and he now resolved to return home as soon as possible. He was advised, however, to await the issue of the Congress about to be held in America. The petition of Congress to the king arrived in December. All the colonial agents, except Franklin and two others, declined to present it. Their request to be heard in support of it at the bar of the House of Commons was refused, and the petition was rejected by an overwhelming majority. After this Franklin still occupied himself, at the solicitation of his friends Dr Fothergill and Mr Barclay, in drawing up a plan of reconciliation. It was shown to Lord Howe, and several other ministers, but the terms were considered inadmissible, and the affair dropped. Towards the end of the year he had frequent interviews with Lord Chatham, who was then preparing a bill for the settlement of the American difficulty. In reply to an insinuation of Lord Sandwich, in the debate of January 20, 1775, that great man pronounced a high eulogium on Franklin, and ended by declaring that he was "an honour not to the English nation only but to human nature!"

---

[1] Franklin's share in this controversy subjected him to special hostility. The following testimony from Thomas Penn, in a letter to Governor Hamilton, is valuable. "I do not find that he has done me any prejudice with any party, having had conversations with all, in which I have studied to talk of these affairs; and I believe he has spent most of his time in philosophical and especially in electrical matters, having generally company in a morning to see those experiments."

[2] Constructed on the principle of educing graduated tones from glasses filled in various measure with water.

[3] This son, William Franklin, remained a firm royalist all his life. His opposition to his father produced a temporary estrangement: they were afterwards reunited, but the old man remembered it in his will.

[4] The wisdom and moderation of his views is seen in the following passage from one of his letters about this time to Lord Kames. "America, an immense territory, favoured by nature with all advantages of climate, soils, great navigable rivers and lakes, must become a great country, populous and mighty, and will, in a less time than is generally conceived, be able to shake off any shackles that may be imposed upon her, and perhaps place them on the oppressors. In the meantime, every act of oppression will sour their tempers, lessen greatly if not annihilate the profits of your commerce with them, and hasten their final revolt; for the seeds of liberty are universally found there, and nothing can eradicate them. And yet there remains among that people so much respect, veneration, and affection for Britain, that if cultivated prudently, with a kind usage and tenderness for their privileges, they might easily be governed for ages, without force or any considerable expense. But I do not see here a sufficient quantity of the wisdom that is necessary to produce such a conduct, and I lament the want of it."

[5] His lordship appears to have been particularly offended by Franklin's success with the Board of Trade in reference to *Walpole's Grant*. As far back as 1766 a company was formed for the settlement of a new territory on the Ohio. Mr Thomas Walpole, a London banker, was at its head, and Franklin was a leading member. Lord Hillsborough opposed their petition for a grant with great zeal, but without success.

[6] In 1768 a vague overture was actually made to Franklin by the Duke of Grafton, through Mr Cooper, secretary of the treasury, but with no result.

[7] How the letters were obtained has never been discovered.

Having at length wound up his business in England, Franklin sailed for America, and arrived at Philadelphia on the 5th of May. He was chosen a member of Congress next day, and thenceforward he was extensively occupied in all its most important business. On the establishment of a new post-office, he was appointed postmaster-general. In March 1776 he was sent as one of the commissioners to negotiate for the co-operation of Canada, an unsuccessful journey, the fatigues of which proved seriously injurious to his health. When the question of independence came to be discussed, he was among the most emphatic in the affirmative, and was selected as one of the five to prepare the declaration.[2] Soon after he was appointed President of the Convention appointed to frame a new constitution for Pennsylvania. The most remarkable feature in this constitution (afterwards changed), viz., a single legislative assembly, is supposed to have originated with him—this having always been one of his favourite political theories. In the futile attempt at negotiation with Lord Howe in the spring of 1776 he bore a leading part. Towards the end of the year the Congress resolved to seek assistance from the European powers, and especially France. Franklin was specially qualified for such an embassy, and though adverse to the policy of seeking foreign alliances, which he opposed in Congress, he was unanimously nominated commissioner-plenipotentiary, in conjunction with two others, to the court of France. Before sailing he put three or four thousand pounds, all the money at his command, at the disposal of Congress as a loan.

He arrived in Paris on the 21st December, and shortly after removed to the suburban village of Passy. Here he resided while in France, an object of interest and reverence to the lively citizens of Paris; adapting himself with easy tact to the national tastes and habits, while his personal peculiarities derived piquancy by contrast. To the brilliant intellectual circle with whom he associated it was specially charming to find in the scientific sage, whose primitive aspect and homely wisdom seemed fresh from antique times, not only an exponent, but a living illustration, of those wonder-working "ideas" by which the new Millennium of "Humanity" was to be achieved. His negotiation was eminently successful. The result of the campaign of 1777, to use the words of Franklin's grandson and biographer, *fixed the French nation in their attachment to the infant republic.*" On the 6th February 1778 the treaties were signed, and on the 20th of March the American plenipotentiaries were received in due form at Versailles. The other commissioners were recalled in the following year, and Franklin was appointed sole minister-plenipotentiary of the United States at the Court of France. The heavy and important duties connected with that office he discharged for the next six years. Attempts were made more than once to have him recalled, but the value of his services was too notorious to give much weight to the charge brought against him of neglecting the interests of his country and being too subservient in his relations to the French cabinet. In addition, moreover, to his proper official work, he carried on an extensive correspondence, and was incessantly harassed by visits, proposals, and applications of the most miscellaneous character.[3] Science, too, continued still to occupy some of his time. He frequently attended the meetings of the Academy, of which (as of the principal learned societies in Europe) he was a member; and in 1779 read a paper on the Aurora Borealis. In 1784 he was appointed to the head of the commission for inquiring into the nature of the experiments then extensively practised by Mesmer and his disciples, and by them attributed to *animal magnetism.* For that delusive term Franklin substituted the word *imagination.* His concern for the interests of science was nobly displayed in his sending, on his own authority, a circular to all the commanders of American cruisers requesting them to offer no molestation to the ship of Captain Cook.[4] As ambassador he was much occupied in negotiating treaties with the principal European powers, a service in which his extreme foresight, tact, and firmness enabled him to secure signal advantages to his country. The provisional treaty with Britain was signed November 30, 1782, and a treaty with Sweden in the following spring. In 1781 Franklin had requested to be relieved from his office; the Congress declined to accept his resignation, but complied, on a repetition of his request in 1785. His last official act was the signing of a treaty with Prussia, containing a new article framed by himself against privateering in time of war.[5]

On the 14th September 1785 he arrived in Philadelphia. On the voyage he had occupied himself in writing on "Improvements in Navigation," on "Smoky Chimneys," and in renewed experiments to ascertain by the temperature the course of the Gulf Stream. He was received with every demonstration of joy, and congratulations from all the public bodies. Next day he was appointed a member of the supreme executive council of Philadelphia, and soon after president of the state. Surrounded by his offspring, at the head of a community which looked up to him with the deepest veneration, enjoying comparative leisure for the cultivation of the pursuits which still formed his chief delight, the few remaining years of his life passed happily away, despite the gradual inroads of disease. In May 1787 he was chosen a member of the convention appointed to frame the constitution of the United States.[1] His motion for prayers in the convention is the most remarkable record of his share in its proceedings, and affords an impressive proof of that religious feeling in which he has often, but unjustly, been regarded as wholly deficient. The conduct of the Congress, in neglecting to settle his accounts, and bestow some adequate compensation for his long and faithful services, seems to have wounded his spirit not a little. To the last he was occupied in works of usefulness and philanthropy. The improvement of the condition of the negroes, and the alleviation of the miseries of public prisons, engaged much of his attention. His last public act was to sign a memorial to Congress as President of the Abolition Society of Pennsylvania. The last paper he wrote, twenty-four days before his death, was an ingenious and spirited parody on a speech delivered in Congress in defence of slavery. For many years he had suffered severely from gout and stone. About the beginning of April 1790 he was attacked by fever, and on the 17th he expired, in the eighty-fifth year of his age. He was buried with great solemnity amidst an immense concourse of people. Congress went into mourning for a month. The National Assembly of France, on the motion of Mirabeau, put on mourning for three days; and numerous other testimonies of respect were offered to his memory in the French metropolis. No monument has yet been raised to him by the citizens of Philadelphia.

---

[1] His biographers mention as a significant circumstance that he did not put on again the suit of clothes he wore on that occasion till the day that he signed the treaty with France as American plenipotentiary.

[2] The following anecdote is related in connection with the signing of this important document. "We must be unanimous," Hancock said, "there must be no pulling different ways, we must all hang together." "Yes," replied Franklin, "we must indeed all hang together, or most assuredly we shall all hang separately."

[3] The journal of one day (Dec. 13, 1778) records the following visits. 1. The inventor of a wonderful self-propelling machine. 2. A proposal to levy men for a piratical expedition to Britain. 3. A plan for concealing arms, &c., on the person without suspicion. 4. "Received a parcel from an unknown philosopher, who submits to my consideration a memorial on the subject of *Elementary Fire,* containing experiments in a dark chamber." The "unknown philosopher" was Jean Paul Marat.

[4] In acknowledgment of this act of humanity a gold medal and a copy of Cook's Narrative were presented to him by the Board of Admiralty, with the king's approbation.

[5] Notwithstanding Franklin's opposition to privateering, he considered his own services in this respect worthy of enumeration, in 1788, among his claims on the United States.

America has produced men of genius and ability whose names rank high in science, literature, and politics, but no man in all respects so remarkable as Benjamin Franklin, the first of her citizens who won a European fame. Embodying as he did in a high degree those qualities which have raised the American nation to so commanding a position among modern states, his influence over the character of that race has been greater than that of any other man born in America. His most obvious characteristic was common sense, sagacity, practical wisdom in the management of affairs, whether small or great. In all things he was a man of business; and as he attempted no enterprise which his quick discernment, calculating prudence, and sound judgment did not approve as feasible, his industry, tact, and indomitable firmness crowned all his undertakings with complete success. In his private life he was the personification of frugality; but while he ever kept a steady eye to his personal interests, no man excelled him in public spirit, and his devotion to the service of his country was genuine and unswerving. Passions and affections were less strong with him than intelligence and prudence, but neither was his heart cold nor were his sympathies narrow; and though eminently worldly wise, he was not less conspicuously distinguished by zeal for the good of his fellow men. On the side of imagination, and in all that connects man with the infinite, the mysterious, and the beautiful, he was signally deficient. Utility was to him the test of all human things and pursuits; in the world of practical life he lived and moved and had his being; and in that world reason wielded the empire over faith, and reverence shrank into littleness before the ambition of independence. Yet it would be extreme injustice to Franklin to say that his thoughts and feelings were bounded by the narrow limits of a sordid utilitarianism. His devotion to science alone would suffice to prove the opposite; for though all his researches were guided by a practical aim, if he had not loved truth for her own sake he could never have won from her such secrets as he did.[2] As a statesman and diplomatist, he carried into the high sphere of national policy, and with similar results, those qualities which had stamped success on all his private undertakings. No Briton, indeed, can look back with admiration to that inveterate hostility of his which scrupled not at devices for subjecting to the foot of foreign invaders the country that nursed his fathers and taught them how freedom may be kept or won. Yet it is but just to remember that that enmity was provoked by contemptuous rejection of long advice, and the oppression that makes wise men mad, and that its object was not the people of Britain, but the rulers for whose obstinate folly they were made to suffer. At this date, at least, it is only extreme prejudice that will deny the merit of rare felicity to the epigram of Turgot—*Eripuit cœlo fulmen sceptrumque tyrannis.*

The most complete edition of Franklin's works is that of Jared Sparks, in 10 vols. 8vo, Boston 1840, containing numerous letters and papers not included in that published by his grandson, William Temple Franklin, in 1817, London, 6 vols. 8vo. (A. N.)

FRANKLIN, Sir John, Rear-Admiral of the Blue, was a native of Spilsby, in Lincolnshire. Sprung from a line of freeholders, or "Franklins," his father inherited a small family estate, which was so deeply mortgaged by his immediate predecessor that it was found necessary to sell it; but by his success in commercial pursuits he was enabled to maintain and educate a family of twelve children, of whom one only died in infancy. The fortunes of his four sons were remarkable, unaided as they were by patronage or great connections. Thomas, the eldest, following the pursuits of his father, acquired the local reputation of an acute and highly honourable man of business, whose intellect gave him much influence with his neighbours, and in a time of threatened invasion, he was mainly instrumental in raising a body of yeomanry cavalry, in which he did the duty of adjutant, and was afterwards chosen to be lieutenant-colonel of a regiment of volunteer infantry. The second son, Sir Willingham, educated at Westminster, was elected to a scholarship of Christ's Church, Oxford, and after gaining an Oriel fellowship, was called to the bar, and died a judge at Madras. James, the third son, having, as cadet, exhibited great proficiency in Hindostanee and Persian, was presented by the India Company with a handsome sword, L.50 in money, and a cornetcy in the First Bengal Native Cavalry, in which he rose to the rank of major. He was noted while in India for his scientific knowledge, which procured him a lucrative civil appointment, but his advancement was interrupted by ill-health, and after executing extensive surveys of the country, he was under the necessity of returning to England, where he died. His collections in natural history were highly appreciated by zoologists.

John, the youngest son, and the subject of this memoir, was destined for the church by his father, who, with this view, had purchased an advowson for him. He received the first rudiments of education at St Ives, and afterwards went to

---

[1] The following is one of his acute remarks on that subject:—"Though there is a general dread of giving too much *power* to our *governors*, I think we are more in danger from the little *obedience* in the *governed*."

[2] Sir Humphry Davy thus elegantly characterizes his scientific labours. "A singular felicity of induction guided all his researches, and by very small means he established very grand truths. The style and manner of his publications on electricity are almost as worthy of admiration as the doctrine they contain. He has endeavoured to remove all bigotry from the subject. He has written equally for the uninitiated and for the philosopher; and he has rendered his details amusing as well as perspicuous, elegant as well as simple. Science appears in his language in a dress wonderfully decorous, the best adapted to display her native loveliness. He has in no instance exhibited that false dignity by which philosophy is kept aloof from common applications; he has sought rather to make her a useful inmate and servant in the common habitations of men, than to preserve her merely as an object of admiration in temples and palaces."

Louth Grammar School where he remained two years; but having employed a holiday in walking twelve miles with a companion to look at the sea, which up to that time he knew only by description, his imagination was so impressed with the grandeur of the scene that former predilections for a sea life were confirmed, and he determined from thenceforth to be a sailor. In the hope of dispelling what he considered to be a boyish fancy, his father sent him on a trial voyage to Lisbon in a merchantman, but finding on his return that his wishes were unchanged, procured him, in the year 1800, an entry on the quarterdeck of the Polyphemus, 74, Captain Lawford; and this ship having led the line in the battle of Copenhagen in 1801, young Franklin had the honour of serving in Nelson's hardest fought action. Having left school at the early age of thirteen, his classical attainments were necessarily small, and at that period there was no opportunity on board a ship of war of remedying the defect. Two months, however, after the action of Copenhagen, he joined the Investigator, discovery-ship, commanded by his relative Captain Flinders, and under the training of that able scientific officer, while employed in exploring and mapping the coasts of Australia, he acquired a correctness of astronomical observation and a skill in surveying which proved of eminent utility in his future career. In the prosecution of this service he gained for life the friendship of the celebrated Robert Brown, naturalist to the expedition. In 1803, the Investigator having been condemned at Port Jackson as unfit for the prosecution of the voyage, Captain Flinders determined to return to England to solicit another ship for the completion of the survey, and Franklin embarked with him on board the Porpoise armed store-ship, Lieutenant-Commander Fowler. In the voyage homewards this ship, and the Cato which accompanied her, were wrecked in the night of the 18th of August, on a coral reef, distant from Sandy Cape, on the main coast of Australia, 63 leagues, and the crews, consisting of 94 persons, remained for 50 days on a narrow sand-bank, not more than 150 fathoms long, and rising only four feet above the water, until Captain Flinders, having made a voyage to Port Jackson, of 250 leagues, in an open boat, along a savage coast, returned to their relief with a ship and two schooners.[1] After this misfortune, Captain Flinders, as is well known, went to the Isle of France, where he was unjustly and ungenerously detained a prisoner by General de Caen, the governor. Meanwhile Franklin proceeded with Lieutenant Fowler to Canton, where he obtained a passage to England in the Earl Camden, East Indiaman, commanded by Sir Nathaniel Dance, commodore of the China fleet of 16 sail. On the 15th of February 1804, Captain Dance had the distinguished honour of repulsing a strong French squadron, led by the redoubted Admiral Linois. Lieutenant Fowler assisted the commodore with his professional advice in this action, and Franklin performed the important duty of signal midshipman. On reaching England, Franklin joined the Bellerophon, 74, and in that ship he was again entrusted with the signals, a duty which he executed with his accustomed coolness and intrepidity in the great battle of Trafalgar, while those stationed around him on the poop fell fast, and were all, with only four or five exceptions, either killed or wounded. In the Bedford, his next ship, he attained the rank of lieutenant, and remaining in her for six years, latterly as first lieutenant, served in the blockade of Flushing, on the coast of Portugal, and in other parts of the world, but chiefly on the Brazil station, whither the Bedford had gone as one of the convoy which conducted the royal family of Portugal to Rio de Janeiro in 1808. In the ill-managed and disastrous attack on New Orleans, he commanded the Bedford's boats in an engagement with the enemy's gun-boats, one of which he boarded and captured, receiving a slight wound in the hand-to-hand fight.

On peace being established, Franklin turned his attention once more to the scientific branch of his profession, as affording scope for his talents, and having made his wishes known to Sir Joseph Banks, who was generally consulted by government on such matters, he set himself sedulously to refresh his knowledge of surveying. In 1818, the discovery of a north-west passage became again, after a long interval, a national object, principally through the suggestions and writings of Sir John Barrow, secretary of the Admiralty, and Lieutenant Franklin was appointed to the Trent, as second to Captain Buchan of the Dorothea, hired vessels equipped for penetrating to the north of Spitzbergen, and, if possible, crossing the Polar Sea by that route. During a heavy storm, both ships were forced to seek for safety by boring into the closely packed ice, in which extremely hazardous operation the Dorothea was so much damaged that her reaching England became doubtful, but the Trent having sustained less injury, Franklin requested to be allowed to prosecute the voyage alone, or under Captain Buchan, who had the power of embarking in the Trent if he chose. The latter, however, declined to leave his officers and men at a time when the ship was almost in a sinking condition, and directed Franklin to convoy him to England. Though success did not attend this voyage, it brought Franklin into personal intercourse with the leading scientific men of London, and they were not slow in ascertaining his peculiar fitness for the command of such an enterprise. His calmness in danger, promptness and fertility of resource, and excellent seamanship, as proved under the trying situation which cut short the late voyage, were borne ample testimony to by the official reports of his commanding officer; but to these characteristics of a British seaman, he added other qualities less common, more especially an ardent desire to promote science for its own sake, and not merely for the distinction which eminence in it confers, together with a love of truth that led him to do full justice to the merits of his subordinate officers, without wishing to claim their discoveries as a captain's right. Added to this, he had a cheerful buoyancy of mind, which, sustained by religious principle of a depth known only to his most intimate friends, was not depressed in the most gloomy times. It was, therefore, with full confidence in his ability and exertions that he was, in 1819, placed in command of an expedition appointed to travel through Rupert's Land to the shores of the Arctic Sea; while Lieutenant Parry, who had in like manner risen from second officer under Sir John Ross to a chief command, was despatched with two vessels to Lancaster Sound, a mission attended with a success that spread his fame throughout the world. At this period, the northern coast of America was known at two isolated points only, viz., the mouth of the Coppermine River, discovered by Hearne, but placed erroneously by him four degrees of latitude too much to the north; and the mouth of the Mackenzie, more correctly laid down by the very able traveller by whose name the river is now known. On the side of Behring's Straits, Cook had penetrated only to Icy Cape, and on the eastern coasts Captain (Sir John) Ross, in 1818, had ascertained the correctness of Baffin's survey, which had been questioned, and had looked into Lancaster Sound and reported it to be closed by an impassable mountain barrier. To stimulate enterprise by rewarding discoverers, the legislature established a scale of premiums graduated by the degrees of longitude to which ships should penetrate, but no provision was made for a pecuniary recompense to any one who should trace out the north-west passage in boats or canoes.

---

[1] The Bridgewater, another merchantman, was also in company with the Porpoise at the time of the wreck, and narrowly escaped sharing the same fate. The master of her, however, having on the following day seen the shipwrecked vessels from a distance, proceeded on his voyage to Bombay, where, on his arrival, he reported their loss. He did not live to explain his motives to those whom he thus deserted, for the Bridgewater never was heard of again after she left Bombay.

Lieutenant Franklin, accompanied by a surgeon, two midshipmen, and a few Orkneymen, embarked for Hudson's Bay, in June 1819, on board of one of the company's ships, which ran ashore on Cape Resolution during a fog on the voyage out, and was saved from foundering by Franklin's nautical skill. On reaching the anchorage off York Factory, a large hole was found in the ship's bottom, but so far closed by a fragment of rock as considerably to diminish the influx of water. Franklin's instructions left the route he was to pursue much to his own judgment; in fact, so little was then known in England of the country through which he was to travel, even by the best informed members of the government, that no detailed directions could be given, and he was to be guided by the information he might be able to collect at York Factory from the Hudson's Bay Company's servants there assembled. No time could be more unpropitious for a journey through that land. For some years an internecine warfare had been carried on between the North-West Company, operating from Canada, claiming a right to the fur trade from priority of discovery, and holding commissions as justices of peace from the colonial government, and the Hudson's Bay Company, which, in virtue of a charter from King Charles the Second, attempted to maintain an exclusive authority over all the vast territory drained by the rivers that fall into the bay. Arrests by clashing warrants of the contending justices were frequent, might became right when the members of the two companies met, personal violence, seizure of property, and even assassination were too common, and in a recent fight at Red River 22 colonists of the Hudson's Bay Company had lost their lives. Numbers also had perished of famine in the interior owing to the contests that were carried on. When the expedition landed at York Factory, they found some of the leading North-West partners prisoners there, and learnt that both companies were arming to the extent of their means for a decisive contest next summer. Such being the state of the country, a party coming out in a Hudson's Bay ship was looked upon with suspicion by the members of the rival company, and it was mainly through Franklin's prudent conduct and conciliating manners that it was permitted to proceed; but sufficient aid to ensure its safety was not afforded by either of the contending bodies. Wintering the first year on the Saskatchewan, the expedition was fed by the Hudson's Bay Company; the second winter was spent on the "barren grounds," the party subsisting on game and fish procured by their own exertions, or purchased from their native neighbours; and in the following summer the expedition descended the Coppermine River, and surveyed a considerable extent of the sea-coast to the eastward, still depending for food on the casual supplies of the chase, and often faring very scantily, or fasting altogether. The disasters attending the return over the barren grounds, on the premature approach of winter, have been told by Franklin himself in a narrative which excited universal interest and commiseration. The loss of Mr Hood, a young officer of very great promise, and who at the time of his death had been promoted to the rank of lieutenant, was especially deplored. The survivors of this expedition travelled from their outset at York Factory down to their return to it again, by land and water, 5550 miles. While engaged on this service, Franklin was promoted to be a Commander, and after his return to England in 1822, he obtained the post rank of Captain, and was elected to be a fellow of the Royal Society. In the succeeding year he married Eleanor,[1] the youngest daughter of William Porden, Esq., an eminent architect, by whom he had a daughter and only child, now the wife of the Rev. John Philip Gell.

In a second expedition, which left home in 1825, he descended the Mackenzie under more favourable auspices, peace having been established throughout the fur-countries under the exclusive government of the Hudson's Bay Company, which had taken the north-west traders into partnership, and was then in a position to afford him effectual assistance, and speed him on his way in comfort. This time the coast line was traced through 37 degrees of longitude from the mouth of the Coppermine River, where his former survey commenced, to nearly the 150th meridian, and approaching within 160 miles of the most easterly point attained by Captain Beechey, who was co-operating with him from Behring's Straits. His exertions were fully appreciated at home and abroad. He was knighted in 1829, received the honorary degree of Doctor of Civil Law from the University of Oxford, was adjudged the gold medal of the Geographical Society of Paris, and was elected in 1846 Correspondent of the Institute of France in the Academy of Sciences. Though the late surveys executed by himself and by a detachment under command of Sir John Richardson comprised one, and within a few miles of two, of the spaces for which a parliamentary reward was offered, the Board of Longitude declined making the award, but a bill was soon afterwards laid before parliament by the secretary of the Admiralty abrogating the reward altogether, on the ground of the discoveries contemplated having been thus effected.[2] In 1828 he married his second wife, Jane, second daughter of John Griffin, Esq.

Sir John's next official employment was on the Mediterranean station, in command of the Rainbow, and his ship soon became proverbial in the squadron for the happiness and comfort of her officers and crew.[3] As an acknowledgment of the essential service he had rendered off Patras in the "war of liberation," he received the Cross of the Redeemer of Greece from King Otho, and after his return to England he was created Knight Commander of the Guelphic order of Hanover.

In 1836 Lord Glenelg offered Sir John the lieutenant-governorship of Antigua, and afterwards of Van Diemen's Land, or Tasmania, which latter he accepted, with the condition that he might be allowed to resign it, if, on a war breaking out, he were tendered the command of a ship. He preferred rising in his own profession to the emoluments of the civil service. In as far as a man of independent political principles, of strict honour and integrity, conspicuous for the benevolence of his character, without private interests to serve, and of a capacity which had been shown in several important commands, was likely to benefit the colony he was sent to govern, the choice was a judicious one, and did honour to Lord Glenelg's discernment. Dr Arnold, no mean judge of character, rejoicing in the promise the appointment gave of a new era in the annals of colonial management, expressed the delight with which, had circumstances permitted, he would have laboured with such a governor in founding a system of general education and religious instruction in that distant land. Sir John's government, which lasted till the end of 1843, was marked by several events of much interest. One of his most popular measures was the opening of the doors of the legislative council to the public, a practice soon afterwards followed by the older colony of New South Wales. He also originated a college, endowing it largely from his private funds with money and lands, in the hope that it would eventually prove the means of affording to all parties secular and religious instruction of the highest kind. At Sir John's request Dr Arnold selected a favourite pupil, the Rev. John Philip Gell,[1] to take the direction of this institution; but much opposition to the fundamental plan of the college was made by various religious bodies, and after Sir John left the colony the exclusive management of it was vested in the Church of England, with free admission to the members of other persuasions. In his time also the colony of Victoria was founded by settlers from Tasmania; and towards its close, transportation to New South Wales having been abolished, the convicts from every part of the British empire were sent to Tasmania. Up to the period of his quitting the government this concentration had occasioned no material inconvenience, neither was there at that time any organized opposition to it. On an increase to the lieutenant-governor's salary being voted by the colonial legislature, Sir John declined to derive any advantage from it personally, while he secured the augmentation to his successor. In 1838 he founded a scientific society at Hobarton (now called the "Royal Society"). Its papers were printed at his expense, and its meetings were held in Government House. He had also the gratification of erecting in South Australia, with the aid of the governor of that colony, a handsome granite obelisk, dedicated and inscribed to the memory of his former commanding officer, Captain Flinders, to whose discoveries we owe our earliest knowledge of that part of the continent of Australia. It stands on a lofty hill, and serves as a landmark to sailors. A magnetic observatory, founded in 1840, at Hobarton, in connection with the head establishment under Colonel Sabine at Woolwich, was an object of constant personal interest to Sir John; and Tasmania being the appointed refitting station of several expeditions of discovery in the Antarctic regions, he enjoyed frequent opportunities of exercising the hospitality he delighted in, and of showing his ardour in promoting the interests of science whenever it lay in his power to do so. The lamented Dumont d'Urville commanded the French expedition, and Sir James Clark Ross the English one, consisting of the Erebus and Terror. The surveying vessels employed in those seas during that period came also in succession to Hobarton—namely, the Beagle, Captain Wickham; the Pelorus, Captain Harding; the Rattlesnake, Captain Owen Stanley; the Beagle (2d voyage), Captain Stokes; and the Fly, Captain Blackwood; all of whom, with the officers under them, received from the lieutenant-governor a brother sailor's welcome. Thus pleasantly occupied, the years allotted to a colonial governorship drew towards a close, and Sir John contemplated with no common satisfaction the advancing strides of the colony in material prosperity; but he was not destined to be spared one of those deep mortifications to which every one is exposed, however upright he may be in his conduct abroad, who is dependent for support and approval on a chief at home that changes with every party revolution. When Sir John was sent to Tasmania, England had not yet recognised as an established fact that the inhabitants of a colony are better judges of their own interests, and more able to manage their own affairs, than a bureaucracy in Downing Street, with a constantly shifting head, ill informed of the factious oligarchies that infest colonies, and of the ties that connect them with subordinate officials at home. Previous to leaving England Sir John was advised, and indeed instructed, to consult the colonial-secretary of Tasmania in all matters of public concern, as being a man of long experience, thoroughly acquainted with the affairs of the colony; and he found, on taking charge of his government, that this was a correct character of the officer next to himself in authority. Mr Montagu was a man eminently skilful in the management of official matters, but he was also the acknowledged head of a party in the colony bound together by family ties, and possessing great local influence from the important and lucrative situations held by its members, and the extensive operations of a bank of which they had the chief control. Party struggles ran high in the legislative council, and the lieutenant-governor's position was one of great delicacy, while the difficulty of his situation was vastly augmented through the practice of the officials in Downing Street of encouraging private communications on public measures from subordinate officers of the colony, and weighing them with the despatches of the lieutenant-governor. For some years, by Sir John's prudent conduct, the harmony of the colonial executive was not interrupted; but at a later period the colonial secretary, having visited England, returned to Tasmania with greater pretensions, and commenced a course of independent action, ever hostile to his chief, subversive of the harmonious co-operation heretofore existing, and thus injurious to the interests of the colony, so that Sir John was under the necessity of suspending this officer from his functions until the pleasure of Lord Stanley, then secretary of state for the colonies, was known. Mr Montagu immediately proceeded to England to state his own case, and he did it with such effect that Lord Stanley, while admitting that the colonial secretary had acquired a local influence which rendered "his restoration to his office highly inexpedient,"[2] penned a despatch which is not unjustly characterized as a consummate piece of special pleading for Mr Montagu, whom it absolves, while it comments on the lieutenant-governor's proceedings in a style exceedingly offensive to a high-minded officer who had acted, as he conceived, with the strictest regard to the public interests. The extraordinary measure was also resorted to of instantly furnishing Mr Montagu, then in attendance at Downing Street, with a copy of this despatch, so that he was enabled to transmit it to Hobarton, where it was exposed in the Bank to public inspection. At the same time there was circulated privately amongst the officers of the colonial government and others a journal of his transactions with the lieutenant-governor, and of his private communications with members of Franklin's family, which he had kept for years while on terms of close social intercourse with them. This volume having answered in England the purpose for which it was intended, was now exhibited in the colony as containing an account of the subjects on which he stated he had held conversations with Lord Stanley. All this took place before the lieutenant-governor received official intimation of Lord Stanley's decision. The recovery of a document which had lain secluded in an office in the colony enabled Sir John afterwards more fully to substantiate one of the most important charges he had made, nevertheless Lord Stanley refused to modify the terms he had employed, or to make any concession calculated to soothe the wounded feeling of an honourable and zealous officer. The arrival of a new lieutenant-governor, the late Sir John Eardley Wilmot, bringing with him the first notice of his own appointment, and consequently finding Sir John still in the colony, served to show more strongly than could otherwise have been done, the hold the latter had gained on the affections of the colonists, and the verdict pronounced on Lord Stanley's despatch by the people, to whom all the merits of the case were most fully known. Sir John, after three months' longer residence at Hobarton as a private individual, waiting for a passage to England, during which time he received addresses emanating from every district of the colony, was attended to the place of embarkation by the most numerous assemblage of all classes of people which had ever been seen on those shores, the recently consecrated Bishop of Tasmania[1] walking at their head, along with the new colonial secretary, the late Mr Bicheno, who for some months had acted in the greatest harmony with Sir John. A local paper, after describing the scene in much detail, adds—"Thus departed from among us as true and upright a governor as ever the destinies of a British colony were entrusted to." Years afterwards, when the enthusiasm of party feelings could have no share in their proceedings, the colonists showed their remembrance of his virtues in a more substantial manner, as will be mentioned below. Sir John, on receiving the secretary of state's despatch, had tendered his resignation, but his successor was appointed before his letter could reach England, though, as we have just said, his recall-despatch did not come to Tasmania till some days after Sir Eardley's arrival.

---

[1] She died in 1825.

[2] Messrs Dease and Simpson of the Hudson's Bay Company, at a later period (1836–1839) completed the survey of 160 miles of coast line, lying between the extreme points of Beechey and Franklin, and navigated the sea eastwards beyond the mouth of Back's Great Fish River, proving the existence of a continuous water-course from Behring's Straits through 73° of longitude, as far eastward as the ninety-fourth meridian.

[3] The sailors, with their usual fondness for epithets, named the ship the "Celestial Rainbow" and "Franklin's Paradise."

---

[1] In later years he became Sir John's son-in-law, as mentioned above.

[2] Lord Stanley's despatch, 13th September 1842. Mr Montagu was promoted to be colonial secretary at the Cape of Good Hope.

Owing to the fortunate rendezvous at Hobarton of the scientific expeditions and surveying ships above named, as well as of many of her Majesty's vessels engaged in the ordinary service of those seas, the intrigues of the family faction and their supporters in the colony being matters of common discussion, became known to numbers of Sir John's brother officers, and a true estimate of the treatment he had received from the colonial minister was formed by the profession to which he belonged. He found, therefore, on reaching England, that the confidence of the Admiralty in his integrity and ability was undiminished, and this was speedily shown by his appointment in 1845 to the command of an expedition, consisting of the Erebus and Terror, fitted out for the further discovery of the north-west passage. With an experienced second in command, Captain Crozier, trained under Parry and James Ross from 1821 in the navigation of icy seas, a select body of officers chosen for their talent and energy, and excellent crews, in ships as strong as art could make them, and well furnished, Franklin sailed from England for the last time on the 26th of May 1845. He was last seen by a whaler on the 26th of July in Baffin's Bay, at which time the expedition was proceeding prosperously. Letters written by him a few days previous to that date were couched in language of cheerful anticipation of success, while those received from his officers expressed their admiration of the seamanlike qualities of their commander, and the happiness they had in serving under him. In autumn 1847 public anxiety began to be manifested for the safety of the discoverers, of whom nothing more had been heard; and searching expedition after expedition despatched in quest of them in 1848 and the succeeding years down to 1854, regardless of cost or hazard, redound to the lasting credit of England. In this pious undertaking Sir John's heroic wife took the lead. Her exertions were unwearied, she exhausted her private funds in sending out auxiliary vessels to quarters not comprised in the public search, and by her pathetic appeals she roused the sympathy of the whole civilized world. France sent her Bellot; the United States of America replied to her calls by manning two searching expeditions, the expenses of which were borne by Mr Grinnel, a wealthy private citizen of great humanity and liberality; and the inhabitants of Tasmania subscribed L.1700, which they transmitted to Lady Franklin as their contribution towards the expense of the search. In August 1850 traces of the missing ships were discovered, and it was ascertained that their first winter had been spent behind Beechey Island, where they had remained at least as late as April 1846. Yet in spite of every exertion by the searching parties, no further tidings were obtained until the spring of 1854, when Dr Rae, then conducting an exploring party of the Hudson's Bay Company, learnt from the Eskimos that in 1850 white men, to the number of about forty, had been seen dragging a boat over the ice near the north shore of King William's Island, and that later in the same season, but before the breaking up of the ice, the bodies of the whole party were found by the natives on a point lying at a short distance to the north-west of Back's Great Fish River, where they had perished from the united effects of cold and famine. These unfortunate men were identified as the remnant of the crews of the Erebus and Terror by numerous articles which the Eskimos had picked up at the place where they perished, many of which Dr Rae purchased from that people and brought to England. Point Ogle is supposed by this gentleman to be the spot where the bodies lie; and this summer (1855) Mr Anderson of the Hudson's Bay Company started from Great Slave Lake to examine the locality, pay the last tribute of respect to the dead, and collect any written papers that might remain there or books and journals said to be in the hands of the Eskimos. By considering the direction in which the party that perished were travelling when seen by the natives, and the small district that remains unexplored, we must come to the conclusion that the ships were finally beset between the 70th and 72d parallels of latitude, and near the 100th meridian. Two entrances from the north may exist to this part of the sea, one along the west coast of North Somerset and Boothia, which is an almost certain one; and the other, which is more conjectural, may occupy the short unexplored space between Captain Sherard Osborn's and Lieutenant Wynniatt's extreme points. To approach this last strait, if it actually exists, Cape Walker would be left on the eastern side of the passing ships. It is a singular and most melancholy fact, that the very limited district of the Arctic Sea thus indicated, and which was specially adverted to in the original plan of search, is almost the only spot that has defied the exertions of the skilful and persevering officers who have attempted to explore it. Sir James Ross failed in reaching it; it intervenes between the extremes of the long and laborious journeys made by Captain Sherard Osborn and Lieutenant Wynniatt. Dr Rae's two attempts to enter it were frustrated by the state of the ice and other circumstances, and Captain Collinson was also stopped short on its southern side by the want of fuel. Lady Franklin had sent out the Prince Albert for the express purpose of searching this quarter, but Mr Kennedy unfortunately, instead of adhering to the letter of his instructions, trusted to a distant view of the passage from the north, which seemed to him to be closed, and turning to the west, made his memorable winter journey through a space which, though he was ignorant of the fact at the time, had been previously examined.

With the utmost economy in its use, fuel would soon become precious on board the Erebus and Terror: and it is probable that after three years one of the ships would be broken up to furnish this essential article. Provisions could not last longer without placing the crews on short allowance, and to do so in that climate subjected them to sure and destructive attacks of scurvy. Fish and venison, it is true, might be procured in quantities sufficient to modify these conclusions, but not to a great extent; and, beyond all question, the numbers of the intrepid sailors who left England in such health and spirits in 1845 had waned sadly by the close of the season for operations in 1849. The forty men seen by the natives early in 1850 were doubtless the only survivors at that date. Franklin, had he lived till then, would have been sixty-four years old, but no one of that age was in the number seen by the natives. Had he been then in existence, he would have taken another route on the abandonment of his ship, as no one knew better than he the fatal result of an attempt to cross that wide expanse of barren ground lying between the mouth of the Great Fish River and the far-distant Hudson's Bay post on the south side of Great Slave Lake. Who can conjecture the reason that turned the steps of the weary wanderers in that direction? Perhaps the desire of solving the long-sought problem of a north-west passage even then animated their emaciated frames, and it is certain that they did solve it, though none of them lived to claim the grateful applause of their countrymen. Later in point of time, and in a higher latitude, Sir Robert M'Clure also filled up a narrow gap between previous discoveries, and so traced out the north-west passage by travelling over ice that has in the five several years in which it has been attempted proved to be a barrier to ships. If ever in the pursuit of whales, or for conveyance of minerals, commercial enterprise endeavours to force a north-west passage by steam, the southern route, whose last link was forged by Franklin's party with their lives, will undoubtingly be chosen. And it is to be deeply regretted that the parliamentary committee in recommending the grant of public money to Sir Robert M'Clure, which his courage and enterprise so well deserved, should have omitted to mention the prior discovery made by the crews of the Erebus and Terror.[1]

---

[1] The erection of Tasmania into a see was promoted by Sir John's exertions and representations.

This sketch of Sir John Franklin's character and public services has been written by one who served long under his command, who during upwards of twenty-five years of close intimacy had his entire confidence, and in times of great difficulty and distress, when all conventional disguise was out of the question, beheld his calmness and unaffected piety. If it has in some passages assumed the appearance of eulogy, it has done so not for the purpose of unduly exalting its subject, but from a firm conviction of the truth of the statements. On the other hand, the writer has abstained, in the only sentences in which it was necessary to speak of opponents, from saying a single word more of their conduct or motives than strict justice to Franklin's memory demanded. Franklin himself was singularly devoid of any vindictive feeling. While he defended his own honour, he would have delighted in showing any kindness in his power to his bitterest foe; and in emulation of that spirit the preceding pages have been penned. (J. R—N.)

FRANKLIN, *Thomas*, the translator of Sophocles and Lucian, was born in London in 1721. He was educated at Westminster School, and afterwards at Cambridge, where he became a fellow of Trinity College, and in 1750 professor of Greek. After taking orders he obtained various minor church appointments, and was at length made chaplain in ordinary to George III. In the intervals of official duty he found time to turn his classical knowledge to account by translating the Epistles of Phalaris, and the whole works of Sophocles and Lucian. His translation of Lucian (in which, however, some of the dialogues are omitted) is the best English version of that classic that has hitherto appeared; that of Sophocles is far from being equally happy. Franklin also wrote a *Dissertation on Ancient Tragedy*, and an *Enquiry into the Astronomy and Anatomy of the Ancients*, besides a variety of minor works, prose and poetical, possessing small literary interest or value. He died in 1784.

FRASCATI, a town of the Papal States, 12 miles S. by E. of Rome, on the declivity of a hill commanding an extensive prospect. The town itself is not in any way remarkable; but the beauty of the vicinity, interspersed with numerous elegant villas, and the salubrity of the atmosphere, annually attract numerous visitors from Rome and other parts. On the summit of the hill, above the town, are the ruins of the ancient Tusculum, the birthplace of Cato, and the favourite residence of Cicero. Frascati took its rise in the 13th century, after the destruction of Tusculum by the Romans in 1191. Many of the older houses date from the 13th and 14th centuries; and the church of San Rocco, formerly the cathedral of San Sebastian, and still called the *Duomo Vecchio*, was built in 1309. The new cathedral was completed in 1700, and contains a monument to Cardinal York, who was Bishop of Frascati, and another erected by the cardinal to his brother Charles Edward, the young pretender, who died here on 31st January 1788. The villa Rufinella, which formerly belonged to Lucien Bonaparte, has within its precincts a hill called "Parnassus," on the slopes of which the names of celebrated ancient and modern authors are planted in box. One of the most splendid of the villas is the Aldobrandini: its grounds are adorned with numerous fountains and water works. Pop. about 5000.

FRASERBURGH, a small but thriving sea-port town of Scotland, Aberdeenshire, on the S. side of Kinnaird's Head, 42 miles N. of Aberdeen. It takes its name from Sir Alex. Fraser of Philorth, who, in 1613, obtained for it a charter as a burgh of regality, and whose representative. Lord Saltoun, is now superior of the town. The same Sir A. Fraser obtained in 1592 a charter for the institution and endowment of a college and university here; and at the west end of the town is a quadrangular tower of three stories, which formed part of the building designed for this seminary. The intention was subsequently abandoned, probably from want of funds. During the last war a large harbour was constructed here as a refuge for British ships of war, which might suffer from stress of weather in the North Sea. It has an area of upwards of six acres, is easy of access, and affords anchorage for vessels of every size. The town is neatly built, nearly in the form of a square, and most of the streets cross each other at right angles. The cross is a fine structure of a hexagonal form, covering an erea of 500 feet, and surmounted by a stone pillar 12 feet high, ornamented by the British arms and the arms of Fraser of Philorth. The herring fishery is actively prosecuted here. Pop. (1851) 3093.

FRATRICELLI, in *Ecclesiastical History*, an enthusiastic sect of Franciscans which arose in Italy about the year 1294. The word is an Italian diminutive, signifying "little brothers," and was used as a term of derision, as most of the sect were apostate monks, whom the Italians call *fratelli*, or *fratricelli*. For this reason the term, as a nickname, was given to many others, such as the Catharists, the Waldenses, and the like, however different in their opinions or in their conduct. But when applied to the austere part of the Franciscans, the name was considered honourable.

The founders were P. Maurato and P. de Fossombroni, who obtained of Pope Celestin V. permission to live in solitude as hermits, and to observe the rule of St Francis in all its rigour. They were joined by various idle vagabond monks, who, living after their own fashion, and making all perfection to consist in poverty, were soon condemned by Pope Boniface VIII. and his successor.

It is said that no less than 2000 persons were burnt by the Inquisition from 1318 to the time of Innocent VI. for their inflexible attachment to the poverty of St Francis. The severities against them were again revived towards the close of the 15th century, by Pope Nicolas V. and his successors. However, all the persecutions which this sect endured were not sufficient to extirpate it; for it subsisted until the times of the Reformation in Germany, when its remaining votaries embraced the doctrine and discipline of Luther.

---

[1] Spars and pieces of rail recognised as having belonged to the Erebus or Terror were picked up by Captain Collinson near his wintering place in Cambridge Bay, and are sufficient evidence of currents setting in that direction, through a passage encumbered doubtless with drift ice.

The very extensive search for this ill-fated expedition has issued in a more complete exploration of those ice-encumbered seas than would otherwise have been instituted; but an account of the operations connected therewith will be given hereafter under the head of "Polar Regions," by one thoroughly acquainted with the whole subject—one who, in the prosecution of daring and successful private enterprise, preceded the modern "arctic voyages" instituted by government, discovered much of the Greenland coast, and gained a higher northern latitude than any former navigator.

FRAUENBURG, a town of Prussia, province of East Prussia, and government of Königsberg, on the Frische Haff. It is only remarkable as having been long the residence of Copernicus, whose tomb is still to be seen in the cathedral, of which he was a canon. The house in which he resided is also shown. Pop. (1849) 2329.

FRAUNHOFER, Joseph von, a distinguished practical optician, was born in 1787 at Straubing in Austria, and died in 1826 at Munich. For a detailed account of his discoveries and mechanical ingenuity, see art. Optics.

FRAUSTADT (Polish *Wschowa*), a town, capital of a cognominal circle in the Prussian government of Posen, 50 miles S.S.W. of the town of that name. It has manufactures of linen and woollen goods, hats, morocco leather, and gloves; and a large trade in corn and cattle. Pop. (1849) 6291.

FREA, or Frigga, or Friga, the wife of Odin, was, next to him, the most revered divinity among the Saxons, Danes, and other northern nations, during the reign of heathenism. As Odin was believed to be the father, Frea was esteemed the mother, of all the other gods. In ancient times, Frea was the same with the goddess Herthus, or Earth, who was so devoutly worshipped by the Angli and other German nations. But when Odin, the conqueror of the north, usurped the honours due only to the true Odin, his wife Frea usurped those which had been formerly paid to mother Earth. She was worshipped as the goddess of love and pleasure, who bestowed on her votaries a variety of delights, particularly happy marriages and easy childbirths. To Frea the sixth day of the week was consecrated, which still bears her name.

FREDERICIA, or Fridericia, a fortified town of Denmark, Jutland, at the northern entrance of the Little Belt. It is named after Frederick III., by whom it was founded in 1615. A toll is collected here on all vessels passing the Little Belt. Pop. (1850) 4326.

FREDERICK, the name of several electors of Brandenburg and kings of Prussia. By far the most remarkable member of the royal family of Prussia is Frederick II., surnamed the Great—the greatest king who in modern times has succeeded by right of birth to a throne. He was the son of Frederick-William I. and Sophia-Dorothea, princess of Hanover, and was born January 24, 1712. His father, Frederick-William, was a man of ill-regulated mind, but possessing considerable administrative ability. He first conceived the idea of gaining for his country, by means of a strong military organization, a place among the great European powers quite out of proportion to its size and internal resources. With this view he maintained, even in times of peace, a force of 60,000 men, whom he trained to a perfection of discipline unknown in Europe since the days of the Roman Republic. He took especial pride in collecting tall soldiers. He had crimps in every capital in Europe to purchase gigantic recruits at prices more than three times the salaries of his best-paid ambassadors. He took equal delight in disciplining them, and indeed seems to have thought that the whole business of life ought to consist in drilling and being drilled. To defray the expenses of this army he was obliged to exercise in the other departments of government a strictness of economy that degenerated into the most sordid avarice. Avarice, however, was one of the most venial of his bad qualities. His nature was essentially bad and coarse, even to brutality. He delighted to make his power felt in the most galling manner, even by the weakest and most harmless of his own subjects. He knew nothing of literature and the fine arts, and utterly despised them both. He banished the celebrated scholar and philosopher Wolf from his dominions, because he ventured to speculate on metaphysics, and almost made up his mind to put an end to the Berlin Academy and the universities. On the other hand, however, he encouraged all the industrial arts, and himself founded some of the richest manufactories, and most famous hospitals and medical colleges, of which Prussia has now to boast. His temper was violent to savageness, and against none was it shown with more ferocious cruelty than the young prince.

The education which the heir-apparent to the throne received from this parent was calculated to make him nothing better than a good drill-serjeant. But he had the good fortune when a boy to be allowed the society of a French lady, whose mother-tongue he speedily picked up; and his first tutor, M. Duhan, succeeded in early imbuing his mind with a love of polite literature. In the society of these persons, and his own mother and sister, Frederick enjoyed a precarious immunity from the tyrannical maltreatment of his father. Reduced at length to despair by the misery of his condition, the young prince determined to fly to England, and seek shelter at the court of his maternal uncle. He communicated his design to the only two friends he ever had, Keith and a young lieutenant by name Katt. The plot was discovered. Keith escaped in safety to Holland. Katt was taken and hung before the eyes of his royal comrade. Frederick himself was only saved from a like fate by the urgent intercession of the emperor of Austria, the kings of Sweden and Poland, and the States of Holland. He was merely confined as a state prisoner in the castle of Custrin, where he was detained till he had nearly completed his twenty-first year. The treatment he had undergone had soured his temper and hardened his heart, but it had also matured his understanding, and made him an adept in the arts of dissimulation. He affected to submit himself in all things to the will of his father; and in 1733, in token of this submission, accepted as a wife at his father's orders the Princess Elizabeth Christina, daughter of Frederick Albrecht, duke of Brunswick Bevern, who was his wife in name only. Till the death of the king in 1740 the favourite residence of the crown-prince was at Rheinsberg, on the frontiers of Mecklenburg. There he surrounded himself with a select literary society, consisting chiefly of Frenchmen, and solaced his leisure hours with his flute, of which he was a perfect master. He also kept up a correspondence with a number of eminent foreign literati, especially with Voltaire, and this correspondence afterwards led to strange results. In his retreat at Rheinsberg Frederick wrote an immense quantity of prose and verse, which he sent to Voltaire to correct and prepare for press. The most notable of these compositions is the *Anti-Machiavel*, a refutation of the *Principe* of the great Florentine diplomatist, in which that policy is condemned with especial severity which the writer pursued from the very day he assumed the Prussian crown. Early in the year 1740 Frederick-William died, and Frederick, who had just entered on his twenty-ninth year, ascended the throne. He found the treasury full, the army in the most perfect discipline, and the commerce and manufactures of the country flourishing and prosperous. The splendid army, which the old king had collected merely for the purpose of looking at, his successor determined to turn to practical account as soon as an opportunity offered. And such a chance was not long of presenting itself. The Pragmatic Sanction had guaranteed Maria Theresa in the peaceful succession to all her father's dominions, and none of the potentates who signed that instrument had been more profuse of his professions to abide by its terms than Frederick. He was now the very first to perjure himself by violating them. Availing himself of the fact that Silesia had originally belonged to the house of Brandenburg, he poured his troops into that province in 1740, and possessed himself of it before his hostile intentions were declared or even suspected. In the following spring the Austrians advanced in force to the relief of such strongholds as still held out. Frederick met them at Mollwitz, and after an obstinate engagement the steadiness and discipline of the Prussian troops carried the day, and the Austrians fled, leaving 8000 men on the field of battle. The victory was not due either to the generalship or personal gallantry of Frederick himself. He had taken command of the cavalry, which had been put to flight early in the action, and, believing that all was lost, had fled with his staff many miles from the scene of action. The victory was really gained by Marshal Schwerin and the Prussian infantry. The success of Frederick tempted the other powers who had had a share in the Pragmatic Sanction to imitate his example, in the hope of profiting like him by the dismemberment of the Austrian empire. The French and Bavarians entered Bohemia, and were joined by the Saxons. Prague was taken; and Frederick, for the second time, inflicted a signal defeat on the Austrian troops at Czaslau, May 17, 1742. By the advice of the English, Maria Theresa resolved to negotiate with Frederick, the most active and dangerous of her enemies. She consented to cede to him Upper and Lower Silesia, and some outlying portions of her wide dominions. Frederick abandoned his allies; Saxony soon followed his example; and the empress-queen, now at liberty to concentrate her forces against the French and Bavarians, speedily drove these invaders across the frontiers. Alarmed, however, at the successes of the Austrians, Frederick once more played the traitor, allied himself with France, and, before his intentions could be guessed, marched through Saxony into Bohemia, took Prague, and threatened Vienna. But he was compelled to retreat as suddenly as he had advanced; but on the 4th of June 1745 he defeated the combined forces of the Austrians and Saxons at Hohenfriedberg in Silesia, and shortly after at Sorr in Bohemia. The result of these victories was to confirm Frederick in the possession of Silesia; while he acknowledged Francis of Lorraine, husband of Maria Theresa, as emperor of Germany. To the second Silesian war, brought to a close by the treaty of Dresden in 1745, succeeded a peace of eleven years. During this interval Frederick was not idle. He reformed and simplified judicial proceedings in all parts of his kingdom, and with the aid of his chancellor Cocceii drew up the Frederician code. He fostered the arts and manufactures as zealously as his own father had done; and though his great military expenditure prevented him from maintaining a navy, yet he secured the right of free navigation for Prussian merchantmen. In the intervals of public business, which he transacted without ministers and with the assistance of only a few clerks, he found time to write a history of the House of Brandenburg, which possesses very considerable literary merit; and a didactic poem on the art of war, which is still highly valued. These, like all his other compositions, are written in French, which language he employed to the utter exclusion of his native tongue. Of German he always spoke with the bitterest contempt, and it has been said that he barely knew enough of that tongue to swear correctly at his grenadiers when they made some false moves on parade. His rigid economy did not prevent him from expending large sums of money in gratifying his taste for architecture; and the splendid palaces of Berlin and Potsdam remain to attest his munificence in this respect. Some of the most splendid buildings in his kingdom were set apart for the accommodation of his troops, which now numbered 160,000 men. This splendid army was not destined to remain long inactive. In the month of August 1756 began the Seven Years' War. The causes that led to it are rather to be sought in the intense aversion and fear with which Frederick was personally regarded by his continental neighbours. Diplomatic skill readily suggested some more specious pretext for deluging Europe with blood. Frederick's agents at the various continental courts made him aware of the storm that was brewing. He saw that he could appeal for help to England alone; and his claims even upon her were none of the strongest. With a prudent temerity he resolved to anticipate his enemies, and strike the first blow. Saxony was overrun with 60,000 Prussian troops; Dresden was taken; Pirna invested; and Marshal Brown, the Austrian commander, who was hastening through Bohemia to its relief, was met by Frederick at Lowositz and utterly defeated. Returning to Pirna, Frederick made himself master of it, and half compelled, half persuaded the Saxon garrison to enlist under his banner. The approach of winter put an end to hostilities; but the advantage of the first campaign lay decidedly with Frederick. Early in 1757 the Prussian troops were marched into Bohemia; and on the 6th May the Austrians under Brown were routed with great slaughter at Prague. Leaving a large force behind him to invest the Bohemian capital, Frederick pushed on to attack the army of Daun, which lay encamped in an almost impregnable position at Kolin. After a protracted and bloody engagement, Frederick was driven back, and compelled to evacuate Bohemia. The position of the Prussian king was at this time desperate. His army had lost its prestige; the members of his own family had begun to lose their confidence in himself; Europe was in arms against him; the English, his only allies, had been defeated by the French at Hastembeck; and his mother, whom he really loved, had just died. His own resolution had nearly given way under these accumulated disasters; and he seriously thought of poison as an escape from his misery. After a short interval, however, his mind recovered its tone, and he was once more steeled against all the reverses of fortune. Collecting his forces once more, he descended like an avalanche upon the combined armies of France and Austria, which he annihilated at Rosbach. Without a moment's delay he flew to Silesia, routed the Austrians, first at Lissa, and still more signally at Leuthen, where he achieved his most glorious victory, recovered Breslau, and expelled the Austrians from Silesia. England marked her sense of Frederick's gallantry by contributing an annual grant of L.700,000 towards the expenses of the war; and this subsidy soon enabled the Prussian king to repair the gaps which his numerous battles made in his ranks. The campaign of 1758 was signalized by a splendid but dearly-bought victory over the Russians at Zorndorf, and by some minor engagements, in which Frederick was less fortunate; and that of the following year by the battle of Kunersdorf, in which, though at first victorious, he was finally defeated with great loss. Berlin next fell into the hands of the enemy, and was only saved from plunder by a heavy ransom. Next spring, however, fortune once more smiled on the Prussian king, who relieved Berlin, and drove the Austrians out of Saxony, after a sanguinary conflict at Torgau. During the winter of that year he repaired his losses as usual, and in spring presented an unbroken front to his many foes. His army, however, was very inferior to what it had been, and his position was hourly becoming more critical. He had actually begun once more to bethink himself of taking poison, when the death of the czarina of Russia, and the accession of Peter III., an enthusiastic admirer of Frederick, completely changed the aspect of affairs. Peace was at once concluded with Russia and Sweden. Being thus freed from his most formidable foes, Frederick was free to concentrate his forces against the Austrians, whom he routed at Buckersdorf, and drove for the last time out of Silesia. Danger now began to menace the house of Hapsburg from another quarter. The Turks had assembled a mighty army on the frontiers of Hungary, and were threatening Vienna; and in February 1763 the peace of Hubertsburg put an end to the Seven Years' War. Frederick yielded nothing. Silesia has ever since his day been an appanage of the Prussian crown.

After an absence of six years, Frederick entered Berlin in triumph. The houses were splendidly illuminated, and the multitude greeted him with acclaim as he rode through the streets. With unremitting energy he set himself to repair the losses and devastation caused by the war. He distributed corn from his own magazines both for seed and food, rebuilt the houses (of which fifteen thousand had been burned to the ground), and apportioned his cavalry and artillery horses among the farmers for the tillage of the soil. Silesia and Pomerania were exempted from all taxes for a certain term of years. The bank of Berlin was instituted, canals were constructed, and manufactories erected with various privileges from the king; and though the true principles of commerce do not seem to have been well understood, he did his best to restore and promote the ruined trade of Prussia.

In 1772 he agreed to the first partition of Poland, and in 1778 incorporated the Franconian principalities, thus making large and valuable accessions to his power. In 1785 he organized the famous "Fürstenbund," which frustrated the attempts of the Austrian emperor to exchange the Low Countries for Bavaria; and in the following year concluded a commercial treaty with the United States of America. Though his career was now drawing to a close, he still bestowed as much time and care on the details of government as he had done in the prime of life, and persisted in this policy till within two days of his death, which happened on the 17th August 1786, after he had entered on the seventy-fifth year of his age, and the forty-seventh of his reign.

Frederick comes before posterity to be judged in the twofold capacity of author and ruler. Even though he had never distinguished himself in the political world, his claims to posthumous renown as a writer would have been entitled to a careful consideration. Some of his compositions we have already alluded to. Though his most elaborate works, they were not such as he prided himself most upon. He believed himself to be a poet, and was as sensitive on the subject of his verses as the humblest poetaster. We have already mentioned Frederick's partiality for everything French. He even adopted the French tongue in preference to his own, and used it as the vehicle of his thoughts in all his works prose and poetical. Like all writers who have written in a tongue of which they have not the full command, Frederick seldom rises above mediocrity in his poetical effusions. Even had he been thorough master of any one form of speech, it is doubtful if he would ever have attained particular distinction as a poet. The "vision and the faculty divine" were not his. He had plenty of wit, chiefly of the satirical kind, and no small abundance of ideas; but he lacked the fancy, the imagination, and the refinement of thought which go to make the real poet. In his prose works he shows to far greater advantage. Besides those formal works which have been already characterized, he wrote a vast number of letters, which have been published among his posthumous writings, and form on the whole the most readable and agreeable of his works. They are always sensible, direct, and concise, and, considering the position of the author, very fair and impartial. Not the least interesting in the collection are those addressed to Voltaire, whom at one time he almost worshipped as a demigod, and at another branded as a knave and rascal. The whole episode, indeed, of Frederick's connection with the patriarch of French literature is one of the most interesting, amusing, and humiliating in the history of letters.

But Frederick the ruler was a very different being from Frederick the author. Except Cromwell, no such governor had appeared in Europe since the days of the old Plantagenets; and in the history of the last two hundred years, no single name stands higher than his, but that of the first Napoleon. Like Napoleon, Frederick in his youth professed himself a warm admirer of constitutional governments, and upheld them as the model of a well-governed state. But he was at heart a tyrant in the old Greek sense of that term, and the single aim of all his policy was to establish a *tyrannis* that should be feared and respected throughout Europe. How successfully he carried out his plan is shown by the results he achieved. The kingdom he received from his father comprised only about 2000 German square miles, and only took rank as a fifth-rate power in Europe. When he died, he bequeathed it to his successor almost doubled in extent, and ranking on equal terms with the oldest and most powerful of the surrounding monarchies. In adapting his means to this end, he was as unscrupulous as a Jesuit. In his proclamations, issued before the Seven Years' War, he paraded, for form's sake, his ancient claims on Silesia; but in his memoirs he coolly describes his real motives when he says, "Ambition, interest, and the desire of making people talk about me carried the day, and I decided for war." The barren glory of military renown was little to his taste unless he saw a fair prospect of securing some solid advantage from the confusion of a general European war; and he always managed to balance his opponents so nicely against each other, that whoever lost he was sure to be a gainer. To say nothing of the strong imprint of his own character which he left upon his nation, the material advantages which his policy secured for it were such as to make Prussia the envy of surrounding nations. Besides the increase of territory already mentioned, Frederick left his successor ten millions sterling in the exchequer, and not a farthing of national debt, an army of 200,000 of the best disciplined troops in the world, and a contented people enjoying wholesome laws and a fairly administered judicial system.

As is often the case with men brought up under the stern rigour of an unreasoning fanaticism, Frederick became in his old age an avowed disbeliever in revelation; and though he was fond of speculating on natural religion, he does not seem to have had any fixed or definite ideas on the subject. His early training had soured his temper as well as blunted his religious sensibilities; and to this must be attributed many of the acts of harshness and cruelty with which he has been taxed, especially in the discipline of his army. The severity of his discipline was such as sometimes led to strange consequences. The royal guard at Potsdam found it so intolerable that they preferred death to life. As, however, by the tenets of their church, suicide was looked upon as an unpardonable sin, they were led to commit what they considered the more venial sin of murder, and always selected as a victim some young and innocent child. They thus gained their object, which was to die without committing suicide. The cases of child-murder by soldiers of the guard became at length so numerous that it was found necessary to devise some means to put a stop to the practice which the punishment had failed to do. The penalty was changed to branding and lashing, and from that day the murders ceased. If, however, Frederick was often guilty of cruelty, the recorded instances of his clemency and generosity are still more numerous and striking.—(*Life of Frederic the Great*, by Lord Dover; *Memoirs of the Court of Prussia*, by Dr Edward Vehse; *Essay on Frederic the Great*, by T. B. Macaulay; &c., &c.)

FREDERICK, a city, capital of a cognominal county in the state of Maryland, North America, stands on the Carroll Creek, a tributary of the Monocacy, 63 miles W.N.W. of Annapolis. It is well and regularly built, and being situated in a rich agricultural district it carries on an extensive trade. It is connected by a branch with the Baltimore and Ohio railway. The public buildings include a courthouse, county jail, market-house, and a college chartered in 1850. Pop. (1850) 6028.

FREDERICKSBORG, a village in the island of Zealand, 20 miles N.N.W. of Copenhagen. It has a castle built in the commencement of the seventeenth century by Christian IV. after a plan of Inigo Jones, and now the usual summer residence of the royal family.

FREDERICKSBURGH, a post-town in the state of Virginia, on the S.W. side of the Rappahannock river, 110 miles above its mouth in Chesapeake Bay, and 60 miles N. of Richmond. The river being thus far navigable, large quantities of tobacco, corn, and flour are exported. Pop. (1850) 4062.

FREDERICKSHALD, or Frederickshall, a maritime town of Norway, stift of Aggerhuus, at the influx of the Tistedaelf into the Idefiord, 57 miles S.S.E. of Christiania. It is noted for its strong castle of Frederickstein, which stands on a perpendicular rock 350 feet high overhanging the sea, and is considered one of the strongest fortresses in Europe. It was at the siege of this fortress that Charles XII., king of Sweden, was killed on 11th December 1718. The town itself is not walled. It was almost totally destroyed by fire in 1759, and has since been rebuilt in a neat and regular manner. Pop. 4000.

FREDERICKTON, the capital of New Brunswick. See New Brunswick.

FREDRO, Maximilian, a celebrated Polish author who died in 1676. He was Palatine of Podolia, and spent his life in the service of his country, in the council as well as in the camp, in both of which he occupied many important posts. His works are written chiefly in Latin, and are full of interesting details both on war and politics; while the vigour and conciseness of his style have procured for him the name of the "Polish Tacitus."

His principal works are—*Proverbs and Counsel, Moral, Political, and Military*, in Polish; *Considerations on the Military Service*, also in Polish; *Vir Consilii Monitis Ethicorum, nec non prudentiæ civilis discendum instructus; Monita Politico-Moralia et Icon ingeniorum; Militarium seu axiomatum belli ad harmoniam togæ accommodatorum libri; Fragmenta Scriptorum togæ et belli.* The first-mentioned work is that upon which chiefly rests the reputation of Fredro, whose thorough knowledge of the world appears in every sentence.

FREE BENCH is that estate which, by the particular custom of the manor, the widow becomes entitled to on the decease of the husband, in his copyhold lands and tenements. Anciently the term was equally applicable to that which the husband becomes entitled to on the decease of the wife; but of later days the estate of the husband has been denominated his *curtesy*, while the term *freebench* has been confined to the widow's estate. (See Watkins on *Copyholds.*)

FREEBOOTERS (Fr. *flibustiers*), a name given to a class of piratical adventurers of all nations, but especially of France and England, who have obtained a place in history by the courage and intrepidity they displayed in executing the most difficult enterprizes. The origin of their history is involved in obscurity, nor has the derivation of their name been precisely determined; but the *flibustiers* of the French historians correspond to the *bucaneers* of our own writers. (See Bucaneers.) The South American islands formed the chief theatre of their exploits; and such was the relentless hostility they exercised against the Spaniards, that during the latter half of the seventeenth century their commerce in those seas was almost utterly ruined. At the commencement of the following century these daring adventurers sustained a series of disasters which sensibly diminished their numbers; and their name, which during a period of fifty years had been so redoubtable and dreaded, ceased to be formidable from that time. The term freebooter has been applied in a general sense to robbers and other plunderers.

FREE CHURCH. See Britain, vol. v., p. 669; and Presbyterianism.

FREEDMAN, a man who has been a slave, and is manumitted. See Libertus, and Slavery.

FREEHOLD, Frank Tenement (*liberum tenementum*), is land or tenement which a man holds in *fee-simple, fee-tail*, or for a term of life. Freehold is of two kinds, in *deed* and in *law*. The first is the real possession of land or tenement in fee, fee-tail, or for life; the other is the right to such land or tenement before entry or seizure.

Freehold is sometimes taken in opposition to villenage. Lambard observes, that land, in the time of the Saxons, was distinguished into *bockland, i.e.* holden by book or writing; and *folkland, i.e.* held without writing: the former was held on far better condition, and by the better sort of tenants, as noblemen and gentlemen, being such as we now call *freehold;* the latter for the most part in possession of peasants, being held by them as *tenants at will.*

FREE IMPERIAL CITIES. This appellation was bestowed, under the German empire, on certain cities which acknowledged no head but the emperor and were governed by their own magistrates. Some of these cities, as Worms and Cologne, acquired various privileges and immunities at an early period, in consequence of the assistance they rendered the emperors in repressing the arrogance of the nobles; and commerce and manufactures gradually contributed to their importance. In this manner the imperial cities originated in the middle of the twelfth century. It would appear, however, that there were free cities in Germany which had existed from the time of the Romans, though possessing little in common with those of later times, and which in the beginning of the sixteenth century lost their most valuable privileges, and even the name of free cities, through the ignorance and carelessness of their magistrates. As to the nature of these privileges it will be sufficient to remark that they were such as to constitute them nothing less than independent republics. The cities of Lombardy, enriched by commerce and encouraged by the popes, often ventured to resist their masters the emperors; and their example was followed by those of Germany. In the middle of the thirteenth century two important confederacies were established for common objects—the Hanseatic League in 1241, and that of the Rhenish cities in 1246. The powerful Hanseatic League lasted nearly 400 years, and its dissolution was effected by several causes in 1630. The remnants of this league, with the former confederacy of cities which had its representatives in the German diet, as well as the free cities of Hamburg, Bremen, and Lubeck were incorporated with the French empire in 1810. As these cities co-operated vigorously in the recovery of German independence, they were acknowledged, together with Francfort, as free cities by the congress of Vienna; and as such they joined the German confederacy, June 8, 1815, and obtained the right of a vote in the diet. (See also Hanse Towns.)

FREEMASONRY. See Masonry, Free.

FREESTONE, sandstone; so called from the facility with which it may be cut or wrought.

FREEWILL Islands, three small islands in the Eastern Seas, discovered by Captain Carteret in 1767, and almost entirely surrounded by a reef, except on the east, where there is a narrow passage that will admit a canoe. Long. 137. 51. E., Lat. 0. 50. S.

FREEZING, and Freezing Mixtures, see Cold, vol. vii., p. 101.

FREIBERG, the mining capital of Saxony, stands on the Münzbach, not far from its confluence with the Mulde, and 19 miles S.W. of Dresden. It is an ancient imperial city, and was long the residence of the Saxon princes, who bestowed upon it many important privileges. The town is well built, paved, and lighted, and is still surrounded by its old walls. It is the seat of the general administration of the mines throughout the kingdom, and owes its rise to the discovery of its silver mines in the twelfth century. Its celebrated academy was founded in 1765, and is frequented by students from all parts of Europe. These are instructed in the practice as well as the theory of mining, and enjoy great facilities for study from the extensive collections of minerals and models, and the library connected with the academy. Among its distinguished scholars it reckons Werner (who was also a professor here), Humboldt, Mohs, and Jameson. The centennial birthday of Werner was celebrated here with great pomp on 25th September 1850. Freiberg has also a high mining school, gymnasium, normal seminary, orphan asylum, theatre, &c. The old castle of *Freudenstein* or *Freistein*, situated in one of its suburbs, is now used as a corn magazine. The cathedral is an elegant Gothic edifice of the fifteenth century—having a richly adorned portal in the Byzantine style, called the *Golden Gate*. It contains numerous monuments, among which is one in memory of Prince Maurice of Saxony, who fell in the battle of Siever-shausen in 1553, and another to Werner, who is interred here. In the Lady Chapel adjoining, are the remains of Henry the Pious and his successors, down to Johann Georg IV. who died in 1694. Freiberg has extensive manufactures of gold and silver lace, woollen cloths, linen and cotton goods, lace, iron, copper, and brass wares, shot, gunpowder, white-lead, &c. It has also several large breweries. In the vicinity are about 130 mines of silver, lead, copper, cobalt, &c., giving employment to upwards of 5000 miners. At Halsbrücke, 3 miles from the town, are extensive smelting works and foundries. Pop. (1849) 14,151.

FREIBURG or FREYBURG, a city in the grand duchy of Baden, capital of the circle of the Upper Rhine, on the Dreisam, and on the Basle and Mannheim railway, 40 miles N. by E. of the former town. The town is generally well-built, having several wide and handsome streets and some squares. Its old fortifications have been replaced by fine public walks and vineyards. It is the seat of an archbishop, and has a Catholic university founded in 1457, with a library of 100,000 volumes, a botanic garden, and a museum of natural history. Among the public buildings are the palaces of the grand duke and the archbishop, the custom-house, exchange, theatre, town-hall, museum, house of correction, &c. The charitable establishments include a foundling hospital, orphan asylum, military hospital, and a blind asylum. The cathedral or minster is considered one of the finest and most perfect specimens of Gothic architecture in Germany, being alike remarkable for the delicate symmetry of its proportions and the good taste of its decorations. It was begun towards the middle of the twelfth century, and was not completed till 160 years afterwards. The tower is 386 feet high, exhibiting a skilful transition from a square base into an octagon, which is surmounted by a pyramidal spire of the most exquisite open-work tracery of stone, of extreme boldness as well as lightness. The edifice is of red sandstone, and contains some stained glass-windows of great beauty, statues of Berchtold V., and other dukes of Zähringen, and paintings by Holbein, Grun, and other artists. In the centre of the square called the fish-market is a fountain surmounted by a statue of Duke Berthold III. of Zähringen, the founder of the city. The manufactures of the town consist of chicory, chemicals, soap, starch, potash, leather, tobacco, and musical instruments. Freiburg was long the capital of the landgraviate of Breisgau. Pop. (1846) 15,380.

FREIBURG, FREYBURG, or FRIBURG, also called Friburg im Uchland, a canton of Switzerland. It is bounded on the N. and E. by the canton of Bern, on the S. and W. by Vaud, and on the N.W. by Lake Neuchâtel. The detached portions are entirely surrounded by the canton of Vaud. Physical features. The canton of Freiburg belongs to the basin of the Aar, and is drained from S. to N. by the river Saane or Sarine, an affluent of the Aar. The southern part of the canton is very mountainous, being covered with offshoots of the Alps which separate the waters falling into the Rhône and Lake Leman from those flowing into the river Aar. The general direction of the surface slope of the canton is towards the N. and N.W. down to the plains skirting the lakes Neuchâtel and Morat, with a small portion declining southwards towards the Lake of Geneva. In the S. or most elevated part of this canton, along the left bank of the Saane, are the Moléson and the Dent de Jaman, on the confines of Vaud, respectively 6710 and 4500 feet above sea-level. On the right bank of the same stream are the Dent de Branleire and Mont Berra, respectively 7740 and 5310 feet high. Rivers. Near the head of the Sanetsch Pass, the most westerly in the Bernese Alps, rises the Saane, which flows N. through the middle of the canton; and on approaching the village of Saanen, turning a few miles W. in Vaud, it resumes its first direction, crosses the canton of Freiburg, flows through the towns of Gruyère and Freiburg, and falls into the Aar below Laupen, after a rapid course of about 72 miles. The valley of Bellegarde expands below Gruyère, where the Charmey joins the Saane as an affluent. Besides the Saane, which drains two-thirds of the canton, there is the Broye, which, flowing northward, and crossing the W. part of the canton, falls into Lake Morat, whence again it issues, and empties itself into Lake Neuchâtel. Climate, soil, &c. From the nature, elevation, and inclination of the surface of Freiburg, as might be expected, the climate is cold in winter, and subject to very sudden changes in spring and autumn. The pasture is excellent, both natural and artificial; and the crops most successfully cultivated are wheat, oats, rye, barley, potatoes, and tobacco in small quantities. Near the lakes of Neuchâtel and Morat, vines and other fruit-trees are cultivated, and forest timber is abundant, and much used as fuel. Animals. The domestic animals are horses, cows, sheep, goats, and pigs, which are not only numerous in proportion to the extent of the canton, but of excellent breeds: the horses and cows are the best breeds in Switzerland. Dairy husbandry is thoroughly understood; and the cheeses made in this canton are the best of their kind. Produce and manufactures. On the banks of the Upper Saane, and in the Charmey valley, are manufactured the cheeses known as Gruyère, of which about 30,000 cwt. are produced every year. Coal is raised in Bellegarde valley, and turf cut on the marshes of Morat. Some small paper-mills, iron-works, and glass-works are in operation; and, besides, there are some inconsiderable manufactures of tobacco, kirschwasser (cherry water), leather, and straw hats. The streams abound with carp, trout, eels, tench, pike, &c.; and of game there are in abundance wild ducks, woodcocks, red partridges, hares, and chamois. Schools. About 200 elementary schools, attended by 8000 pupils, are in active operation, and a normal school for the training of teachers. With the exception of the district of Morat, the Roman Catholic religion is universal over this canton. Since the expulsion of the Jesuits in 1847, there is no reliable information to be had in reference to the college of Freiburg, which was till then under their care, and attended by upwards of 500 students. There is a Protestant college at Morat. Language. The line of demarcation between the French and the German languages passes through this canton, the greater number of the people using the French patois, while the rest speak a very corrupt German dialect. In the upper valley of the Saane the dialect is one of the Romansche language. The educated, however, all speak French.

History. Until the eleventh century the canton of Freiburg formed part of the kingdom of Burgundy; but since that time it was held by the hereditary dukes of Zähringen, one of whom, Berthold IV., built in 1179 the town of Freiburg ("freetown"), on which he conferred a municipal government, thus rendering it independent of the neighbouring feudal lords. After the extinction of the house of Zähringen, this canton passed under the house of Kyburg, and thence to that of Hapsburg, one of whom, Rudolph, the founder of the Austrian dynasty, confirmed and enlarged the liberties of Freiburg in 1274. At that time the territory now called *Alte Landschaft*, "the old country," comprehended the entire canton. In 1450, when Freiburg was assailed by Bern and the other Swiss cantons, the reigning duke, Albrecht of Austria, released the inhabitants from their oath of allegiance, and they remained for some years under the protection of the dukes of Savoy. In 1481, having taken part with the Swiss against Charles the Bold, Freiburg was recompensed by being taken into the confederacy as a sovereign canton or state. By that and the subsequent wars Freiburg has attained its present territorial extent.

Government.

Until December 1830, the government was like that of Bern—a popular municipality. At that date, however, a new constitution was formed, by which all natives of the canton aged 25 years, and being neither servants nor in the service of a foreign state, have the right of voting in the primary assemblies which choose the electors in the proportion of 1 to 100 of the inhabitants. The electors assemble in electoral colleges in the chief town of the district, and elect the members to the great Council of the Canton in the proportion of 1 to 1000 of the inhabitants. The members thus elected are appointed for nine years, and they meet twice a year, in May and November. The Great Council again appoints the Council of State or executive, consisting of 13 members for eight years; and the Court of Appeal, consisting of thirteen judges appointed for life. The president of the Council of State is elected by its members for two years. Freiburg returns five members to the National Council, under the new Swiss constitution, for its federal and general government.

Chief towns.

Besides Freiburg, the capital, the other principal towns are Morat, Bulle, Gruyère, Romont, and Staefs, the inhabitants of which are respectively 1698, 1514, 400, 1400, and 1800. *Morat* (or Murten) on the bank of the Lake of Morat or the Murtenzee, contains a college, a public library, an hospital, an orphan asylum, and a castle built in the thirteenth century. The Lake of Morat is about five miles long by two in breadth, and about 170 feet in depth. *Bulle* is the chief depôt for Gruyère cheese, and stands midway between Freiburg and Vevay, being about nineteen miles from each. *Gruyère* stands at a short distance from Bulle, near the left bank of the Saane or Sarine, and on a hill, of which the top is crowned with a feudal castle, still in good preservation. The area of Freiburg is 566 English square miles, occupied by a population (in 1850) of 99,891, of whom 91,125 were citizens of the canton, 7373 citizens of other cantons, and 1335 foreigners; 87,753 being Roman Catholics, and 12,133 Calvinists inhabiting the district of Morat.

Freiburg, Freyburg, or Friburg, the capital of the canton of Freiburg in Switzerland, is built on several steep hills on both banks of the Sarine, and is thus rendered an extremely striking and picturesque object in the landscape. It lies nearly 16 English miles S.W. of Berne, and 33 N.E. of Lausanne. Intermixed with churches, convents, and other buildings, are green fields, gardens, trees, and naked rocks. The opposite banks of the Sarine are joined by four bridges, of which two are of wood, one of iron, and the fourth an iron suspension-bridge—one of the finest in the world. It is 28 feet wide, 906 long, and 175 feet above the level of the stream. Other remarkable structures are the Lyceum, opened in 1805; the Chancellery, where the Council of State meets and the offices of government are located; the Franciscan Convent, of which Father Girard, promoter of popular education, was an inmate; the town-house, in which the Great Council meets, built in the sixteenth century; the collegiate church of St Nicholas, built in the twelfth century, and famous for its organ and a curious bas-relief of the Last Judgment; the College of St Michael, founded by the Jesuits, by whom several hundred young men are here boarded and educated; and the Ursuline Monastery, which has elementary schools for females. The population of Freiburg is about 9000. Its manufactures are few, the principal being pottery, hardware, leather, tobacco, straw hats, and woollens. There are two printing presses, some dye houses, and sugar refineries. Freiburg has also several libraries, learned societies, a museum, a diocesan school, public baths, a prison, an hospital, and a savings-bank. Saturday is the market-day, and there are five fairs held at stated times throughout the year.

FREIGHT, the hire of a ship, or a part of it, for the conveyance and carriage of goods from one port or place to another; or the sum agreed on between the owner and the merchant for the hire and use of a vessel. It also denotes the cargo itself. See Charter Party.

FREIND, John, a distinguished English physician, was born in 1675 at Croton in Northamptonshire. He made great progress in classical knowledge under Dr Busby at Westminster, and at Christ Church, Oxford, under Dr Aldrich; and while still very young, produced, along with Foulkes, an excellent edition of the speeches of Æschines and Demosthenes on the affair of Ctesiphon. After this he began the study of medicine, and having proved his scientific attainments by various treatises, was appointed professor of chemistry at Oxford in 1704. In the following year he accompanied the English army, under the Earl of Peterborough, into Spain; and on returning home in 1707, wrote an account of the expedition, which attained extraordinary popularity. Two years later he published his *Prelectiones Chimicæ*, which he dedicated to Sir Isaac Newton. In 1722 he entered parliament as member for Launceston in Cornwall, but being suspected of favouring the cause of the exiled Stuarts, he spent half of that year in the Tower. During his imprisonment he conceived the plan of his most important and valuable work, *The History of Physic*, of which the first part appeared in 1725, and the second in the following year. In this latter year he was appointed physician to Queen Caroline, an office which he held till his death in 1728. A complete edition of his Latin works, with a Latin translation of the *History of Physic*, was published in London a few years after his death.

FREINSHEIM, Johann, a distinguished German scholar, was born in 1608 at Ulm in Suabia. He taught rhetoric and belles lettres at Upsal, became librarian to Christina of Sweden, and finally a professor in the university of Heidelberg, where he died in 1660. Freinsheim is best known by his supplement to Livy, which he wrote as a substitute for the lost books of that historian. His imitation of the mere form of Livy's style is very close and sufficiently happy, but as he wanted Livy's other great historical qualities, his "supplement" may rather be regarded as a literary curiosity than a contribution to history. Freinsheim wrote also a supplement to Curtius, and a commentary on that author's works, as also on those of Florus, besides some minor compositions of little value.

FREISING, a town of Bavaria, circle of Isar, on the Isar, 20 miles N.N.E. of Munich. It is a very ancient town, and is said by some to have been founded by the Romans. It was, however, in existence as early as A.D. 444, and was made the seat of a bishop in 724. In 1817 the bishop was transferred to Munich, and raised to an archbishop. Pop. (1845) 5350.

FREJUS, the ancient *Forum Julii*, a town of France, department of Var, about a mile from the Mediterranean, and 15 miles S.E. of Draguinan. It took its name from Julius Cæsar, who is said to have established a Roman colony here. It was improved by Augustus, and in the time of the subsequent emperors it became an important naval station. Among the remains of the ancient town are a triumphal arch, a ruined amphitheatre, traces of two moles which formed the entrance of the port, and portions of a fine aqueduct, which brought the waters of the Saigne into the town from a distance of 20 miles. Traces of its old walls are also visible. The port, which communicated with the sea by means of a canal, has been dried up, and its site is now occupied by gardens. Frejus is the seat of a bishop, and has some handsome modern buildings, among which are the cathedral and the episcopal palace, both of Gothic architecture, and constructed partly of the remains of Roman edifices. At St Raphael, a fishing village about a mile and a half distant, Napoleon disembarked on his return from Egypt in 1799, and re-embarked for Elba in 1814. Pop. about 3000.

FRERE, John Hookham, an accomplished man of letters, and for some years English ambassador in Spain, was author of a light, satirical, and witty poem, the precursor and prototype of Byron's *Beppo* and *Don Juan.* This work, published in 1817, bore the clumsy and unpromising title of "*Prospectus and Specimen of an Intended National Work*, by William and Robert Whistlecraft," &c. The adventures of King Arthur and the knights of the Round Table were the nominal subject of the poem, but its style, formed on that of the Italian poets Pulci and Casti, was its chief attraction. The success of Whistlecraft led to another work in the same vein, *The Monks and the Giants.* In his early days Mr Frere joined his Eton associate Mr Canning in writing for the *Anti-Jacobin* journals. For many years before his death he resided at Malta, in the enjoyment of a handsome diplomatic pension of L.1500 per annum. He died of apoplexy at Malta, January 7, 1846, aged seventy-seven.

FRESCOBALDI, Girolamo, a celebrated Italian organist and musical composer, was a native of Ferrara. The date of his birth is not known. At the age of twenty-three he became organist of St Peter's at Rome. He is regarded as the father of that style now universally employed in all compositions for the organ. Talking of his first work, the *Ricercari e Canzoni Francese fatte sopra diversi obligatis in Partitura*, Dr Burney remarks that it "contains the first compositions we have seen printed in score, and with bars. They are likewise the first regular fugues that we have found upon one subject, or of two subjects carried on at the same time, from the beginning of a movement to the end." Frescobaldi was alive in 1641, but it is not known in what year he died.

FRESCO PAINTING, a method of painting with water-colours on fresh plaster while it is still in a soft state, by which means the colours are incorporated with the plaster, and become as permanent as the material on which they are spread. The Italians, from whom we borrow the term, call it *fresco* (literally *fresh*), either because it is executed upon fresh plaster, or because it is used on walls, alcoves, and other buildings in the open air. Vitruvius (vii. 4) calls it painting *udo tectorio.*

Painting in fresco is a very ancient art. It was practised by the early Greeks, and may be traced even to Egypt. It is generally executed on walls and vaults, the plaster being laid on in successive portions, or so much only at one time as the painter can despatch before it dries. The design is usually drawn previously on paper, to be chalked and transferred to the wall about half-an-hour after the plaster has been laid. From the difficulty of making alterations on the work when the colours are once absorbed, the design should be previously prepared with the greatest accuracy. When an alteration must be made, the part is usually cut entirely away, and relaid with fresh plaster.

The ancients painted on stucco; and we may remark in Vitruvius what infinite care they took in making the incrustation or plastering of their buildings, to render them beautiful and lasting; though the moderns find a plaster of lime and sand preferable for fresco painting, both because it does not dry so hastily, and on account of its subdued and agreeable tint.

The pigments chiefly employed in this kind of painting are earths, because their colours are not liable to be affected by the burning qualities of the lime. White is made of lime slaked some time previously, or of white marble dust; and the other substances used are red and yellow ochre, verditer, lapis-lazuli, black chalk, &c. These only require to be ground and mixed up with water. The brushes and pencils should be long and soft, otherwise they are apt to rake and raise the surface. In order that the work may may come out in all its beauty, the colours must be laid on quickly, while the plaster is still moist; nor should they ever be retouched dry with colours mixed up with the white of egg, size, or gum, as is sometimes done; because such colours grow blackish, and soon tarnish.

FRESHES, in sea language, the increased current of an ebb tide by means of a flood of fresh water flowing out into the sea, by which its waters are often discoloured for a great distance from the coast.

FRESNEL, Augustin-Jean, one of the most eminent philosophers of recent times, distinguished especially by his optical discoveries, was born on the 10th May 1788 at Broglie, in the department of the Eure, and ancient province of Normandy, a portion of France remarkable for the production of able men. His father was an architect, and was in circumstances to give his family a good education. In the case of Augustin Fresnel, who was a younger son, the promise of distinction was, however, at first small. His memory, which never was retentive, refused to be burdened with strange words and grammatical rules. At eight years of age he could scarcely read; yet his peculiar talents were not unjustly appreciated by his young schoolfellows, who used to nickname him "the man of genius;" and his juvenile but systematic experiments on boyish projectiles secured the respect of his companions, while they seemed to indicate the career of an engineer as that adapted to his talents.

At the age of thirteen he entered the "école centrale" of Caen; and at sixteen and a half, the Polytechnic School, where he acquitted himself with distinction, notwithstanding his feeble constitution and already infirm health. From thence he passed to the "Ecole des Ponts et Chaussées," and after the ordinary period of instruction emerged as a civil engineer in the employ of government in the usual manner. The occupations which fall to the care of such young officers in France is not of an elevated or very intellectual character. The selection of road materials, the erection of trivial works, the *surveillance* of subordinates, and the keeping of the public accounts on a small scale; such are their more common duties. Thus Fresnel remained occupied for eight or nine years, during which he exerted his powers in the fulfilment of his daily tasks with that conscientiousness and devotion which distinguished him through life.

On the temporary return of the Bourbons to the throne of France in 1814, he ardently espoused their cause, and exhausted the little physical energy he possessed in military service. The return of Napoleon to power crushed his hopes, and deprived him of his appointments. He was, however, suffered to retire to Paris, where he subsequently received a modest appointment in his own profession at the hands of the reinstated Bourbon government, and where he spent much of his future life.

His first original effort in science was made in 1814. He prepared a paper on the aberration of light, which, though correct, contained nothing new, and it was therefore suppressed. This was a discouragement to him for some time, and indeed his second effort met with a similar repulse. It was on *diffraction*, a class of optical phenomena noticed and discussed a century and a half before by Newton and Grimaldi; and to their writings on the subject the reading of

Fresnel had been confined. The singular and often paradoxical phenomena of shadows, the strange result that when two portions of the same pencil of light fall on the same spot, after passing by an obstacle, they may *interfere*, or produce darkness by their union, was perfectly new to Fresnel, although it had been analyzed and in part explained by Dr Young fifteen or sixteen years before. The principle of "interference" as a peculiar modification of light arising merely from the duplication of lights having the same origin, presented itself to the mind of Fresnel nearly in the form in which it had done to Young, and the result was a paper which, though highly ingenious and original, added little to what was previously known. Not altogether discouraged by this apparent misfortune, he returned to the subject in 1818, and presented to the Institute his celebrated memoir on Diffraction, for which, in the ensuing year, he received the prize of the Academy. This paper was remarkable, in the first place, for having made a real correction on the theory of Young, inasmuch as it explains the forms and colours of shadows and fringes without assuming the very questionable fact of *reflection* from the edges of the diffracting body as having anything to do with the phenomenon of interference. The interference in this case he proved to arise solely from the mixing of the disturbances having their origin at different parts of the front of the wave concerned in producing the final effect; a mode of reasoning which it is the most singular that Dr Young should have overlooked, as it had in some cases been clearly enough anticipated by Huygens.

Fresnel's other great success was in the simultaneous explanation of the connected phenomena of the polarization and double refraction of light *under all circumstances* on the undulatory theory. No doubt he did not reach unaided this great generalization. Dr Young was the first to publish the bold idea of *transverse vibrations*, by which alone it appears possible to account for the transmission with unequal velocities of two impulses through the very same material particles. The date of Young's first written communication of this notion was January 1817. Fresnel states that he had formed the same hypothesis the year before, but, deterred by the difficulty which Arago found in admiting it, did not at that time promulgate his views. It was some years before Fresnel methodically developed the consequences of the unequal elasticity in different directions of vibrating media. In 1821, and the beginning of 1822, he submitted to the Institute a memoir, or succession of memoirs, in which he not only explained the ordinary and extraordinary refraction of Iceland spar, on the supposition that the elasticity of the luminiferous ether is different in a direction parallel to the axis of the crystal, and in a plane at right angles to that direction; but by a geometrical process of great beauty he deduced the consequences of an assumed inequality of elasticity in all three dimensions of the crystal, and showed that the result would be conformable to what had been then but recently discovered respecting crystals with two optical axes. More than this, he gave a remarkable demonstration of the truth of his theory by showing by a direct experiment on topaz, that in this class of crystals neither of the two doubly-refracted rays follows the law of *ordinary* refraction, a conclusion which he had anticipated. The theory, moreover, not only gives an account of the laws of *refraction* of light under these various circumstances, but also of its condition of *polarization*, which again was found to be perfectly conformable to fact.

Owing probably in part to the predominant influence of Laplace in the French Academy (who was entirely devoted to the corpuscular theory of light), these great discoveries were but coldly received in Paris, although warmly supported by all the characteristic energy of Arago. In 1823 Fresnel failed in being elected into the Academy of Sciences. Dulong receiving the vacant place. In his correspondence he expresses himself as mortified by this occurrence, which he attributes to the unpopularity of the undulatory doctrine; but only a few months later (12th May 1823), he was *unanimously* elected an academician, a distinction by no means common. Fresnel's noble memoir on double refraction was not, however, printed in the transactions of the Institute until some years after his death, and the only direct honour which it received was the Rumford Medal of the Royal Society of London, which was delivered to Fresnel very shortly before his decease.

In Dr Peacock's life, and miscellaneous works of Dr Thomas Young, may be found part of the interesting correspondence of that great man with Fresnel during his later years. They throw light on the origin and course of some of Fresnel's discoveries, and bear a pleasing testimony to the honourable frankness which characterized the intercourse of those illustrious rivals.

Of Fresnel's other discoveries connected with the theory of light, we cannot here particularly speak. The most remarkable, perhaps, were the photometrical estimate of the intensity of reflected light, and that on the changes produced in the condition of polarized light by total reflection in glass. It will be seen by the list of papers at the close of this article that the number of optical papers which Fresnel wrote between 1817 and 1823 was very considerable.

We have now to mention a practical application of optics to the useful arts with which the name of Fresnel will ever be honourably associated. At least as early as 1819 it occurred to him that lenses might be substituted for mirrors, for the purpose of directing parallel rays of light from lighthouses, and thus preventing in a great measure the natural weakness, in consequence of its divergence, of light seen at a distance. It farther occurred to him that lenses of large size, and of moderate thickness, might be *built up* of segments of lenses. This last idea was not indeed new, for Buffon had proposed to diminish the weight and thickness of lenses by grinding them into zones which should have a common focus; and Condorcet proposed to construct these zones of separate segments. Sir David Brewster suggested in 1811 a similar construction, unaware, it appears, of what Condorcet had written. But all of these writers described their contrivances as applicable to burning instruments for concentrating the solar rays. Fresnel appears to have been unaware of what his predecessors suggested, but he has the far greater merit of actually applying the suggestion to the important purpose of lighthouse illumination. It was first carried into effect in France, where *polyzonal lenses* were made by M. Soleil, and have gradually been introduced into other countries, first into Holland, and then into Scotland. (See article LIGHTHOUSES.) Not content with this great improvement, Fresnel exerted remarkable ingenuity in contriving farther improvements in the mode of distributing light for the purposes of navigation under almost every conceivable circumstance; and he made copious use of the principle of the total reflection of light in glass, which had never before been applied to such purposes. In 1819 he was nominated upon the lighthouse commission; and in July 1823 the Corduan Lighthouse, at the mouth of the Garonne, was completed upon the new plan.

Of the last days of Fresnel little remains to be said. His constantly feeble frame at last became a prey to consumption. The duty of examiner of the Polytechnic School, which he had unwisely undertaken, gave a fatal turn to his malady. According to Arago, the government of the day refused him, on political grounds, a vacant post more suitable to his enfeebled state. Highly esteemed and admired by a few real friends, his optical discoveries remained under the check of the adverse dominant party of the Academy of Sciences. Some of his best memoirs were not printed in his lifetime. The greatest honour of his life came from

Fresnel.

England; first his election as a foreign member of the Royal Society in 1825, and secondly, the award by the same body of the Rumford Medal in 1827.[1] This last token of worldly praise was conveyed by Arago to the death-bed of Fresnel, at Ville d'Avray, near Paris, who has given this touching account of his sad mission:—"His strength, then almost exhausted, scarcely permitted him to glance at this token, so rarely awarded, of the esteem of the illustrious society. All his thoughts turned upon his approaching end; 'I thank you,' he said in a subdued voice, 'for having accepted this commission; I know the pain it must give you, for you feel, I am sure, that the fairest wreath is but insignificant when we must lay it on the grave of a friend.'"[2]

Fresnel died at Ville d'Avray on the 14th July 1827.

The following is believed to be a complete list of Fresnel's published writings, which has been obligingly communicated to the writer of this article by M. Léonor Fresnel, the brother and nearest surviving relative of Augustin Fresnel. They are enumerated in the order in which they were written, or at least read to the Institute or Philomathic Society.

1. First Memoir on the Diffraction of Light; and Supplement. Read 23d October 1815 and 15th July 1816. *Annales de Chimie*, 2d Series, i. p. 239. 2. Letter to M. Arago on the influence of Heat on the Colours of Crystallized Plates. *Ann. de Ch.*, 2d Series, iv. 298. 3. Memoir on the modifications which Reflection induces in Polarized Light; and Supplement. Read 24th November 1817 and January 1819. *Bulletin de la Société Philomatique*, February and March 1823. 4. Memoir on the Colours developed by homogeneous fluids in Polarized Light. Read 30th March 1818. First published in 1846 in the *Memoirs of the French Academy*; also in *Ann. de Ch.*, 3d Series, xvii. 172. On the rotatory property of Oil of Turpentine, &c., discovered by Seebeck. 5. Letter to M. Arago on the influence of the Earth's motion on some optical phenomena; and additional Note. *Ann. de Ch.*, 2d. Series, ix. 56 and 286. 6. Memoir on the mutual action of the Rays of Polarized Light. Conjoint Memoir with Arago. *Ann. de Ch.*, 2d Series, x. 288. Shows, amongst other things, that oppositely polarized rays do not interfere. 7. Memoir (second) on the Diffraction of Light. Read 29th July 1818. *Mem. Instit.*, vol. v.; *Ann. de Ch.*, 2d Series, xi. 246,—the celebrated Memoir which received the Prize. 8. Memoir on the Reflection of Light. Read 15th November 1819. *Mem. Inst.*, 1846. *Ann. de. Ch.*, 2d Series, xv. 379; and 3d Series, xvii. 316. 9. Note on the attempts to decompose Water by means of a Magnet. *Ann. de Ch.*, 2d Series, xv. 219. 10. Note on the Burners of Lamps with concentric wicks. *Ann. de Ch.*, 2d Series, xvi. 377. In connection with his optical inventions for Lighthouses. 11. On the calculation of the Polarized Tints of Crystallized Plates. *Ann. de Ch.*, 2d Series, xvii. 102. And further notes on the same subject, with answer to M. Biot, pp. 167, 312, 393, of the same volume. 12. Note on the Laws of Refraction in Crystals with one and two axes. *Moniteur* Journal, 12th December 1821. 13. Memoir on Double Refraction. Read 26th November 1821, and 22d January and 1st April 1822. *Mem. Instit.*, vol. vii., Contains the celebrated mechanical theory of Double Refraction in Crystals of one and two axes. Translated in Taylor's *Scientific Memoirs*, vol. v. 14. "On Light;" in the supplement to the French translation of Thomson's Chemistry. Paris, 1822. Contains an excellent elementary view of the Undulatory Theory. 15. Note on the Double Refraction of Compressed Glass. *Ann. de Ch.*, 2d Series, xx. 376. 16. Explanation of Refraction on the Theory of Waves. *Ann. de Ch.*, 2d series, xxi. 225, and *Bull. Philom.*, October 1821. 17. Memoir on a new system of Lighthouses (July 1822). Published by the Board of *Ponts et Chaussées*. 18. On the Ascent of Clouds in the Atmosphere. *Ann. de Ch.*, 2d Series, xxi. 260. 19. Answer to a Letter by M. Poisson. *Ann. de Ch.*, 2d Series, xxiii., 32 and 113. 20. On the Phenomenon of Coloured Rings. *Ann. de Ch.* xxiii. 129. 21. On the Double Refraction of Light passing through Rock Crystal parallel to the axis. Read 9th December 1822. *Ann. de Ch.*, 2d Series, xxviii. 147; and *Bull. Philom.*, December 1822. 22. On the Modifications produced by Reflection on Polarized Light. Read 7th January 1823. *Ann. de Ch.*, 2d Series, xxix. 175 (*extract*), and xlvi. 225. Contains the theory of Circular Polarization after plain Polarized Light has been twice totally reflected within glass. 23. Theoretical considerations on the Polarization of Light. *Bulletin Philomatique*, October 1824. 24. Note on the repulsion exerted by heated bodies upon one another. *Ann de Ch.*, 2d Series, xxix. 57 and 107; and *Bull. Philom.*, June 1825. Fresnel also published some observations "on the principal objections of Newton to the system of luminous vibrations, and on the difficulties presented by his hypothesis of *fits*" in Ferussac's Revue Encyclopedique, February 1823. It is much to be desired that these scattered writings of Fresnel were collected in a uniform manner. Some further account of Fresnel's optical discoveries will be found in the Sixth Dissertation prefixed to this Encyclopædia, chap. v. (J. D. F.)

Fresnoy
||
Friars Observant.

FRESNOY, Charles Alphonse du, a French painter and writer on art, was born at Paris in 1611. His father, who was an apothecary, intended him for the medical profession, and educated him with that view. Contrary to the wishes of this parent, Du Fresnoy began the study of art, and having gone to Rome to perfect himself, was reduced to great straits, from being compelled to procure his own subsistence. The arrival of his old fellow-student Mignard at length enabled him to prosecute his studies in peace, and the two artists now spent all their time in copying the great masterpieces of the Farnese gallery. In 1656 Du Fresnoy returned to France, where he remained till his death in 1665. His pictures, which are not very numerous, are more remarkable for correctness of drawing and colour than force or originality of conception, and would never of themselves have preserved Du Fresnoy's name. His poem *De Arte Graphica* is the work by which he is best known. It is written in Latin verse, and has had the good fortune to be translated into most of the European tongues. There are three English versions of it; one in prose by Dryden; the second in verse by Wills, himself an artist; and the third, by Mason, in rhyme. A sort of factitious interest centres in this last version, which was annotated by Sir Joshua Reynolds. The work itself, which is a sort of critical treatise on the practice of painting, is dry, and scarcely relieved by even an occasional gleam of sentiment or fancy.

FRET, or Frette, a kind of architectural ornament, consisting of one or more fillets that meet in vertical and horizontal directions, as in the embattled and lozenge mouldings. Also a knot composed of two lists, or small fillets interlaced, used as an enrichment in empty spaces, chiefly in plastered roofs.

FREUDENSTADT, a town of Würtemberg, circle of the Black Forest, on the right bank of the Murg, 42 miles W.S.W. of Stuttgard. It has manufactures of woollen cloth, nails, white-lead, potash, and Prussian blue; and some trade in corn, cattle, and wood. Pop. 4100.

FREUDENTHAL, a town of Austrian Silesia, circle of Troppau, on the Black Water, 22 miles W. of Troppau. It has a large castle, a Piarist college, orphan asylum, and manufactures of linen and woollen cloths. Pop. 3600.

*FREY, Joachim, an eminent Swiss engraver. See vol. viii., p. 807.

FRIAR (Lat. *frater*; Ital. *fra*; Span. *frayle* or *fray*; Fr. *frère*; Celt. *brair* or *vrair*; *i.e.* brother), an appellation common to monks of every order, but more particularly applied to those of the mendicant orders, of which the principal were the four following; 1. minors, grey friars, or Franciscans; 2. Augustines; 3. Dominicans, or black friars; 4. Carmelites, or white friars. The name is restricted to such monks as are not priests, the latter being usually dignified with the appellation of *father*.

Friars Observant (*fratres observantes*), a branch of the Franciscans who separated from the brethren of their order on the ground of a laxity of discipline, and lived apart in places of their own choosing, simply agreeing among

---

[1] Chiefly at the instance of Sir John Herschel, as we learn from Dr Young's correspondence (*Misc. Works*, vol. i., p. 400). Young, speaking of himself, characteristically says, "I was obliged to be silent from being *too much* interested in the subject;" and in another letter to Fresnel himself, "I should also claim some right to participate in the compliment which is tacitly paid to myself in common with you by this adjudication; but considering that more than a quarter of a century is past since my principal experiments were made, I can only feel a sort of anticipation of *posthumous* fame which I have never particularly coveted."

[2] Arago, *Eloge de Fresnel*, Œuvres, tom. i.

Friction

Societies.

themselves to observe the rules of their order more strictly than the conventuals did.

FRICTION, in *Mechanics*, denotes the resistance which a moving body meets with from the surface on which it moves. Friction arises from the roughness or asperity of the surface of the body moved on and that of the body moving; for such surfaces consisting alternately of eminences and cavities, either the eminences of the one must be raised over those of the other, or they must be both broken and worn off; but neither can happen without motion, nor can motion be produced without a force impressed. Hence the force applied to move the body is either wholly or partly spent on this effect; and consequently there arises a resistance or friction, which will be greater, *cæteris paribus*, according as the eminences are the greater and the substance the harder; and as the body, by continual friction, becomes more and more polished, the friction diminishes. See MECHANICS.

FRIDAY, the sixth day of the week, so named from the Scandinavian goddess Frea or Friga, the wife of Odin. By the Romans it was called *dies Veneris*.

FRIDSTOL. Among the immunities granted to churches in ancient times, mention is made of the *fridstol*, *i.e.* "the seat of peace," or sanctuary, where criminals might find safety and protection. Of these there were many in England; the most celebrated of which were that at Beverley, and that in St Peter's church at York, granted by charter of Henry I.

FRIEDLAND, a town in the province of East Prussia, government of Königsberg, and 27 miles S.E. of the town of that name. Here on 14th June 1807 the French defeated the allied forces of Russia and Prussia. There are several other towns in Germany of this name.

FRIENDLY ISLANDS. See POLYNESIA.

FRIENDLY SOCIETIES are associations of persons chiefly in the humbler classes for the purpose of making provision by mutual contribution against those contingencies in human life, the occurrence of which can be calculated by way of average. The principal objects contemplated by such societies are the following:—the insuring of a sum of money to be paid on the birth of a member's child or on the death of a member or any of his family; the maintenance of members in old age and widowhood; the administration of relief to members incapacitated for labour by sickness or accident, and the endowment of members or their nominees. Friendly societies are therefore associations for mutual assurance, but are distinguished from assurance societies, properly so called, by the circumstance that the sums of money which they insure are comparatively small.

bjects
such
cieties;

eir
story;

Although the period when such societies originated appears to be unknown, their existence in ancient times is unquestionable. They were numerous in England among the Anglo-Saxons, but from the general want of learning at so early an age, and the difficulty of preserving written documents even of the highest importance relating to a period so remote, it cannot be expected we should now possess any very complete records of their history or proceedings. Writers of credit, however, have mentioned several of these fraternities or "gilds" as existing both before and subsequently to the Norman Conquest, and their rules which are still preserved are highly interesting from their similarity to those of the friendly societies of the present day.[1] "These guilds or social corporations," observes an excellent writer, "seem on the whole to have been friendly associations made for mutual aid and contribution to meet the peculiar exigencies which were perpetually arising from burials, legal exactions, penal mulcts, and other payments and compensations."[2] Some of them had for their objects the bestowal of annual charity, the payment of stipends to poor persons, the entertainment of poor strangers and travellers, and various other works of a like charitable and benevolent character. It is highly probable that, notwithstanding the inconveniences arising from the political and social disturbances so frequent in England during the middle ages, the formation of the institutions in question suffered no permanent interruption.

Friendly
Societies.

No general account of their proceedings, however, is attainable. Their operations were confined to certain localities; they were formed for limited periods, after which they ceased and were reconstructed, and the only records of their labours consisted of their accounts, and perhaps a few scanty and ill-kept minutes, all of which were cast aside as without value on the dissolution of the body to which they referred. Even one of the most ancient friendly societies in London, which is said to have been founded in 1715, and to have continued from that period, possesses no documents from which may be gathered either its own history or that of any kindred institutions.[3]

their importance

to individual members,

It is scarcely possible to overrate the importance of such associations. When founded on correct principles and conducted with prudence, they are in every point of view of the highest value, not only to that class of society for whose welfare they are more immediately designed, but to the community in general, of which that class is a component part. A labouring man with a family to provide for is, as a general rule, unable, even with his utmost industry and frugality, to make a sufficient provision against a time of necessity; but as a member of a friendly society he can with comparative facility accomplish this desirable object, and without subjecting himself or those who are dear to him to any severe privations, he is enabled to look forward to substantial and adequate aid in the event of sickness or other unavoidable evils of a natural kind. But the benefits he secures by this means are of a moral and intellectual, as well as a merely physical character; the allowances which he receives are not accompanied by the painful reflection that they are the fruits either of public or of private charity; they are accepted by him as the legitimate produce of his own labour and foresight. Such considerations cannot but administer great comfort to a sufferer accustomed during an active life to cherish the sentiments of independence and self-reliance. The very self-denial requisite to secure the benefits of a friendly society is not only itself a virtue, but is in its exercise directly instrumental to moral and intellectual advancement. A man who acts on such principles must necessarily be more amiable and more intelligent than those who overlook them: he must be a better husband, a better father, a better servant; and this is amply illustrated by the observations of those who have had most experience of friendly societies, and who affirm that members of these bodies are not only the most intelligent but the most trustworthy of their class. It is scarcely necessary to remark that the influence of friendly societies upon the community in general must be eminently beneficial. By fostering habits of frugality, self-reliance, and independence, they restrain the tendency too common among the labouring classes to rely on parochial relief rather than their own exertions, and thus they counteract one of the most active causes of the moral deterioration of the people, while their direct effect is to diminish the burdens laid upon parishes for the support of the poor.

and to society in general.

It is unnecessary to encumber the present article with the

Principles of computation adopted.

---

[1] Some of these institutions among the Saxons are referred to in Hick's *Thesaurus*, and in particular those at Cambridge and Exeter, of which the rules are fully given; other institutions of the same character are referred to as existing after the Conquest, by Dugdale, in his *Monasticon*. The laws of St Catharine's guild at Coventry in the reign of Edward III. are cited by that author at length, as "manifesting the decent government, ceremony, devotion, charity, and amity of those times."

numerous and various tables which from time to time have been constructed to regulate the computations of friendly societies. It will be sufficient to notice, in general terms, the principles on which such computations are based, and in accordance with which those tables are constructed; these principles are derived from the operation of interest and annuities, and from the doctrine of probability. The former, *i. e.* the operation of interest and annuities, affords the means of ascertaining what present or periodical payments would increase to given sums in future specific periods when such sums might be required to have been created or realized; the latter, *i. e.* the doctrine of probability, renders it easy to determine the measure of the expectation of some supposed future event happening or not happening, such as sickness; and if the event must occur at one time or other, such as the event of death, it furnishes the means of determining the time at which, on an average, it may be expected to occur. The tables computed on these principles, it need scarcely be added, are large and numerous, as well as of the utmost practical importance.

Progress of friendly societies.

That the progress of friendly societies in Britain has been extremely great is beyond doubt, and that such progress is in the highest degree honourable to the industrious classes is no less unquestionable. It is however impossible to discover the number of societies which have been in existence. It has been stated that from January 1793 to January 1832, a period of thirty-nine years, there existed in Great Britain and Ireland 19,783 such societies, and that of these 16,596 were in England, 769 in Wales, 2144 in Scotland, and 274 in Ireland. It has further been stated that in the year 1815 the number of members amounted to 925,429.[1] Mr M'Culloch hesitates to admit the accuracy of this statement; and in the report of the House of Commons, dated November 29, 1852, p. 12, it is expressly stated that "there is no authentic account of the number of friendly societies enrolled previous to the 19th June 1828." The same report further declares that "it is almost impossible to ascertain the number of friendly societies which are now in existence;" it furnishes, however, a table prepared from returns sent to the Registrar of Friendly Societies which exhibits the number of those societies certified in England and Wales between the years 1828 and 1847. From this table the following results appear:—

Number of societies certified in England from 1828 to 1847,	9497
Number of members of such societies on 8th July 1847,	740,581
Amount received from members during the year preceding 8th July 1847, . . .	£662,082
Amount paid to or on account of members during the year preceding 8th July 1847, . .	£491,462
Number of societies certified in Wales from 1828 to 1847,	936
Number of members on 8th July 1847, . .	41,141
Amount received from members during the year preceding 8th July 1847, . . .	£31,669
Amount paid to members or on their account for the year preceding 8th July 1847, . .	£27,516

From the view thus given upon unquestionable authority, it appears that the aggregate number of persons who on a given day in 1847 were members of friendly societies in England and Wales alone was 781,722; that the sums contributed by them in one year amounted nearly to L.700,000, and that the amount distributed among them in one year was considerably more than half a million sterling. It must be recollected also that the table from which the above extracts are taken refers only to certified societies, and that there existed, as there still exist, a large number of uncertified societies possessing a very large number of members and a very large amount of revenue. It may be proper further to add, that according to the same authority, the number of societies in England and Wales which have been certified from the 19th June 1829 to the 30th September 1852 amounts to 16,000. These figures must necessarily exhibit to the reader a striking view of the progress of the societies in question, and suggest some idea of the vast amount of good of which they have been the instruments.

Importance of a sound constitution to their success.

Great, however, as the progress of friendly societies has been during the last fifty years, and vast as the benefits are which have resulted to individuals and society from their labours, their beneficial effects have on various occasions been in no small degree counteracted by injurious causes, and in particular by defects and errors of constitution, and by the imprudence or misconduct of those under whose management their pecuniary affairs have been placed. Without entering on minute detail as to the former of the two causes of miscarriage now mentioned, we shall refer only to one illustration of the injurious effects resulting from it, and as evinced by the practice adopted by some societies of making their allowances at the outset of their career on too liberal a scale. This, although a natural error, was in more than one instance productive of the most fatal consequences. It is obvious that an association formed of members in the prime of life and in vigorous health, could not be called upon for any great outlay for some years after its institution, the amount of sickness or incapacity for labour among its members being comparatively small. Under such circumstances there is a rapid accumulation of funds, and the flourishing state of their finances naturally leads the members to presume that they may with perfect safety make very considerable allowances to the few who require relief. The fact is wholly overlooked, that if the society shall continue to exist, a time must arrive when a large majority of its members must necessarily require assistance, and that liberal allowances at the outset are altogether inconsistent with the demand thus to arise. From this fundamental error the most fatal consequences have been produced. Not only have societies, which at their commencement appeared in the most flourishing state, become bankrupt, but aged members, after contributing for a long series of years to the common fund, have found themselves in their old age deprived of that support for which in the season of youth and vigour they had with so much self-denial and frugality sought to provide.

Legislative enactments.

From these remarks as to the importance on the one hand of friendly societies, and on the other as to the dangers to which they are exposed, it must be sufficiently obvious that they possess a strong claim upon the fostering care of government. It was not, however, till the year 1773 that the attention of parliament was awakened to the wisdom of efficiently protecting and encouraging institutions which, under legislative regulations, have since that period conferred so large an amount of benefit on a most important part of the community. In that year a bill was introduced into parliament, the object of which was to empower parishes in England and Wales to grant annuities to persons willing to purchase them at a price set down in tables annexed to the bill, which annuities were, if necessary, to be chargeable upon the poor's-rates, as a collateral security to the purchasers. This bill having passed the Commons was rejected in the Upper House. Another bill was introduced in 1789, which in like manner having been approved of in the Lower House was thrown out in the House of Lords. No legislative interference, therefore, as to friendly societies occurred until 1793, when an act was passed which is known by the name of its author, Mr George Rose. Of the provisions of this bill the following is a brief abstract. The act recited "that the protection and encouragement of friendly societies in this kingdom, for securing by the voluntary subscription of the members thereof separate funds for the mutual relief and maintenance of the said members in sickness, old age,

Act of 1773.

riendly ocieties.

ovisions Mr ose's act.

and infirmity, is likely to be attended with very beneficial effects by promoting the happiness of individuals, and at the same time diminishing the public burdens. It then proceeded to enact that it should be lawful to institute such societies for the purposes above mentioned, and for the members of such societies to meet in committee to make rules and regulations for their guidance, to impose fines and forfeitures upon those violating such rules, and to amend those rules from time to time. The act further provided that no society should come within the meaning of the act until its rules should be exhibited to the justices in quarter sessions and approved of by them. These rules were not to be afterwards altered otherwise than by three-fourths of the members present at a general meeting, or by three-fourths of a committee appointed to manage the concerns of the society. The act further provided that, before the enrolment of its rules, each society should declare the intents and purposes for which it was established; and that it should be unlawful to dissolve any such society so long as any of its purposes remained to be carried into effect, and that it should be unlawful for the society to make any use of its funds, other than that declared to be the purpose of its establishment.

rivileges onferred y it.

In addition to those restrictions, the act conferred certain privileges on friendly societies, which may be briefly stated as follows:—1. Any bonds required from the officers of the society were to be given to the clerk of the peace without fee or reward, and were not to be liable to stamp duty. 2. In case of neglect in the treasurer or other officers in rendering their accounts, summary proceedings were made lawful before the supreme judicatories of the country, and that such proceedings should be taken without any expenses charged by such judicatories, and that counsel should be assigned to the society, who should perform his duty in advocating their interests without fee or reward. 3. That the money of the society in the hands of a treasurer should on his decease have a preference over all his other debts. 4. That the officers of the society should be invested with the power of "suing and being sued." 5. That a member, thinking himself aggrieved, should be allowed to take summary proceedings before two justices. 6. That if the rules of a society provided for an arbitrator, there should be no appeal from his decision; and finally, that no member of a friendly society was to be removed from any parish until he should become actually chargeable.

ubsequent tatutes.

Such were the provisions of Mr Rose's act. Since the year in which it was passed, several additional statutes have been enacted for the purpose of securing and promoting the interests of friendly societies. The principal acts in existence up to the present year (1855) are the following seven, viz.:—33d Geo. III., cap. 54; 59th Geo. III., cap. 128; 10th Geo. IV., cap. 56; 4th and 5th Will. IV., cap. 40; 9th and 10th Vict., cap. 27; 13th and 14th Vict., cap. 115, and 15th and 16th Vict., cap. 65. There are a few others relating to minor points, which however it is unnecessary to specify.

Recent enactments.

In the course of the year 1854, a very important bill was introduced into the House of Commons, entitled "A Bill to consolidate and amend the law relating to Friendly Societies." A select committee of the house was appointed, who, after carefully investigating the subject and considering the bill, presented their report. This document pointed out in the clearest manner the necessity of legislation on the subject, and made a variety of important suggestions as to the bill referred to. We shall now present the reader with an outline of the principal provisions of the bill itself, which is entitled "A Bill to consolidate and amend the law relating to Friendly Societies."

Report of elect committee, 1854.

Friendly Societies Bill of 1855,

The preamble sets forth that "it would conduce to the improvement of the law relating to friendly societies, if the several statutes relating thereto were consolidated, and certain additions and alterations were made therein." The first clause repeals all the preceding statutes with certain exceptions as to existing societies, and subsequent clauses provide that societies instituted prior to this act shall continue, and their rules, contracts, bonds, &c., shall remain in force, notwithstanding the repeal of the acts and statutes above referred to. The act then proceeds to the subject of the appointment, salaries, and current expenses of the registrars. It then points out in the following terms the law as to societies hereafter instituted.

Friends, Society of || Friesland.

"It shall be lawful for any number of persons to form and establish a friendly society under the provisions of this act, for the purpose of raising by voluntary subscriptions of the members thereof, with or without the aid of donations, a fund for any of the following objects, viz.:—1. For insuring a sum of money to be paid on the birth of a member's child, or on the death of a member, his wife, or child. 2. For the relief or maintenance of the members, their husbands, wives, children, or kindred, in old age, sickness or widowhood, or the endowment of members or nominees of members at any age. 3. For any purpose which shall be authorised by one of her majesty's principal secretaries of state, or in Scotland by the Lord Advocate, as a purpose to which the powers and facilities of this act ought to be extended; provided that a society established under this act shall not assure the payment of an annuity exceeding L.50 per annum, nor a sum payable on the death of any person, or on any other contingency exceeding L.200. The bill further enacts that no money shall be paid by any society upon the death of a child under ten years of age, "except upon the production of a copy of the entry on the register of births and deaths, signed by the registrar of the district in which the child shall have died," and that the cause of death shall be certified by a qualified medical practitioner; and further, that the sum to be paid shall not exceed L.6 in the case of the death of a child under five years of age, nor L.10 in that of a child between five and ten years of age. The remainder of the bill, which contains forty-nine clauses, refers to matters of detail regarding the appointment of officers, the rules of societies, the receipts and payments by societies, their property and the mode of its investment, the determination of disputes, and the returns made to the commissioners. (R. W. F.)

FRIENDS, Society of. See Quakers.

FRIESLAND, or Vriesland, sometimes by foreigners called *West* Friesland, to distinguish it from *East* Friesland in Hanover, is the most northerly province of Holland. It is bounded on the S.W., W., and N., by the Zuyder Zee and the North Sea; on the E. by the provinces of Groningen and Drenthe; and on the S.E. by that of Overyssel. The area is 1280 square miles English; and the population on 31st December 1853 was 259,508, being on an average 203 persons to the square mile.

So similar and identical in surface and soil is Friesland with the province of North Holland, that no geologist doubts they formed one country antecedently to that convulsion in the thirteenth century, which made an inlet for the Zuyder Zee, now separating them. Many parts of Friesland lie below sea-level, and are protected against inundations of the North Sea by artificial dykes raised and kept in repair at a great expense. The entire surface is flat, and intersected by canals; the only elevations being the *tarpeu* (mounds), on which the ancient inhabitants were accustomed to take refuge from the inundations of the sea. Interspersed with the entire surface there are deep swamps, marshes, and bogs, with sandy and moory tracts, or low miserable woodlands. The Great Canal commences at Haarlingen, a port on the west coast, and passes through Franeker, Leeuwarden, and Dokkum, to Groningen. Mostly all the minor and intersecting canals, many of which are above the surface-level of the country and have the water pumped into them, have enabled the inhabitants to cultivate the soil, which otherwise could not have been drained, as well as to transmit the produce to suitable markets. The Great Canal unites with another which runs southward to Sneek, from which, by several small lakes, the communication is completed to Lemmer, on the Zuyder Zee. The expense of maintaining the dykes is raised by a dyke-tax upon the landowners; and the whole management of the canals, dykes, and sluices, is under the administration of the "Water-Staat," who exercise a watchful superintendence over the whole system of water communication in the province. The more elevated grounds are generally appropriated to the cultivation of grain, while the lower soils, especially near the N.W. coast, are set apart for grazing. Though there is no river of any importance in this province, we may mention the Boorn, in the centre, and the Linda and Kuinder, which join just close to their entrance into the Zuyder Zee, and the Lawer, which falls into the Lawer Zee, a small inlet on the N.E. coast. The Lawer only is navigable for small craft; the other two are short, broad rivulets. The small lakes are very numerous, and well stocked with fish of useful kinds. The people of Friesland are principally occupied in dairy husbandry, digging turf for fuel, and fishing. The stock of cattle is so large, that the annual produce for export amounts to 50,000 cwts. of butter and 10,000 cwts. of cheese. With the exception of the *kanter-kaas*, the cheese, as well as the butter, are much inferior to those of the western provinces of Holland. Sheep are numerous, but of very inferior breeds, and the wool is coarse. Horses are bred in large numbers, and are much sought after as carriage-horses, being tall and strong limbed, but unfortunately soft in the hoof. Pigs are reared in immense numbers, especially for the lard they produce. The honey of Friesland has long been in high repute, having its peculiar flavour from the clover so universally cultivated. Manufactures are few, including little more than the common necessaries of life, with wooden clocks, linen, sail-cloth, woollens, iron-wares, paper, salt, spirits, potato-starch, and tiles.

Friesland is divided into three districts; Heerenveen and Sneek in the south, and Leeuwarden in the north. The chief towns of the province are Leeuwarden, the capital; Bolswaart, Franeker, Haarlingen, Dokkum, Stavoren, Sneek, Workum, and Heerenveen.

The islands Terschelling, Ameland, and Schiermonikoog, off the north coast, belong to Friesland. The largest of these is Terschelling, containing about 26,000 inhabitants engaged in agriculture and fishing.

The ancient inhabitants of Friesland were a branch of the Frisii. In the fourth and fifth centuries they allied themselves with the Saxons, whom they assisted in the conquest of Britain. Pepin, major-domo of the Franks, put their king Radpod to flight, and wrested from them their western lands between the mouths of the Schelde and the Rhine. By Charlemagne the Frisians were subdued and put under dukes appointed by him. See Frisii.

Friesland, East. See Aurich.

FRIEZE, in *Architecture*, that part of the entablature of columns which is between the architrave and cornice. See Glossary to Architecture.

Frieze, or Frize, a kind of coarse woollen cloth, so called as being friezed or napped on one side. See Woollen Manufacture.

FRIGA, or Frea, in *Scandinavian mythology*, the wife of Odin.

FRIGATE (Fr. *frégate* (?); Lat. *aphractus*, a long undecked vessel); a ship of war, usually of two decks, designed for swift sailing. Frigates mount from 20 to 44 guns, and sometimes more. The name was originally applied to a long kind of vessel navigated in the Mediterranean with sails and oars.

FRIGATOON, a Venetian vessel with a square stern and without a foremast, having only a main-mast, mizen-mast, and bow-sprit.

FRIGENTO, or Fricento, a town of Naples, province of Principato Ultra, 17 miles E.N.E. of Avellino. Pop. 3000. In the vicinity is the celebrated lake of Ampsanctus. See Ampsancti Vallis.

FRILAZIN, the name of a class of persons among the Anglo-Saxons, which consisted of those who had once been slaves but had obtained their liberty. Though in reality freemen, they were not considered as of the same rank with those who had been born free, and were still dependent on their former masters, or on some new patron. This custom the Anglo-Saxons derived from their ancestors in Germany, among whom the condition of freedmen was esteemed little above that of slaves.

FRISCHE HAFF (*i.e.*, *Fresh-water Sea*), an extensive lagoon, in the northern part of the Prussian provinces of East and West Prussia. It is 48 miles in length from S.W. to N.E., and from 4 to 10 miles in width. It is separated from the Baltic by a narrow tongue of land 43 miles in length, at the eastern extremity of which it communicates with that sea by a channel called the Gatt.

FRISI, Paul, a profound mathematician and astronomer, was born the 13th of April 1728 at Milan. His family had formerly emigrated from Strasburg, and was established at Milan in an humble station of life.

At the age of fifteen he entered into the convent of the Barnabite friars, or of the congregation of St Paul, where his studies were at first confined to the attainment of some knowledge of geography from the contemplation of the old maps that were pasted on the walls of the galleries; he soon acquired, however, a taste for geometry, and made considerable progress in it without an instructor. He was sent to the university of Pavia to go through a course of divinity, and he did not neglect the opportunity of applying with increased diligence to the mathematics, with the assistance of Professor Olivetano. He was afterwards removed to Lodi, in order to give lectures there on philosophy; and he soon after distinguished himself by writing a most able essay on the *Figure of the Earth*, which, however, he had not the means of printing, as his brethren were unwilling to assist him, until he found a patron for his publication in the Count de Silva, who undertook to bear the expense. The credit which he acquired induced some other members of the society to follow his example, and the convent of the Barnabites at Milan soon began to be converted into a nursery of mathematics. His reputation procured him also, from the king of Sardinia, the appointment of professor of philosophy in the college of Casale. Here, however, he thought the conduct of his superiors unjust and tyrannical, and they were also dissatisfied with him on account of his great intimacy with Radicati, whose opinions were rather more liberal than they thought it prudent to tolerate. This friendship was, however, so far of advantage to Frisi, as it tended to improve his taste in modern literature; but it was the principal cause of his being removed to Novara, where he was obliged to undertake the duties of a preacher. In the mean time he was nominated a corresponding member of the Parisian Academy of Sciences in 1753, and received similar honours from other scientific bodies. Soon after this he was recalled to Milan, and made professor of philosophy in the great Barnabite College of St Alexander in that city. His dissertation on the *Figure of the Earth* was very acrimoniously attacked by a young Jesuit, who accused him of being improperly led away by English and French innovations; but it was easy for him to repel so unfounded a charge. From this time he entertained much ill humour against the Jesuits in general, and had written a work to depreciate the order, but he was advised by his second brother to suppress it

He became, however, more and more connected with the enemies of the Jesuits, and, among them, with D'Alembert, Condorcet, and the other Encyclopédistes. He had before this time declared himself, in his lectures, an enemy to the popular opinions of the Italians respecting magic and witchcraft, though he felt himself in some danger of the animadversions of the Inquisition. He was much in the habit of frequenting the best societies in Milan, and even more than was thought consistent with his religious character; but he was in some measure emancipated from the restraints of his order by his appointment, in 1756, to a professorship in the university of Pisa, for which he was indebted to the Grand Duke Leopold. This situation he retained for eight years, enjoying the highest degree of credit, and receiving marked attention from all travellers of distinction, and saving at the same time a considerable portion of his salary, to which he added the amount of some prizes which he obtained from Berlin and Petersburg in 1756, and from Paris in 1758. Notwithstanding his occupations as a professor of moral philosophy, he had always been in the habit of devoting the greater part of his attention to the mathematical sciences. In 1757 he was made an associate of the Imperial Academy of Petersburg, and a foreign member of the Royal Society of London; in 1758, a member of the Academy of Berlin; in 1766, of that of Stockholm; and in 1770, of the Academies of Copenhagen and of Berne. The Archduke Joseph had sent him, in 1759, a collar with a gold medal, and he received similar marks of distinction from the kings of Prussia and Denmark. He was also liberally rewarded by Pope Clement XIII. for his services in arranging a dispute between the people of Ferrara and of Bologna on the subject of rivers and torrents, which had been referred to him on the occasion of a tour that he made to Naples and to Rome in 1760. The senate of Venice also made him a proper acknowledgment for the assistance he gave to the commissioners whom they had appointed to control the ravages of the Brenta. The Empress Maria Theresa settled on him a pension of 100 sequins, or L.50 a-year. He was recalled to Milan in 1764, as professor of mathematics in the Palatine schools, with appointments equal to those which he had enjoyed at Pisa, and with the additional advantage of living near his family, and being enabled to promote their interests. He was at various times much engaged in the decision of controversies respecting canals and rivers, and obtained much credit for his skill and ingenuity; though the peculiarities of his temper tended somewhat to increase the number of his enemies. Among other controversies, he was engaged in a dispute respecting the propriety of adding a high pinnacle to the dome of the church at Milan, which has since been raised in opposition to his opinion. In 1766 he undertook a journey into France and England, and his celebrity everywhere procured him the most flattering attentions. At Paris a very liberal proposal was made to him to remove to Lisbon, but he preferred returning to his own country. In 1768 he went to Vienna, and he was consulted by the government there upon some important questions of ecclesiastical policy, in which his advice was adopted. He remained but little longer in the college of St Alexander, and Pope Pius VI. liberated him entirely from subjection to the superiors of his order, and allowed him to wear the habit of a secular priest. As one of the censors of the press, he had incautiously been accessory to the publication of the *Lanterna Curiosa*, the work of a coffee-house club in Milan, which gave great offence to the government; and he afterwards still more imprudently undertook to defend it. This circumstance occasioned his removal from Milan for a time, but he was recalled in 1777, and was appointed director of a school of architecture. He was active in introducing the employment of conductors for security against lightning, and had one fixed for an example on the repository of the public archives. He was equally zealous on every other occasion in the dissemination of useful novelties among his countrymen. In 1778 he made a tour into Switzerland, and his observations there gave rise to his speculations on subterraneous rivers. He enjoyed uninterrupted health until the age of forty-eight, when he was attacked by a hæmorrhoidal affection, ending in an abscess, which, eight years afterwards, required the performance of an operation. This was unfortunately succeeded by a fatal mortification, and he died the 22d November 1784, at the moment when he was about to be placed on the list of the eight foreign associates of the Parisian Academy; an honour which had been delayed by the preference of J. A. Euler, on the occasion of a former vacancy, to the no small mortification of his vanity. He had very lately obtained a prize from the Academy of Haerlem, for his memoir on the *Inequality of the Satellites of Jupiter*. He was buried in the church of St Alexander, and a medallion with his portrait was placed over his tomb by his brethren Barnabites. He had four brothers, Antony, a physician, botanist, and chemist; Antony Francis, an ecclesiastic, author of some antiquarian researches of merit; Louis, a canon of St Ambrose, a learned theologian and mechanician; and Philip, a lawyer, author of a dissertation *De Imperio et Jurisdictione.*

The works of Father Paul Frisi are—1. Disquisitio mathematica in causam figuræ terræ, Milan, 1751; demonstrating, more completely than Newton had done, the spheroidal figure of the earth. 2. Estratto della storia litteraria d'Italia, Milan, 1753; an answer to a review. 3. Saggio della morale filosofia, Lugano, 1755. 4. Nova electricitatis theoria, Milan, 1755. Seems to be the same with a dissertation De existentia et motu ætheris, seu de theoria electricitatis, ignis, et lucis, printed with J. A. Euler's Disquisitio de causa physica electricitatis, præmio coronata, 1755, 4to, Petersburg. This dissertation shows some ingenuity, but is by no means established on firm foundations. Among some other fanciful hypotheses, it suggests that light is probably an impulse transmitted by an elastic medium, but not of an undulatory nature. Both these essays seem to have been republished at Lucca, with another by Resaud, under the title of Dissertationes selectæ quæ ad I. P. academiam, anno 1755, missæ sunt, 1757. 5. De motu diurno terræ, Pisa, 1758; a dissertation which obtained a prize from the Academy of Berlin in 1756. 6. Dissertationes variæ, 2 vols. 4to, Lucca, 1759, 1761; the first volume containing a geometrical solution of the problem of Precession and Nutation; a Dissertation on the Atmospheres of the Heavenly Bodies, which obtained the prize at Paris in 1758; an Essay on the Nature and Motion of the Ether: the second, a Treatise on the Inequality of the Motion of the Planets, being an enlargement of a prize dissertation which obtained the second premium at Paris in 1760; a Dissertation on the geometrical method of Fluxions, and some Metaphysical Meditations. 8. Piano de lavori per liberare dalle acque, Lucca, 1761; for the use of the provinces of Bologna, Ferrara, and Ravenna. 9. Del modo di regolare i fiumi e torrenti, Lucca, 1762, 1760; Flor. 1770; French, Paris, 1774; especially of the Bolognan and Roman territories, making great use of Guglielmini's works. At the end there is an Elogio di Gabriello Manfredi. 10. Prælectio habita Mediolani; 1764. 11. Saggio sopra l'architextura Gotica, Leghorn, 1766. 12. Lettre à M. d'Alembert, Par., 1767. 13. Elogio del Galileo, Leghorn and Milan, 1775; French by Floncel, 12mo, Par., 1767; an elegant specimen of biography. 14. On the supposed Inequalities in the Rotation of the Earth and Moon, Inst. Bologn., vol. 5. Op., p. 11 (1787). The same volume contains a prospectus of the work on the Laws of Gravity, p. 514. 15. De gravitate universale libri tres, 4to, Milan, 1768; a work considered as a model of elegance, simplicity, and facility; leaving, however, the fact of the moon's acceleration still unexplained, and even stating doubts of its existence. 16. Della maniera di preservare gli edifizi dal fulmine, Milan, 1768; by conductors. 17. De inequalitate motus planetarum, a dissertation which obtained the second premium at Paris in 1768. 18. Melandri et Frisii de theoria lunæ commentarii, Parma, 1769. 19. Cosmographia physica et mathematica, 2 vols. 4to, Milan, 1774, 1775; this is Frisi's principal work; it contains the substance of the three books on the laws of gravity, with additional matter. It is only superseded by the *Mecanique Céleste* in point of practical utility, but still retains the advantage of more satisfactory geometrical representation, and less unnecessary complication in the modes of reasoning employed. 20. Dell architextura, statica e idraulica, Milan, 1777. 21. A Letter to Melander on the transit of Venus, *Attidi Sienna*, vol. iv., p. 21 (1771); with some illustrations of the lunar perturbations. 22. Geometrical problems, ib.

vol. v., p. 27 (1772); relating to intersections and circles. 23. Elogi di Galileo e di Cavalieri; Milan, 1778; Pisa, 1779. 24. Elogio del Cav. I. Newton, 8vo, Milan, 1778. 25. Elogio del Conte D. Silva, Milan, 1779; anonymous. 26. Elogio di Tito Pomponio Attico, Milan, 1780; a compliment to the Count de Firmian. 27. Opuscoli filosofici, Milan, 1781; denying the fancied influence of the moon on the weather, which Toaldo very unsuccessfully attempted to assert in answer; with dissertations on Conductors, on the effect of Oil on Water, on the Heat of the Earth, and on Subterraneous Rivers. 28. On isoperimetrical maxima and minima, *Atti di Sienna*, vol. vi., p. 121 (1781); intended as a simpler mode of obtaining the results than that of Euler. 29. A Collection of his Works, in 3 volumes, was begun in 1782, and remained unfinished at the time of his death. The first volume contained Algebra and Geometry; the second, Mechanics and Hydraulics; the third, the Cosmography. 30. Elogio di Maria Teresa, Pisa, 1783; anonymous. 31. Lettera intorno agli studj del Sign. T. Perelli, Pisa, 1784. 32. Elogio di D'Alembert, Milan, 1788; posthumous. 33. An Essay on Arches and Domes, *Atti della Società Patriotica di Milano*, vol. i., 1783; correcting some statements of Couplet and Belidor.

He left several unpublished works in the hands of his two brothers: 1. On the mediocrity of the Jesuits. 2. Elements of the Cartesian Algebra. 3. Institutions of Mechanics. 4. Of the restoration of the navigation between Milan and Pavia. 5. Institutiones Hydrometricæ. 6. Elements of Hydrodynamics. 7. Elements of Hydraulics. 8. Memoirs of his travels in France and England. 9. Lectures delivered at Pisa. 10. Prælectiones de malis spiritibus. 11. Several miscellaneous dissertations.

(Verri *Memorie del S. D. P. Frisi*, 4, Milan, 1787; Fabbroni *Elogj d'illustri Italiani*, *Atti di Milano*, vol. ii.; Chalmer's *Biographical Dictionary*, vol. xiv. 8, London, 1814; Aikin's *General Biography*, vol. x. 4, London, 1815; Guillon in *Biographie Universelle*, vol. xvii. 8, Paris, 1816.) (T. Y.)

FRISII, in *Ancient Geography*, a German tribe forming part of the nation of the Ingævones. Their country extended along the sea-coast from the mouth of the Rhine to that of the Amisia or Ems, and extended inland as far as the territory of the Bructeri. They were divided into the Frisii Majores who occupied the district that corresponds with the modern provinces of West Friesland and Groningen, and Frisii Minores, whose territory is represented by the present provinces of Oberyssel, Guelders, Utrecht, and the greater portion of the province of Holland. The Frisii were separated from the Batavi by the Rhine, and by the Amisis from the Chauci. The Frisii were at first firm friends and allies of the Romans, and such they continued till A.D. 28, when, enraged by the tyrannical conduct of the Roman lieutenant Olennius, they rose in arms against them, and compelled them to evacuate the country with great loss. Corbulo, the general of Claudius, reduced them to a kind of sullen obedience in A.D. 47; and Nero compelled them to abandon some conquests they had made on the southern side of the Zuyder Zee. In the fourth and fifth centuries they appear as members of the great Saxon Confederacy, and assisted the Angles and Saxons in their conquest of Britain. In the eighth century, Epin, the father of Charlemagne, wrested from the Frisii the western portion of their territory, and Charlemagne incorporated the Eastern part among his other Saxon conquests.

FRIT, or Fritt, the name given to the ingredients of which glass is made, after they have been fused into a mass, or calcined, in a furnace. See Glass.

FROBENIUS, Joannes, an eminent German printer and scholar of the sixteenth century, was born at Hammelburg in Franconia. After completing his university career with great distinction at Basle, he established a printing office in that city about the year 1491, and was the first German who brought the art to anything like perfection. He superintended everything himself, and would allow nothing to pass through his press which he thought likely to prejudice the cause of letters or religion. Attracted by the high character of Frobenius as a man and as a printer, Erasmus fixed his residence at Basle, and was soon on terms of intimate and cordial friendship with him. A result of this connection was that Erasmus not only had his own works printed by his friend, but superintended editions of St Jerome, St Cyprian, Tertullian, Hilary of Poictiers, and St Ambrose. It was part of Frobenius' plan to have printed also editions of the Greek Fathers. He did not live to carry out this project, which however was very creditably executed by his son Jerome and his son-in-law Bischof or Episcopius. Frobenius died in 1527, in consequence of an accident which had befallen him some years before. An extant letter of Erasmus, written in the year of Frobenius' death, gives an epitome of his life and an estimate of his character, which was so amiable that Erasmus says he began at length to feel ashamed of his grief for the death of his friend, which was far more poignant than that which he had felt for the loss of his own brother. The epistle concludes with an epitaph on Frobenius in Greek and Latin, written by the great scholar himself.

FROBISHER, Sir Martin, a celebrated English navigator of the sixteenth century, was born (in what year is not known) at Doncaster in Yorkshire. He was the first Englishman that sailed in quest of the north-west passage to China and the Indies. "Being thoroughly furnished of the knowledge of the sphere and all other skills pertaining to the art of navigation, and being persuaded of a new and nearer passage to Cataya than by Capo de Buona Sperança, which the Portugals yearly use, and knowing this to be the only thing of the world that was yet left undone, whereby a notable mind might be made famous and fortunate," he applied to various English merchants to assist him in his projected enterprise, but for fifteen years without success. At the end of that period he was enabled, through the assistance of Dudley, Earl of Warwick, and others, persons of rank and fortune, to set out on the expedition. He sailed from Deptford, June 15th, 1576, with three small vessels, two of them, the Gabriel and the Michael, barks of twenty-five tons each, and the third a small pinnace of ten tons. As they passed Greenwich, the queen, who happened to be there with her court, "commended them, and bade them farewell with shaking her hand at them out of the window." After passing the Shetland islands they came in sight of "Freeseland" (July 11th), where they were unable to land on account of the ice, and on the 28th of the same month they reached that part of Greenland which Frobisher named "Meta Incognita." On the 11th August they sailed through a strait which Frobisher called by his own name. Pursuing their way they passed several islands, to which they gave names, and came on the 18th to Burcher's Island, where they lost a boat and part of their crew through the treachery of the natives. After this they turned their prows homewards, and reached England, September 7th. Frobisher had taken possession of the various places he touched at in the name of the queen; and in token of this had ordered his men to put on board ship whatever they first laid hands on. Among other things thus secured was a lump of black stone, which, when Frobisher returned home, was accidentally discovered to contain gold. This discovery was soon noised abroad, and in the following spring Frobisher readily found the means to fit out another expedition, partly scientific and partly with a view to prosecuting the search for gold. The queen lent him from the royal navy a ship of 200 tons, with which, and two smaller barks, he sailed from Harwich, May 31, 1577. On arriving at the scene of their former discoveries they found that little of the gold ore remained, but they opened forthwith communications with the natives for the purposes of traffic. One of these, "a man of large corporature and good proportion," they carried away with them neither in a very just nor handsome manner. They also caught an old woman, "whom they took for a devil or a witch," and stripped off her buskins "to see if she were cloven-footed." After discovering and naming a good many places, and procuring a good deal of ore, he turned his prow southwards, August 23d, and reached home in the end of September. The ore, when smelted, was found to pay the expenses of the voyage and more; and a third expedition was fitted out in 1578, which, however, through stress of weather and other circumstances, had no sooner reached the gold country than it was obliged to return from the lateness of the season. This was the last of Frobisher's polar voyages. It is not known how he was occupied during the next seven years, but in 1585 he accompanied Sir Francis Drake on his expedition to the West Indies, and three years later did such good service against the Spanish armada as to be rewarded with the honour of knighthood on board his own ship by the lord high admiral. In 1594, after various exploits against the Spaniards, he was sent to assist Henri IV. of France against the Spaniards and the members of the League. The enemy had fortified themselves strongly in Croyzon, near Brest; and in an attack on their position Frobisher was mortally wounded. He lived to take his fleet safely home, and shortly after died at Plymouth.—(*Biog. Brit.;* Hakluyt's *Collect. of Voyages;* Stow's *Annales*, &c. &c.)

FROBISHER STRAIT, an arm of the sea, in British North America, between Hudson Strait and Northumberland Inlet. It extends in a westerly direction from the entrance to Davis' Strait.

FRODSHAM, a market-town of Cheshire, near the Weaver and Mersey rivers, 10 miles N.E. of Chester. It has a fine old church, partly Norman, and a free grammar-school, savings-bank, graving dock, and flour mills. Pop. (1851) 2099, chiefly employed in the salt-works and cotton manufacture.

FROISSART, JEAN, the author of the celebrated "Chronicle," was born at Valenciennes about the year 1337. He was the son of Thomas Froissart, a heraldic painter, an honourable employment in those the palmy days of chivalry. At an early age he distinguished himself by his proficiency in all the elegant accomplishments of his day. He had hardly left school when he devoted himself to the study of history, and, at the request "de son cher seigneur et maître, Messire Robert de Namur, chevalier Seigneur de Beaufort," undertook to narrate the wars of his own time, especially those which followed the battle of Poictiers. To dissipate his grief for the marriage of a young person for whom he had conceived a violent passion, he went to England, where he was kindly received by Philippa of Hainault, wife of Edward III. and mother of the Black Prince, who made him her private secretary. In her employment he remained for three or four years, and took advantage of his opportunities to visit Scotland, where he spent six months, travelling on horseback through the country, his only attendant being his greyhound. He was well received by David II. of Scotland and some of the leading nobility, whose exploits he afterwards recorded. After a flying visit to Bordeaux in 1366, he returned once more to England, where however his stay appears to have been brief, as two years later we find him visiting various Italian courts. He particularly describes his visit to that of Savoy, where he was present at the splendid fêtes given by Amadeus, surnamed the Comte Verd, in honour of Lionel duke of Clarence, and does not forget to mention that the guests danced a virelay of his composition. At Milan the same Count Amadeus presented him with a splendid *cotte-pardie* and twenty gold florins. On parting from this munificent patron, Froissart repaired successively to Bologna, Ferrara, and Rome. Instead of the meagre equipage with which he had travelled through Scotland, he had now a handsome steed for himself and a sumpter-horse for his servant and baggage. About this time he lost his protectress, Philippa of England, whose death he deeply deplored, and whose virtues he commemorated in a dirge; and it is even said that he wrote a life of her, but if he did he never published it. On returning to his own country he obtained the living of Lestines, where he indulged himself more than was at all becoming in a churchman. During the short time that he held that cure he says that the tavern-keepers received five hundred francs of his money. After this Froissart attached himself successively to Wenceslaus of Luxembourg, duke of Brabant, for whom he made a collection of his songs and virelays, and to Guy, count of Blois, who made him clerk of his chapel. At the instance of this latter patron Froissart resumed the composition of his history, which had been interrupted, and to amass materials he paid a visit to the court of the famous Gaston de Foix. That prince had fixed his residence at that time at Ortez, and his court was thronged with the noblest chevaliers of Europe. Froissart's description of his sojourn there is one of the most interesting parts of his "Chronicle." On quitting Ortez the historian went to Flanders in quest of materials for his work, and after various pilgrimages made with the same object he at length settled down at Paris to complete it at his leisure. In 1395 he revisited England, where he was hospitably received by Richard II., and presented with a silver goblet containing a hundred nobles; and on returning to France he became canon and treasurer of the church of Chimay. These offices he held till his death, which appears to have happened about the beginning of the fifteenth century. Froissart's poetry, very celebrated in its day, and now almost forgotten, embraces nearly 30,000 verses. His "Chronicle," on the other hand, less appreciated during the author's lifetime, is now regarded as one of the most interesting historical monuments of the middle ages. It contains the history of the fourteenth century from 1326 to 1400. The first edition of it appeared at Paris under the title of *La Chronique de France, d'Angleterre, d'Ecosse, d'Espagne, de Bretagne*, &c., without a date, and was often reprinted. The best of the early editions was that published at Lyons, 1559-61, in 4 vols. fol., by Denis Sauvage. Of recent editions the best is that by J. A. Buchon, in 15 vols. 8vo, forming part of the *Collection des Chroniques Nationales Françaises*, Paris, 1823-26. There are two English translations of Froissart; the first by Bourchier lord Berners, London, 1525-26, reprinted in 1812 by E. V. Utterson, Esq., in 2 vols. 4to.; the second, "which contains additions from many celebrated MSS.," by Thomas Johnes, Esq., issued from the Hafod press, in 4 vols. 4to, 1803-5. (For a more particular account of Froissart's "Chronicle," see CHIVALRY.)

FROME, a parliamentary borough and market-town of Somersetshire, on the small river Frome, an affluent of the Avon, 11 miles S. of Bath. It was formerly designated *Frome Selwood*, from its situation on the borders of the extensive forest of Selwood. The Frome is here crossed by a stone bridge of five arches, and the town is irregularly built upon an acclivity rising from the river. With the exception of the principal street, most of the others are narrow and irregular, although within the last few years considerable improvements have been carried out. The parish church is an elegant edifice in the later Gothic style, with a tower and a fine octagonal spire 120 feet in height. There are two other churches and several dissenting places of worship. Among the educational and charitable institutions are a free grammar-school, a national school, an asylum for the education and maintenance of 25 poor girls, a blue-coat school, a charity school, and almshouses for old men and women. The inhabitants are chiefly employed in the broadcloth and silk trades. This town has been long noted for its ale. The principal market is held on Wednesday, a lesser one on Saturday. The vicinity is fertile and picturesque, and ornamented with numerous fine mansions. Frome, since the passing of the Reform act, returns one member to parliament. Pop. (1851) 10,148.

FROMISTA, a secular town of Spain, in the province and bishopric of Palencia, with 1529 inhabitants. It contains three churches, one convent, and two hospitals, and is situated in a beautiful plain near the river Cieza and the Canal de Campos. There are in and around it numerous relics and indications of its ancient grandeur. The land around it is very rich and fertile, but utterly destitute of trees, on account of the incurable dislike to them manifested by the inhabitants. Fromista was the birthplace of San Telmo and other men of note.

FRONTAL, in *Architecture*, a little pediment over a small door or window.

FRONTINUS, Sextus Julius, a Roman soldier and the author of some interesting works, was born of a patrician family at Rome, in the first century after Christ. Nothing is known of his early life or history till we find him acting as *prætor urbanus* under Vespasian, A.D. 70, an office from which he soon retired to make way for Domitian. Five years later he was sent into Britain to succeed Cerealis as governor of that island. He subdued the Silures, and held the other native tribes in check till 78, when he was superseded by Agricola. In 97 Frontinus was appointed *curator aquarum* at Rome, an office which was never conferred except upon persons of very high standing. He was also a member of the College of Augurs, a dignity he retained till his death, which appears to have happened about A.D. 106. Many works have been attributed to Frontinus, of which only two that are undoubtedly his are now extant. The first of these is a treatise on the art entitled "Strategematicon, libri iv.," which is a miscellaneous collection of the sayings and doings of the most famous soldiers of antiquity, recorded in the form of anecdote. The second is entitled "De Aquæductibus Urbis Romæ, libri ii." It conveys in plain and modest language much valuable information on the manner in which ancient Rome was supplied with water, and other matter of importance in the history of architecture. A number of other treatises have been ascribed on indirect testimony to Frontinus. The two works above mentioned have been translated into all the languages of Europe. The best editions of the "Strategematica" are those of Oudendorp, Leyden, 1731; and Schwebel, Leipzic, 1772. The best edition of the "De Aquæductibus" is that of Polenus, Pavia, 1722.

FRONTISPIECE (*frons* and *specio*), in *Architecture*, the principal face of a building. Hence also an ornamental figure or engraving in the beginning of a book.

FRONTO, Marcus Cornelius, a Roman grammarian and rhetorician, was born of an Italian family at Cirta in Numidia. He came to Rome in the reign of Hadrian, and soon gained such renown as an advocate and orator as to be reckoned inferior only to Cicero. Antoninus Pius, hearing of his fame, appointed him tutor to his adopted sons Marcus Aurelius and Lucius Verus; and Fronto, as appears from his surviving letters, completely gained the confidence and affection of both these pupils. After holding the office for a few months in A.D. 143, he was five years later offered the proconsulate of Asia; but declined that post on the plea of bad health. He preferred to remain at Rome, where by the practice of his profession he amassed a very large fortune, which enabled him to purchase the famous gardens of Mæcenas, besides sumptuous villas in various parts of Italy. In his old age, when confined to his house by the gout, he used to receive the leading literary men, who flocked to hear his unrivalled conversation. This exhibited the same qualities as his more formal orations, which were so much admired that a school of rhetoricians was formed which called itself after his name, and had for its object the restoration to the Latin language of its ancient purity and simplicity. Fronto died at an advanced age, in the reign of Marcus Aurelius, but the exact date of his death is not known.

Till the year 1815 the only thing of Fronto's known to exist was some disjointed fragments of his essay *De Differentia Verborum.* In that year, however, Angelo Mai discovered in the Ambrosian library at Milan a palimpsest manuscript, on which had been originally written some of Fronto's letters to his royal pupils. These Mai decyphered and published with notes. On Mai's removal to Rome he discovered in the Vatican some additional sheets of the same palimpsest, which, like the first, contained letters of Fronto to Aurelius and Verus, with their replies. These palimpsests had originally belonged to the famous convent of St Columba at Bobbio, and had been written over by the monks with the acts of the first council of Chalcedon. In the course of events some sheets of them had been transferred to Milan, while the rest had found their way into the Papal library. All these letters were published by Mai at Rome in 1823, under the title of *M. Cornelii Frontonis et M. Aurelii imperatoris epistolæ; L. Veri et Antonini Pii et Appiani epistolarum reliquiæ; Fragmenta Frontonis et scripta grammatica.* The discovery of these documents excited intense interest among the scholars of Europe, which, however, was speedily dispelled by their publication. The characters of the two emperors, indeed, are displayed in a very favourable light, especially in the affection which they both seem to have retained for their old master. But the subject-matter of most of the letters is of such ephemeral interest, and their style is so vapid and commonplace, as to throw very little additional light on Roman antiquity. Editions of Fronto have been published at Frankfort and Berlin. A French translation of Mai's edition of 1823 was published by Armand Cassan at Paris, in two vols. 8vo, in 1830.

FROSINONE, the ancient *Frusino*, a town of the Papal States, capital of a cognominal delegation, at the foot of a hill near the left bank of the Cosa, 46 miles E.S.E. of Rome. The ancient city stood on the *Via Latina.* It originally belonged to the Volsci, and was subsequently colonized by Roman veterans. Some remains of an amphitheatre are still visible in the plain beneath, but the town itself contains no relics of antiquity. The town is very ill built, but has numerous churches and convents. It is the seat of a bishopric, and of a court of primary jurisdiction. A large annual fair is held here. Being situated near the Neapolitan territory, its neighbourhood is notorious for brigandage. Pop. about 7000.

The delegation of Frosinone is bounded on the N. and N.W. by the Comarca di Roma, S. and S.W. by the Mediterranean, and on the E. and S.E. by the Neapolitan province of Terra di Lavoro. It has an area of 720 square miles, and a population (1850) of 148,378.

FROST. See Climate, Cold, and Meteorology.

Hoar-Frost is atmospheric vapour that has been deposited in the form of dew, and frozen.

FROTH SPIT, or Cuckoo Spit, a name given to a white spume or exudation found on the leaves of certain plants; produced by the larva of the insect *Cicada spumaria.*

FROWDE, Philip, an English littérateur of the eighteenth century. He was educated at Oxford, where he formed the acquaintance and enjoyed the intimate friendship of Addison. Some of his Latin poems were considered worthy of a place in the *Musæ Anglicanæ.* His tragedies of *Philotas* and the *Fall of Saguntum*, dedicated respectively to Lord Chesterfield and Sir Robert Walpole, do not exhibit any high literary merit, and are remembered more from their refinement of tone and the extremely amiable character of their author than from any intrinsic value. Frowde died in 1738.

FROZEN OCEAN. See Polar Seas.

FRUIT-TREES. See Horticulture, and Botany.

FRUMENTACEOUS (*frumentum*, corn), resembling wheat, in respect to leaves, ears, fruit, or the like.

FRUMENTARII, under the Roman empire, were officers who acted as spies in the provinces, and reported to the emperor whatever seemed worthy of note. They appear to have derived this appellation from their gathering news in the same way that the frumentarii or purveyors collected corn.

FRUMENTATIO, in *Roman Antiquity*, a largess of corn bestowed on the people, to quiet them when uneasy or turbulent. The number to whom this largess was to be given was restricted by Augustus to 200,000.

FRUSH, or FROG, in *Farriery*, a sort of tender horn that grows in the middle of the hoof of the horse, dividing into two branches, and extending towards the heel in the form of a fork.

FRUSTUM, in *Geometry*, the part of a solid figure that remains when the top is cut off by a plane; or it is that part of any solid, as a cone, pyramid, sphere, &c., which is comprised between two planes, whether they be parallel or divergent. See GEOMETRY, and CONIC SECTIONS.

FRUTEX (Lat. *a shrub*), denotes a plant whose branches are perennial, and proceed directly from the surface of the earth.

FUCA, JUAN DE, a strait on the west coast of North America, Oregon territory, south of Vancouver island, and leading from the Pacific into the Gulf of Georgia. It forms part of the boundary line between the United States and the British territory.

FUCHSIA, a genus of beautiful flowering shrubs, natives chiefly of the temperate parts of America. A great many different species and varieties are cultivated in this country. Class and order Octandria monogynia, and nat. order Onagraceæ. See BOTANY, v., p. 192.

FŬCI, a family of cryptogamous marine plants, generally known as *sea-weed*. See BOTANY, nat. ord. *Algæ*, p. 217, &c.

FUCINUS LACUS (LAGO FUCINO, or LAGO DI CELANO), in *Ancient Geography*, a lake in the country of the Marsi. Strabo describes it as being like a sea in size; and it was undoubtedly the largest body of fresh water in Central Italy; but its circumference does not exceed thirty miles. It is surrounded on all sides by mountains (one of which, Monte Velino, attains a height of more than 8000 feet), and does not appear to have any natural outlet. Its elevation above the sea-level is 2176 feet. Its eastern and western boundaries are limestone ridges of considerable height; on its north-western side it is separated by a gentle slope from the channel of the Salto, a tributary of the Tiber. Several curious traditions are current regarding the Lake Fucinus. One of these is to the effect that it was traversed by a river called the Pitonius, whose waters did not mix with those of the lake. This story appears to have had its origin in the fact that the surplus waters of the lake were carried off by a subterranean channel, the opening of which, still visible, is now called "La Pedogna," a manifest derivative from Pitonius. As the channel, however, was not wide enough to carry off all the surplus water, especially after the heavy rains, the low grounds round the shores of the lake were frequently flooded. One of these floods is said to have engulfed the town of Archippe, and the neighbouring inhabitants had a tradition that when the waters were low the remains of that town might be traced beneath the waves. To prevent the devastation and loss of life consequent upon these inundations, Julius Cæsar formed the great design of cutting a subterranean canal from the lake to the valley of the Liris or Garigliano. Death frustrated this design, which none of his successors had leisure or inclination to carry out before Claudius. That emperor cut a gallery of 15,600 English feet through Mount Salviano; a work of great labour, from the hardness of the limestone rock, and which is said to have occupied 30,000 workmen for eleven consecutive years. This gallery, which is reckoned by Pliny one of the most memorable proofs of Roman greatness, was allowed to fall into decay, and it was gradually choked up with stones and rubbish falling from above. All the efforts that have been made to clear it since the middle of the thirteenth century have not hitherto been wholly successful. Much of the best land in the Abruzzo has consequently been swallowed up. In 1830, however, the king of the Two Sicilies caused some important repairs to be executed on it, which have had the effect of obviating the risk of future inundations. A company was formed at Naples in 1852 to drain the entire lake, which according to a recent official survey covers 36,315 acres. This company does not yet appear to have commenced operations.

FUCUS (φῦκος), a general term among the ancient Greeks and Romans for dyes and paints, more particularly those employed as cosmetics. The custom of painting the face was derived from the oriental nations, among whom it had existed from the earliest times. In order to give a rosy hue to the complexion, the dye commonly used was that obtained from the root of *Anchusa tinctoria* (alkanet plant). To whiten the neck and arms they employed *cerussa* (white-lead), which must soon have injured the fine texture of the skin. The eyebrows and the edges of the eyelids were darkened with a powder called *stimmi* or *stibium* (sesqui-sulphuret of antimony), a substance that is used at the present day by the Turkish ladies for the same purpose; and, according to St Jerome, was the cosmetic used by *the painted Jezebel* of the Scriptures. Soot likewise appears to have been sometimes so employed. The more effeminate of the men, both among the Greeks and the Romans, sometimes used such cosmetics. Various other substances were employed for improving the complexion, more especially among the Roman ladies, who were adepts in this art, even heightening the blue colour of the veins, especially on the temples. The still more objectionable custom of wearing patches (*splenia*), once so prevalent in England, was not unknown to the Romans. (See SMITH'S *Dict. of Greek and Roman Antiquities*.)

FUEL (from the French *feu*, fire, akin to the Latin *focus*, a hearth or fireplace), a word applied to certain substances which are used in the generation of heat, such as wood, peat, coal, &c., and also sometimes applied to the substances employed in generating light, such as oil, spirits of wine, naphtha, &c. In the present article the former application will alone be considered; for information respecting the latter, see GAS-LIGHTING, LAMP, &c.

The abundance and consequent cheapness of fuel has a great influence on the prosperity, habits, and manners of a nation. Where fuel is scarce, factories languish, and commerce declines. In cold climates scarcity of fuel is individually a great calamity, for it abridges the hours of labour, causing persons to spend those hours in sleep which under other circumstances would have been turned to profitable account; it also causes persons to crowd together for the sake of warmth in a way that is injurious to health and morals. Abundance of fuel, on the contrary, with good roads and a system of inland navigation for its distribution, forms the basis of national prosperity, not only ministering to the useful arts, but enabling the occupier of every house to create an artificial climate suited to his wants and wishes.

The most common and widely distributed description of fuel is *wood*, a term applied to the trunk, roots, and larger branches of trees. Recently felled wood consists chiefly of woody fibre, sap, and water. The woody fibre is a compound of carbon, hydrogen, and oxygen, and forms the chief bulk of plants; both it and the sap are combustible—that is, are capable at a high temperature of combining rapidly with the oxygen of the atmosphere and forming gaseous compounds. It is in the act of this formation that heat is generated. The sap, which forms only a small proportion of the bulk of wood, varies in different kinds of trees: the sap of the pine tribe contains resin; that of the oak, tannin; that of the beech and birch, extractive. The quantity of water in wood varies greatly with the kind of tree, and with the time of year when it is felled, it being least in winter. As the water is not combustible but must be got rid of at the expense of the heat generated by the parts which are so, it is obviously desirable to store the wood in a dry and airy situation before using it as fuel. By this means 100 lb. weight of wood have been known to lose 20 lb. weight in ten or twelve months. Wood, as commonly used for fuel, contains about one-third of its weight of water. Wood also contains earthy and alkaline salts in the proportion of $\frac{1}{30}$th to $\frac{1}{70}$th, and these remain as an incombustible ash.

Wood is distinguished from all other fuel by the valuable property of reproduction, and also by the fact that it often passes through various stages of beauty and utility to man before it becomes converted into fuel.

The heating power of wood is considerable, in consequence of its excess of hydrogen, which, in burning and forming water, requires for equal weights three times as much oxygen as the carbon does in forming carbonic acid; and it gives out in burning nearly four times more heat than the carbon. The lighter woods contain more hydrogen than the heavier, so that they burn with flame longer than they incandesce as charcoal; they also burn more easily and give out their heat more quickly than the hard woods.

During the combustion of wood its volatile parts undergo some complicated chemical changes. When wood is burnt out of contact with the air, the carbon is preserved in the form of charcoal (see CHARCOAL), which is a very useful fuel when an incandescent heat free from flame and smoke is required; but when some of the volatile products are to be collected, the wood is placed in iron retorts which are gradually raised to a red heat; the volatile products form carburetted hydrogen, carbonic acid, carbonic oxide, and other gases, and also certain vapours which condense into liquid or solid products; some of the liquids are soluble in water, such as pyroxylic spirit, pyroligneous acid, &c.; the insoluble products form tar and certain oily substances.

In most countries deposits of *peat* occur of greater or less extent. In Holland, the north of Germany, Ireland, &c., peat deposits are of immense extent. The origin of peat has been accounted for in those districts where clay occurs near the surface by supposing muddy pools to have formed, round the edges of which aquatic plants have taken root and gradually extended themselves into the centre, thus forming a bed where mosses accumulate, and new plants take growth, while the old are decaying and becoming compressed into a solid mass below. This process goes on until the pools are filled up with vegetable matter, and the surplus water is discharged over the neighbouring lands, where the process is repeated until a peat bog is formed. Even in mountain districts, where the soil is impervious, clouds and mists may supply moisture, and a bog be formed by the growth of one generation of vegetable matter on the ruins of its predecessor. As the plants which form the peat are in different stages of decomposition at various depths, the character of the peat varies greatly. Near the surface it is light-coloured, spongy, and the vegetable character but little changed; lower down it is brown and dense; while at the base of some bogs, which may be as much as forty feet in depth, the peat is black, almost as dense as coal, and resembling coal in chemical composition.

On the banks of the Rhine peat is cut by means of a spade into blocks, and exposed to the air to dry, the upper layer being first separated from the lower and denser portion. In Holland the peat is scooped out by means of spades; or if a considerable quantity of water be present, an instrument is used consisting of a sharp iron ring attached to a handle, a net or cloth being fastened to the ring for draining off the water. The muddy peat thus collected is trodden out by the feet of men, raked, and the stones picked out; it is then thrown into shallow wooden boxes, strewed with hay to prevent the peat from adhering, and the remaining water is allowed to drain off. In the course of a few days when the mass has attained a certain consistence, women with flat boards strapped to their feet stamp down the peat until it has attained such a consistency as not to take an impression from a common tread. It is next stamped with beaters; and the cake, which is eight or nine inches thick, is divided by means of long laths into squares of about four inches, which are removed a few at a time from each box. The cakes are then dried by placing the first taken out transversely on the second, the third upon the fourth, reversing the order when the pieces are piled up in store.

The value of peat depends greatly upon its dryness, density, and firmness; if porous and brittle it crumbles during carriage or after it is stacked and thus becomes nearly worthless. In many cases the value of peat depends on its capability of being alternated with the substances to be heated. Porous and almost valueless peat has been rendered valuable by being passed through a press, in which case a lump of peat may lose as much as one-fourth of its weight of water. Peat may be nearly valueless as a fuel from the quantity of ash which it affords, consisting of vegetable salts and the earthy matter of peat, and amounting in some cases to one-third of the weight of the peat. When this large quantity of ash occurs in peat it renders the fuel very dusty, and in smelting processes it is objectionable on account of its chemical action. It is remarkable that the carbonates of the alkalies are not found in this ash, but phosphates, sulphates, &c.

In some large towns, peat, or *turf* as it is also called, is imitated by employing the refuse bark of the tan-yard, which is made into flat cakes, and chiefly used as fuel by the poor.

In the sandy plains of the East, camels' dung is dried and used as fuel;[1] it was from the use of such fuel in Egypt that sal ammoniac originated, the salt subliming during combustion. Other descriptions of excrement are also used as fuel. The Chinese have long been accustomed to mix cow dung and other refuse vegetable matter with soft clay and the dust of coal to form balls which when dried in the sun become a cheap and useful fuel, burning with very little smoke. These balls are largely manufactured in the coal districts of China, and are distributed over the empire by means of the canals. It is a curious fact that Sir Hugh Platt,[2] in 1594, indicated a method of making coal balls with loam, and that Ray, in 1663, observed this kind of fuel at Liège (*Journey through the Low Countries*, &c., 1673, page 58), where they were called *hot shots*, serving to slake the heat of a fire and keep the coals from burning out too fast. We are informed that in some parts of Wales stone-coal culm is made into balls with clay, and is a common form of fuel in Pembrokeshire. The combustion is slow, and a long steady heat is kept up well adapted for lime burning. In 1853 a patent was taken out in England by M. Ducayla of Bordeaux for the manufacture of fireballs of such materials as cinders or ashes, wood or lignite, anthracite coal, pit coal, animal black, calcareous earth or clay, mould, &c.

---

[1] Hakluyt, in his *Voyages*, vol. i., p. 348, says, "we were forced to vse for fewell the dung of horses and camels, which we bought deare of the pasturing people." A substance in the form of long sticks, said to be made of camel's dung, is sometimes imported from the east under the name of *Chutnee*, and is occasionally used instead of the ordinary match for lighting pipes and cigars. It burns slowly without flame, and gives out an odour not unlike that of the burning cuttings of trees and shrubs.

[2] Sir Hugh gives an engraving representing a fire of fire-balls, without publishing a description of the method of making them; and he seems to have thought this so valuable that he offered to disclose it for a pecuniary consideration. His book is a curious exponent of the science of his day. It is entitled *The Jewell House of Arte and Nature*, and was published in 1594. The engraving referred to is contained in an appendix to the work, entitled *Divers Chimical Conclusions*, p. 69.

The fuel in every respect the most interesting to the British Islands, and one of the chief sources of their wealth and prosperity, is *coal*. The very abundance of this article causes it to be used in so lavish and extravagant a manner, that any general attempts to economise it and to fix its value as a fuel scarcely interest the public. There are, however, particular cases in which it is desirable to economise coal as far as possible, as in the case of a steam-ship of a thousand horse power, a single journey of which may require upwards of 2000 tons of coal, or more than 80,000 cubic feet. Hence it is obvious from the details given of the various descriptions of coal in the article COLLIERY, that some varieties of coal are better fitted for the purposes of steam navigation than others. A few years ago, when the government was establishing a steam navy, Sir H. de la Beche and Dr Lyon Playfair were requested to examine and report on the coal suited to the steam navy. The inquiry was conducted with great ability, and has resulted in two reports published in 1848 and 1849, which the reader interested in the subject will do well to consult. We will however state a few of the chief points elicited by this inquiry.

Bearing in mind the object of the inquiry, the commissioners considered that the chief test of the value of any coal submitted to their examination was its power of converting water into steam, so that if a given weight of coal in a certain time converted a larger proportion of water into steam than the same weight of another coal in the same time, the evaporative power of the one would be greater than that of the other. It was found, however, that the coal best adapted to steam-ships of war should also combine other qualities: for example, the fuel should burn quickly, so that steam may be raised in a short time; it should not be bituminous lest its smoke should betray the position of the ship when it might be desirable to conceal it; it should have such a cohesive power as not to be broken into fragments by the rolling motion of the vessel; it should have such a density and structure as to bear stowing away in a comparatively small space (a condition which in coals of equal evaporative value was found to involve a difference of more than 20 per cent.); lastly, the coal should not contain a large proportion of sulphur, nor be subject to rapid decay, or it might in either case lead to spontaneous combustion. But it was not found possible to unite all these conditions in the same coal. Anthracite, for example, has high evaporative power, but not igniting easily its action is not quick; it is not easily broken by the motion of the ship, but not being a caking coal, it would not cohere in the furnace, and would escape through the grate-bars during the rolling of the ship in a gale; it gives off no smoke, but from the intensity of its combustion it causes the iron of the grate-bars and of the boiler to oxidize rapidly; hence, with many advantages, anthracite has a few defects sufficiently prominent to preclude its use under ordinary circumstances. It was thought that a patent fuel might be formed with some of the anthracites of Wales, which should combine the advantages and elude the defects above referred to; but it was found that the cementing tar of the patent fuel burnt so much more rapidly in the furnace than the anthracite that the latter accumulated on the bars and obstructed the draught, or escaped through the grate unburnt.

In conducting this important inquiry, circulars were sent to the different collieries of Great Britain, explaining the object of the inquiry, and requesting the proprietors to forward two tons of coals for experiments; and in nearly all cases the application was favourably responded to. Each sample of coal was accompanied by a certificate from the owner, and in the report are given various particulars respecting the mine, the geological position of the coal, the method of working it, the nearest port, the extent of the trade in that coal, the physical character of the coal, together with the result of the experiments made upon it in a tabulated form.

One of the first experiments[1] on each coal was to test its cohesive power. This was done by enclosing a portion of coal in a wooden cylinder 3 feet in diameter, and about 4 feet in length, with a bearing or gudgeon at each end; within the cylinder were three shelves each 6 inches wide, tending towards the axis, for the purpose of forming a lodgment for the coals, and carrying them up towards the top of the cylinder during its revolution; thus ensuring a certain amount of fall. The coals to be tested were broken to the size used in the subsequent experiments on their evaporating power, and then thrown on a sieve with one-inch square meshes. 100 lb. of the coal left on the sieve were put into the cylinder which was made to revolve a certain number of times. The coals were afterwards sifted on the same sieve, and the weight remaining gave the percentage of large coals. The mean of two trials with each coal was taken, with fifty revolutions of the cylinder for each.

The coal was next heated under different arrangements of draught so as to ascertain when the gases escaping from the coal were most economically consumed. It was found that experiments made with highly bituminous coal, under different areas for the admission of air, varied much more considerably than the less bituminous coals of South Wales.

In testing the evaporative power of the coal a cylindrical boiler was used 12 feet in length and 4 feet in diameter, with flat ends, and an internal flue 2 feet 6 inches in diameter, in one end of which the grate was placed. The flues were on the split, or bridle draught plan, and the column of heated air after leaving the fire was made to pass through the internal flue to the rear of the boiler, where it divided, and returned along the outside of the boiler on both sides to the front; the two branches, each 2 feet 6 inches deep, then turned down at right angles to their former course, and united under the boiler in the bottom flue, traversed its whole length again and entered the base of the chimney, after exposing, during a course of about 36 feet, an area of 197·6 square feet of boiler surface to the heating action. The height of the chimney was 35 feet 6 inches, its internal dimensions being 182¼ square inches; it was furnished with dampers and with apertures for the purpose of making observations on the temperatures of the currents, and of obtaining samples of the gases for analysis, also for drawing up the soot. The furnace was closed with Sylvester's fire-doors, and a variety of ingenious arrangements were made for estimating temperature, pressure, &c. The method of conducting the experiments was as follows:—Supposing the water in the boiler to be cold, and to stand about one inch below the normal level, the fire was lighted, and the steam got up in the afternoon of the day preceding the commencement of the experiments. The fire was then allowed to burn out, when the fire and ash-pit doors and the damper were all closed. The next morning the first thing done was to open the safety-valve to equalize the external and internal pressures, and then sufficient water was let down from the tanks to raise that in the boiler to the normal level. The depth of the water in the tanks was then gauged, and the first observation of its temperature made. The ashes, cinders, and soot were next cleared out, and after noting the temperature of the water in the boiler, the fire was lighted with a weighed portion of wood, and the exact time was then observed. The coals were then gradually added till the fire was of the proper size and form. The form of fire was slightly varied according to the kind of coal employed, the object being to burn the coal to the best advantage with as little smoke as possible at the chimney. The observations of the temperatures of the two side and escape flues, and of the water in the tanks, then succeeded each other at regular intervals of about one hour each. When the steam raised the safety-valve the time was observed, and entered under the heading *steam up.* The damper was adjusted as soon as the fire was sufficiently established, and was not disturbed during the day, except under peculiar circumstances. When by evaporation the water had sunk about one inch below the normal level, the deficiency was supplied from the tanks above; or by the plan afterwards adopted, the water was allowed to flow in continuously, so as to maintain the water in the boiler at a constant level. The fire was supplied with coals, in pieces not exceeding 1 lb. weight each, and not more than one or two shovels full at a time, and were usually spread evenly over the fire; but in the case of anthracite, it was found that the sudden application of heat caused the pieces to split and fall through the bars. They were therefore gradually heated on the dead plate before being put on. With the bituminous coals a preparatory process of partial coking on the dead plate prevented them from coking in the fire (which would have impeded the passage of air through the grate), besides giving better opportunity for burning the smoke and gases by passing them over a large surface of ignited fuel. The duration of the experiment was reckoned from the time the steam was up to about that of the last application of fuel, after which the fire was allowed gradually to burn out, when the damper and furnace and ash-pit doors were closed. During the day ashes were thrown up in small quantities from time to time when the fire was burning clear and well. The weight of coals consumed was then ascertained, by deducting the weight left from the gross weight provided for the day's trial, when the experiment terminated. The next morning when the level of the water in the boiler was adjusted, by turning down a supply from the tanks, their depth was gauged, and the quantity evaporated the previous day was thus ascertained. The coke and cinders were then removed, the clinkers, if any, were separated, and the weight of each was taken. The soot was cleared out at the end of the last day's experiment, and the total weight recorded, which divided by the number of trials, gave the average weight. Samples of the ashes, cinders, and soot, were then put aside in bottles for the purpose of ascertaining the per-centage of combustible matter present in the residue. The barometer was observed at about 11 o'clock in the day, being generally about two hours after the steam was up. The quantity of combustible matter in the residue was estimated by heating the powdered substance in a stream of oxygen gas, by which the organic matter was got rid of chiefly in the form of carbonic acid and water, and the loss was estimated as combustible matter.[1]

---

[1] The experiments were conducted at the college for Civil Engineers at Putney by Professor John Wilson and Mr J. Arthur Phillips, assisted by other gentlemen.

The commissioners found that the qualities which distinguish particular kinds of fuel are very varied, so that it is difficult to deduce general results. But the data furnished by their experiments enable us to contrast the actual value of a particular coal with its theoretical value, supposing its combustion to be attended with no loss of heat. The actual duty obtained by 1 lb. of coal from the boiler employed may be expressed by the number of pounds raised to the height of one foot, a result which may be obtained by the formula $W\eta \times 965{\cdot}7 \times 782 = x$, in which W represents water, of which η pounds are evaporated by one pound of coal. This formula is deduced from the fact that η pounds of coal multiplied by 965·7, or the co-efficient for the latent heat of steam at 212°, indicates the number of pounds of water which would be raised 1° Fahr.; and the number 782 arises from experiment on the mechanical force denoted by the elevation of 1 lb. of water 1° Fahr.; that force being equal to 782 lb. raised to the height of one foot, according to the experiments of Mr Joule. The best Cornish engines are said to be capable of raising 1,000,000 lb. to the height of one foot for every pound of coal consumed, but this is only about $\frac{1}{8}$th of the actual force generated, and only $\frac{1}{11}$th or $\frac{1}{12}$th of the theoretical force. Experiments on the evaporative power of coal made by different observers give very dissimilar results. Smeaton in 1772 evaporated 7·88 lb. of water from 212° with 1 lb. of Newcastle coal; Wall in 1788 evaporated 8·62 lb; Wicksteed in 1840 evaporated 9·493 lb. of water from 80° with 1 lb. of Merthyr coal, which is equal to 10·746 lb. from 212°. In some experiments made at the united mines in Cornwall, it was found, after a trial of six months, that every pound of coal evaporated 10·29 lb. of water from 212°; and according to some experiments made in Cornwall, at the request of the commissioners, it was found that 11·42 lb. of water were evaporated by every pound of Welsh coal of similar chemical composition to that of Mynydd Newydd.

At ordinary temperatures coal undergoes a slow combustion under the action of the oxygen of the atmosphere, evolving carbonic acid, nitrogen, and inflammable gases, and in some cases leading to dangerous explosions. This slow combustion is facilitated by the higher temperature of hot climates, and by the presence of moisture. If the coal contain much sulphur or iron pyrites the chemical action may become so intense as to ignite the coals. In stowing coals it is therefore important that they should be as dry as possible, and such a variety should be selected as is least liable to this progressive decomposition. When coal is kept in iron bunkers, and is liable to be wetted with sea water, the iron rapidly corrodes from the carbon or coal forming a voltaic circuit with the iron, and thus promoting oxidation.

In the Great Exhibition of 1851, Messrs Berard and Co. in the French department, No. 51, exhibited "small purified coals, and residue of the same, the produce of a system for purifying coals, patented in France, England, Belgium, and Germany." This plan appears to be well adapted to the purification of sulphurous coal, or coal containing much iron pyrites; also where the coal deposits are in numerous small seams, and cannot be got out without being mixed with slaty and stony matter. The coal used on the Chemin de Fer du Nord was so sulphurous as to injure the locomotives; but by using the purified coal, the evil was for the most part remedied; the quantity of ash was also greatly reduced. The apparatus employed for purifying the coal is similar in principle to the jigging machine used in dressing ores, which, after being stamped in order to separate stony matter, are agitated in water and allowed to rest, when the various portions become arranged in layers, according to their specific gravities. This purified coal yields a very pure coke.

Mr Crace Calvert of Manchester has taken out a patent for purifying coke from sulphur. It consists in mixing the coal before coking with from 1½ to 2½ per cent. of common salt, the proportion varying with the quantity of sulphur. The coking is then conducted as usual. By this contrivance, coal, which was formerly unserviceable in smelting operations, can now be used with effect.

We cannot conclude this article without a brief notice of some of the earlier attempts to ascertain the heating value of fuel. The economy of manufactures, our domestic arrangements, health and comfort, depend so much on the judicious application and regulation of fuel, that any information tending to its better expenditure ought to command attention. Our expenditure of coal is of so prodigal a nature, and is every day so increasing, that we look forward to the time when the supply may fail. The calculations made many years ago by geologists on the probable duration of our fossil fuel were not only based on incorrect data, but on a comparatively small consumption. The ten-yard coal of Dudley is nearly exhausted, and other districts are becoming more scanty in their supplies, or more difficult to work.

---

[1] *Report*, p. 21, 22, slightly abridged.

As various kinds of fuel afford different amounts of heat, and as heat cannot be measured or weighed, and its quantity ascertained by direct experiment, the relative values of fuels are ascertained by comparing them with each other under similar circumstances. The heating power of a fuel is the quantity of effect produced by it in a certain time, and this in conjunction with its market price gives its value as a fuel. One fuel may produce a certain greater or less effect than another fuel, and thus its relative superiority or inferiority may be accurately ascertained, although the actual amount of heat furnished by it may be entirely unknown. Lavoisier and Laplace fixed these values by making the substance under examination act on ice, and the quantity of ice melted gave the value in each case. Count Rumford measured the value of fuel by the increased temperature which it produced in a given quantity of water. Now, as the same quantity of heat which melts one pound of ice at 0° Cent. is sufficient to raise the temperature of as much water 79° Cent., or 0·79 lb. of water 100° Cent., so also an equal weight of aqueous vapour of any given temperature and elasticity is always formed from the same amount of heat, and always contains the same quantity of heat, and the quantity of heat which water at 100° Cent. renders latent in order to become steam is 5·5 times sufficient to heat the same weight of water from 0° to 100° Cent., hence the water converted into vapour by the heat required to melt one pound of ice is the 5·5th part of the same pound, that is, it can convert into vapour 0·154 lb. of water.

It was found by Despretz and Welter that the quantities of fuel which require equal amounts of oxygen for combustion, give out equal quantities of heat, thus, 1 lb. of oxygen in combining respectively with hydrogen, charcoal, alcohol, &c., raised 29 lb. of water from 32° to 212°. A given weight of the different combustibles has its heating power represented by the number of pounds of water raised in temperature, as in the following table:—

		lb. of water.		
1 lb. of	pure charcoal raised...	78	from 32°	to 212°.
...	common wood charcoal	75	...	...
...	baked wood...............	36	...	...
...	wood holding 20 per cent. of water.........	27	...	...
...	bituminous coal.........	60	...	...
...	turf........................	25 to 30	...	...
...	alcohol....................	68	...	...
...	oil, wax..................	90	...	...
...	ether......................	80	...	...
...	hydrogen..................	236	...	...

More recent researches have, however, cast considerable doubt upon the law that any given quantity of oxygen evolves the same quantity of heat with whatever combustible body it may combine. From a series of tabulated results given in Gmelin's *Hand-Book of Chemistry*, vol. i., page 292 (Cavendish Society's translation), it would rather appear that oxygen developes a larger quantity of heat the stronger its affinity for the combustible substance

Such experiments as the above tend to confirm the modern view of combustion which regards oxygen as a combustible as much as the fuel with which it combines (see CHEMISTRY, vol. v., page 456); so that when oxygen burns by means of any fuel, the heat evolved increases with the quantity of oxygen consumed. It was on this view that Berthier based his process for detecting the quantity of oxygen required for combustion, and the heating power of the combustible in one experiment. His plan is to heat to redness a known quantity of the combustible with a considerable excess of pure litharge until the combustible is entirely consumed by the oxygen of the oxide of lead. On weighing the lead reduced by this process the amount of oxygen consumed is ascertained, and also the heating power of the fuel under examination. In calculations of this kind it will be remembered that 6 parts, or 1 equivalent of carbon, require 16 parts, or 2 equivalents of oxygen, for combustion; that one part of hydrogen requires 8 parts of oxygen; that by subtracting from the hydrogen a quantity corresponding to the oxygen in the coal, the calculation can be made for the carbon only. Now, 1 part of pure carbon requires for combustion 2·666 of oxygen, and is capable, according to Despretz, of heating 78·15 parts of water from freezing to boiling. By multiplying each part of lead obtained by 2·265, the weight of water is obtained which is capable of being heated between these temperatures by a unit of the coal used in reducing the litharge.

The heating power of a particular fuel is the same, however that fuel may be burnt. It is true, that the power may be more or less economically applied; the power may be expended with greater or less rapidity, greater, for example, in a furnace than in an open grate, but as the fuel during combustion combines with equivalent portions of oxygen, the same amount of heat is liberated whether the combination be rapid or slow. The rapidity of combustion depends not only upon the mode of arranging the draught or supply of air to the fuel, but also on the state of division of the fuel itself. A given weight of wood in the state of shavings will, from the large extent of surface exposed, burn rapidly, and produce its full heating effect in a few minutes, while the same weight of wood, in the form of a log, may keep up a moderate temperature for some hours. The division of a fuel may, however, be carried so far that the air necessary for its combustion cannot penetrate it. Such is the case with saw-dust, powdered charcoal, or peat, slack coal, &c. If the powdered coal be of caking quality it may be burnt into compact coke, and thus be more useful than a fuel which in its first form is compact but which falls to powder on being heated in the furnace. Small fuel may sometimes be advantageously applied by covering the furnace-bars with pieces of sand-stone or lime-stone for the purpose of preventing the fuel from falling through, and for distributing the supply of air among it. In the roasting of copper ores in South Wales a flaming coal is necessary in the reverberatory furnace where the operation is carried on. But as the flameless anthracite is much more abundant in this district than the bituminous coal, it is turned to account in an ingenious manner. When burnt under ordinary circumstances it crumbles to powder, as already noticed, and either slips through the bars of the grate, or chokes them up. But when anthracite is raised to a very high temperature it forms a vitreous scoria or clinker, which in the ordinary furnace combines with the iron of the bars and chokes up the grate. In the Welsh furnaces the clinkers themselves are ingeniously arranged, so as to perform the office of grate bars, namely, to support the fuel, and to limit the supply of air from below. The clinkers are supported on iron bars placed at a considerable distance apart, and are arranged in a layer twelve or sixteen inches in depth. Above this layer the fuel of the furnace is in full combustion: this fuel consists of anthracite mixed with about one-fourth of its weight of small bituminous coal, and also forms a layer of a depth about equal to that of the clinkers; it is in this the hottest part of the fire that fresh clinkers are being continually formed, and while forming they cake with the numerous fragments of bituminous coal heaped up above them. As fresh portions of the fuel come into operation the clinkers descend towards the bottom of the grate, where meeting with the numerous jets of air which stream up through the bottom the vitrified mass splits and cracks in all directions, forming new channels for the ascent of the draught, but not large enough to allow the small coal to escape. As the calciner-man heaps up fresh fuel above, he hooks out a few clinkers from the bottom to make way for the descent of others. Under this arrangement the oxygen of the air traversing the multitude of channels formed by the cracks in the clinkers, combines with a portion of the fuel and forms carbonic acid, which is uninflammable, but before reaching the vault of the furnace it is deprived of a portion of its oxygen, and becomes converted into carbonic oxide, which is inflammable. But in order that this gas may undergo combustion, air is admitted through apertures in the sides of the furnace just above the ore, and in this way the whole surface of the ore, occupying an area of nearly 23 feet square, is played upon by a thin sheet of flame, produced from fuel which gives scarcely any flame at all.

Common coal gas is sometimes used as fuel, in which case it is calculated that 1 lb. or 24 cubic feet thereof in burning will raise 76 lb. of water from the temperature of freezing to that of boiling. Extending this comparison to the other forms of fuel, it is stated that 1 lb. of dry wood will similarly heat 35 lb. of water, but only 26 lb. if the wood be not dry, or contain moisture to the extent of from 20 to 25 per cent. One lb. of good dry charcoal will similarly heat 73 lb. of water, but if exposed to the air it absorbs at least 10 per cent. of moisture, and in burning gives a flame of carburetted hydrogen (or rather, probably, a mixture of carbonic oxide and hydrogen), arising from the decomposition of the moisture. One lb. of good pit coal is said to raise 60 lb. of water from freezing to boiling, 1 lb. of coke 65 lb., and 1 lb. of turf or peat from 25 to 30 lb. (C. T.)

FUENCALIENTE, a town of Spain, in the province of La Mancha, and archbishopric of Toledo. It is 50 miles from Ciudad-Real, contains 1799 inhabitants, and is situated in the middle of the Sierra Morena, to the S. of Madrona and Quintana, its two principal summits. The baths of Fuencaliente (" hot spring") are very much frequented by those afflicted with paralytic and rheumatic complaints. The mountains abound with excellent pasture for goats, with numerous fountains and mountain torrents of wholesome water; its forests abound with oaks, arbutuses, wild rose-trees, and heath, and with numerous olive and fruit trees.

FUENCARRAL, a royal town of Spain, in the province of Madrid and archbishopric of Toledo, and containing 1890 inhabitants. It is situated about 5 miles N. of Madrid, and contains one convent of Dominicans, situated without the walls, and called Valverde, founded in 1598 A.D., on the site of an ancient hermitage. Fuencarral is the birthplace of Ramon Montero, bishop of Heliopolis. It produces grain, oil, grapes, red wine, and abundance of garden stuffs for the Madrid market. Its principal manufactures are oil, soap, and some wool.

FUENLABRADA (DE LOS MONTES), a secular town of Spain, in the province of Estremadura, and 120 miles from the capital. It has a population of 2027, and is situated on a hill planted with evergreen oaks, rock-roses, sweet mastiches, and arbutuses. The climate is very delightful and healthful, and the water excellent. The principal productions are game, honey, wax, corn, vetches, oil, herbs, flax, excellent wine, and all kinds of cattle and sheep. The principal manufacture is linen, but only for domestic use.

FUENLABRADA, a royal residence of Spain, in the province of Madrid and archbishopric of Toledo. It is governed by an alcalde; contains 1725 inhabitants; and is situated in an extensive open plain, about 10 miles from Madrid. The chief products are grain and wine; and the industry is mostly confined to the rearing of cattle and grinding of corn for sale. It is the native place of Felix Herrero Valverde, bishop of Oribuela.

FUENMAYOR, a royal city of Spain, in the province of Soria. It has a population of 2285, and is situated in a vast plain a short distance from the Ebro, on a small river which divides the town into two equal parts and falls into the Ebro. This stream has no name, and except in winter contains scarcely any water; but the springs are good and abundant. The principal products at Fuenmayor are wine, grain, and garden produce of every variety; but that which commands most attention is its excellent capsicums, so much sought after over all the peninsula, as well for their flavour as for their large size, some of them weighing 1½ lb.; the average size, however, is about the half of this. The average annual sowing produces about 1,500,000 plants. Besides these, every kind of fruit abounds around Fuenmayor, and large quantities of oil are manufactured.

FUENSALIDA, a secular town of Spain, in the province and archbishopric of Toledo. It is 40 miles from Madrid, and contains 2739 inhabitants. The situation is on an elevated plain, agreeable, and very beautiful; the temperature mild and equable; and the water abundant and wholesome. Around Fuensalida are produced wheat, barley, beans, kidney beans, vetches, tares, apples, grapes, and some olives. The principal manufacture is soap, the people around being mostly engaged as labourers and carriers.

FUENSANTA, a royal town of Spain, in the province and bishopric of Cuenca. It contains 1831 inhabitants, and is situated in a valley on the bank of the Jucar, which flows from N. to S. The soil around the town is sandy and gravelly, and well adapted for vines and olives, which are very abundant here, but so badly cultivated that the produce is very small. The same may be said of the orchards. Yet saffron, truffles, and some garden stuffs, are produced in abundance. The only manufacture is bass-matting.

FUENTE-ALAMO, a royal town of Spain, in the province of Murcia. It contains 2653 inhabitants, and is distant 30 miles from Murcia.

FUENTE-CANTOS, a royal city of Spain, in the province of Estremadura. It contains 5000 inhabitants, and is 48 miles S.E. of Badajoz. It stands at the foot of a chain of mountains, and is beautifully situated on an extensive and elevated plain, from which there extends a magnificent prospect in all directions. All kinds of fruit, grain, and vegetables abound around Fuente-Cantos; and the wine and water are of the best quality. The principal and almost the only manufacture is frieze.

FUENTE-DE-LEON, a town of Spain, in Estremadura. It contains 4000 inhabitants, and is 50 miles S. from Badajoz. There is a silver mine of some importance in its vicinity.

FUENTE-DEL-MAESTRE, a town of Spain, in the province of Estremadura. It is distant 40 miles from Madrid, contains 1580 inhabitants, and is situated between Almendralejo and Zafra on the main road from Madrid to Sevilla, by Merida on the skirt of the Sierra de San Jorge. From it spreads out an extensive open plain planted with groves of olives, which yield abundance of oil, without in any way injuring the corn and the vine crops, and abundant pastures for every species of flock and herd.

FUENTE-DEL-SAUCO, a town of Spain, in the province of Zamora. It is 24 miles S.E. of Zamora, in a fertile valley, and contains 2557 inhabitants. The streets are straight and wide; and it contains a custom-house, two churches, two hospitals, two public squares, and has several distilleries of brandy.

FUENTE-EL-FRESNO, a town of Spain, in the province of La Mancha and archbishopric of Toledo. It is situated on elevated ground at the foot of a low chain of hills on the royal road from Madrid to Ciudad-Real, from the latter of which it is distant 24 miles N.N.E., and contains 2315 inhabitants. Near this town is the cave Montesinos, into which Cervantes makes Don Quixote descend.

FUENTE-LA-HIGUERA, a secular city of Spain, in the province and archbishopric of Valencia. It contains 2659 inhabitants, and is situated 44 miles N.W. of Alicante, on a rock at the foot of a calcareous mountain, and at the entrance of a beautiful valley, over which it looks. This valley is interspersed with orchards, forming an uninterrupted series of landscapes, terminated by the declivities of the mountains which surround it, and are cultivated to the very summits. The chief produce is wheat, barley, wine, and timber. At Fuente-la-Higuera Jourdan, Soult, and Suchet, after the rout of Salamanca, met with their retreating forces, and held a council how best to get back into France, when Ballesteros, by refusing to obey Wellington's orders, opened the way for them to Madrid, in October 1812.

FUENTE-OBEJUNA (Fons Mellaria), a royal town of Spain, in the province and bishopric of Córdoba. It is 50 miles N.W. of the city of Córdova, contains 5500 inhabitants, and stands on the crest of a hill, with the Colegiata on the apex, like an acropolis. The "Honey Fountain" is at the bottom of the hill to the W., and coal seams occur here which extend to Villaharta. Fuente-Obejuna stands in the immediate neighbourhood of the Sierra Grana, and had its ancient name, *Fons Mellaria*, from the abundance and superior quality of the honey produced here by the bees so well supplied by the heath of the surrounding hills. The three rivers, Guadiato, Suja, and Bembezar, which flow along its boundaries, abound in fish of excellent quality. The neighbouring pastures are rich and abundant, while the wine, though very good, is small in quantity. Fruits and vegetables are plentiful; and every kind of game, from the wild boar to the rabbit, is very abundant. Herds and flocks abound also, as well as honey, wax, wheat, barley, and most other cereals. There are in the vicinity mines of various kinds of metal, and also of talc and coal. Its industry consists principally in the manufacture of linen fabrics and hides, frieze and baize; besides the distillation of various kinds of spirits. The arms of Fuente-Obejuna consist of a fountain with four spouts surmounted with a swarm of bees, and in the lower part of the escutcheon a castle, with its towers and armoury, from which rises a red banner with a cross, and in the sinister two lions in the attitude of springing upon a sheep (*obeja*, or *oveja*).

FUENTEPELAYO, a secular town of Spain, in the province and bishopric of Segovia. It stands 19 miles N. of Segovia, and contains 1640 inhabitants. It is situated on an elevated and beautiful plain, which produces in abundance wheat, barley, rye, tares, vetches, and some wine of inferior quality, and scarcely sufficient for local consumption. The principal industrial products are,—coarse sacking, grogram, with some other coarse materials for local wear. Considerable quantities of sheep and wool, of various kinds, are produced and sold in the neighbouring large towns.

FUENTERABIA (generally, but erroneously, written Fuenterrabia), a very ancient city of Spain, in the province of Guipúzcoa, and bishopric of Pamplona, and 12 miles E.N.E. of San Sebastian. It stands on the W. bank of the Bidasoa, on the slope of a hill which has the form of an amphitheatre. It is still fortified, and has a population of only 2134. The greater part of the city, however, is little else than a collection of ruined mansions, with ornamented roofs projecting over dilapidated balconies, ivy-covered battlements and broken walls, gateways, and towers. The circuit of the wall of Fuenterabia is nearly two English miles, and it is encircled from the N. by the W. and S., with a broad ditch, and defended on the E. by the river Bidasoa and its estuary. The wall and its defences are now in a much dilapidated state. The four quarterings of the arms of Fuenterabia bear an angel holding a key, a whale, two syrens, and a castle between two stars, which were bestowed by Philip IV. in 1638, when the Prince of Condé was here repulsed by the Admiral of Castile. In 1794 the French completely dismantled the place; and the inhabitants, during the winter, begrudged even lodging to the English sick soldiers, from whom the authorities of the city wished to take away even the hard boards on which the disabled were stretched; "and these," said Wellington, "are the people to whom we have given medicines . . . whose wounded and sick we have taken into our hospitals, and to whom we have rendered every service in our power, after having recovered their country from the enemy" (Nov. 27, 1813). Fuenterabia is the native place of Cristobal de Rojas y Sandoval, chaplain to Charles V., and bishop of Oviedo, of Badajos y Córdova, and archbishop of Sevilla, who assisted at the council of Trent.

FUENTES-DE-DON-BERMUDO, a town of Spain, in the province of Valencia, and 12 miles W.N.W. of the city Palencia. It is situated in a plain on the N.W. bank of lake Nava, and contains a population of nearly 3000. The country around produces immense quantities of grain and excellent wine, which is one-third more valuable than that produced in the neighbouring districts. Immense flocks and herds are kept in the vicinity of Fuentes-de-don-Bermudo; and the industry consists principally of the manufacture of bolting cloth, to the annual amount of 24,000 pieces of 80 yards each, which is sent chiefly to Asturias. Large quantities of cheese are also produced for exportation.

FUENTES-DE-EBRO, a secular town of Spain, province of Aragon, and archbishopric of Zaragoza. It is on the right bank of the Ebro, and contains a population of nearly 2000. It contains a saline mineral spring, which has not yet been analysed. The principal branch of industry is the manufacture of serge of various coarse kinds. Its arms are five silver castles on a field of red.

FUENTES-DE-LA-CAMPANA, a secular town of Spain, in the province and archbishopric of Sevilla. It contains 9000 inhabitants, and is situated on a hill about 4 miles from the road, which is between Ecija and Carmona. The town is very ancient, and contains many Roman and Saracenic antiquities. It has a custom-house, an hospital, a church, and two convents. The situation is exposed to winds from all directions, and the temperature is dry and cold.

FUENTES-DE-LEON, a town of Spain, in the province of Estremadura. It is 5 miles from Segura-de-Leon, and contains 2920 inhabitants. It is situated in a territory so rugged, that to a distance of 20 miles there is no road for wheeled vehicles. In the vicinity great numbers of pigs are reared, and pork is exported in large quantities. The annual produce of oil is about 20 tons, of wheat 4000 bushels, and of rye 1000. The principal industry of the inhabitants is in the tending of the herds and flocks of the Sierra de Aracena. There is one silver mine in the neighbourhood.

FUENTES-DE-ONORA, a town of Spain, province of Salamanca, in a mountainous district, 16 miles W. of Ciudad-Rodrigo, and near the left bank of the Rio das Casas, on the frontier of Portugal. In 1811, this was the scene of several battles between the English and the French; but especially on March 5, between Wellington and Massena.

FUEROS are certain immunities constituting what may be termed the Magna Charta of that part of Spain known as the Basque Provinces, namely Guipúzcoa, Alava, Biscaya, and Navarra. The term is probably derived from the Spanish *fuera*, outside, indicating that these provinces are without the pale of the ordinary administration of the Spanish monarchy.

The *fueros* differ as to their details in the different provinces; but the main features are the same in all, the form of government being essentially republican, and the royal authority only nominal. Taking the province of Biscay as an example, we find that the only prerogative of the crown is that of nominating the corregidor, or highest officer of the state; and that even this nomination is subject to the approval of certain members of the junta or states, in which is vested the chief management of public affairs. The junta is the most popularly constituted representative body existing in modern times, excepting the American congress. The right of voting in the election of its members belongs to every man who is master of a dwelling within the lordship, and its functions include the general administration of the affairs of the commonweath, the collection of taxes, the protection and defence of the territory, and the nomination of all the officers of government, except the corregidor. The inhabitants of the province are exempt from all imposts except the self-imposed ones of their own locality, and from all duties on imported merchandise. They claim the privileges of Spanish nobility on merely proving their descent from pure Biscayan blood. They are not obliged to appear before any tribunal beyond the bounds of their own lordship, or to tolerate any royal intendant or comptroller within the province, or to allow any royal monopoly as in the rest of Spain, or have any royal establishment except the post-office, or admit royal troops within the territory, or furnish recruits for the royal army. But they are privileged to defend their territory with their own means and their own blood; and moreover to visit with summary punishment whoever may attempt even to interfere with these their constitutional rights.

The history of the *fueros* is lost in their profound antiquity; but they are believed to date from the brave Cantabrians who were never completely subjugated to the Roman yoke, and who, even when partially conquered, maintained their own laws and customs inviolate. Whether this was the origin of the fueros, or not, it is certain that from time immemorial the Basque provinces have enjoyed certain privileges unknown throughout the rest of the Spanish dominions. They existed only in the traditions of the country, and seem nevertheless to have been well understood and observed till the year 1235, when, in consequence of the accession of a French prince to the throne, some misunderstanding arose, and it was deemed necessary to embody these privileges in a written code. The charter thus framed was enlarged under the sanction of Charles V., and was recognised as the Magna Charta of the Basque provinces till the revolution of 1833, when its maintenance became the occasion for a series of sanguinary hostilities which devastated Spain for several years. These struggles terminated only when the Spanish government and the Cortes entered into a formal recognition of the rights, privileges, and ancient customs of the Basque provinces.

FUGALIA, in *Roman Antiquity*. See REGIFUGIUM.

FUGLEMAN (Germ. *flügel*, a wing), a non-commissioned officer who is placed in front of a regiment at drill to guide the soldiers in the movements.

FUGUE, in *Music*. See MUSIC.

FULCRUM, in *Mechanics*, the prop or support by which a lever is sustained. See MECHANICS.

FULDA, one of the four provinces of the electorate of Hesse-Cassel, comprising the greater part of the ancient independent bishopric of Fulda, and the isolated circle of Schmalkalden. The bishopric of Fulda originated in an abbey founded by St Bonifacius in 744. It subsequently received various privileges, and in 1752 was raised to the rank of an independent bishopric. In 1803 it was secularized and ceded as a principality to the Prince of Nassau-Orange; and in 1810 it was incorporated by Napoleon with the grand-duchy of Frankfort. In 1814 it was divided, a district containing 27,000 inhabitants being given to Saxe-Weimar, and the rest to Prussia. Prussia afterwards ceded her portion to Hesse-Cassel, and it now forms one of the provinces of that electorate. It has an area of 720 square miles, and in 1846 contained 140,713 inhabitants.

FULDA, the capital of the above province, is situated on the river of the same name, 54 miles S. of Cassel. The Fulda rises in the Rhön-Gebirge, and after a northward course of about 90 miles, unites with the Werra below Munden to form the Weser. Fulda is a walled town, pleasantly situated and generally well built It is the seat of a superior court of justice and of a Roman Catholic bishop, whose jurisdiction extends over the whole electorate. The cathedral, containing the tomb of St Boniface, and the bishop's palace, with its extensive garden, are the chief of its fine buildings. The university founded here in 1734 has been converted into a lyceum. Fulda has also several monasteries, hospitals, asylums, and seminaries, a public library, and manufactures of linens, woollens, tobacco, leather, &c. The river is here crossed by a handsome stone bridge. Pop. (1845) 9570.

FULHAM, a village or suburb of London, on the left bank of the Thames, here crossed by a wooden bridge, 5½ miles S.W. of St Paul's. It contains numerous handsome houses and villas, and the vicinity is chiefly laid out in market gardens. The bishop of London has a palace here. Pop. of parish (1751) 11,816.

FULLER, REV. ANDREW, a distinguished preacner and theological writer of the Baptist denomination, born Feb. 6, 1754, at Wicken, a village in Cambridgeshire, about seven miles from Newmarket. He received the rudiments of his education at the free school of Soham. His father was a small farmer, whom he assisted as soon as he was able, till he was twenty years old. In childhood and youth he indulged in profane language and in lying, but was remarkably free from the vices of licentiousness. He had, however, strong "compunctious visitings" which never left him (some brief intervals excepted), till he was completely brought under the influence of Christian principle. He has left on record an interesting account of the commencement and progress of his spiritual life, which was greatly impeded by the contracted views of the religious people among whom he was brought up. His moral and intellectual nature was, however, composed of strong elements, and worked its way through formidable obstacles; no doubt, much of the strength and vigour it afterwards displayed was owing to the struggles and conflicts of his early manhood, or as he called them, "the gall and wormwood of his youth." In his seventeenth year he became a member of the Baptist church at Soham, and in the course of four years, after giving proofs of his abilities for public speaking, he was chosen to the pastoral office, which he filled for more than seven years, receiving from three different sources a stipend of only L.21 *per annum*, which he endeavoured to eke out, first by a small shop and afterwards by a school, in order to maintain himself with a wife and four children. In 1782 he removed to Kettering, in Northamptonshire, after a protracted deliberation of not only months but years, from a scrupulous dread of forsaking the path of duty, though with the prospect of absolute poverty if he remained. His conduct on this occasion (it has been justly said), "exhibits the rare spectacle of a man capable of making any sacrifice of selfish interest to his sense of duty to God and to his fellow-mortals." In his new position he was brought into frequent intercourse with several eminent ministers of his own denomination (among whom were Robert Hall and his venerable father), some of whom had enjoyed greater advantages of education than himself—who, though of characters in many points strikingly diverse, were men of deep piety, and addicted to theological inquiries. At that time the Calvinism prevalent in the Baptist denomination was mingled and overlaid with many crudities which the Genevan reformer would have disowned as foreign to his system. The writings of the great transatlantic divine Jonathan Edwards had just been introduced into Britain principally through the medium of Dr Erskine of Edinburgh; these were studied with avidity by Mr Fuller and his associates, and contributed largely to the correction and enlargement of their religious views. Before leaving Soham, Mr Fuller, then in his twenty-sixth year, had written a treatise entitled, *The Gospel worthy of all Acceptation*, which was designed to counteract those Hyper-Calvinistic notions which had perplexed his own mind. This he sent to the press soon after his settlement at Kettering, and was involved by it in a controversy with writers who differed as much from one another as from himself. But the works on which his reputation as a theologian mainly rest are two; the first published in 1793, *The Calvinistic and Socinian Systems Examined and Compared as to their Moral Tendency*, which was attacked by Dr Toulmin and Mr Kentish, to whom Fuller replied in a pamphlet entitled, *Socinianism Indefensible on the Ground of its Moral Tendency*. His second important work appeared in 1800, *The Gospel its own Witness; or the Holy and Divine Harmony of the Christian Religion contrasted with the Immorality and Absurdity of Deism*. These two treatises have lately been reprinted, with a memoir by the author's son, and form a volume of Bohn's Standard Library. Fuller also published *Expository Lectures on Genesis*, and prepared a similar volume (though not of equal interest), on the Revelation, which was published after his death. His *Memoir of the Rev. Samuel Pearce of Birmingham* will always hold a high rank among religious biographies. The greater number of his works are small in bulk, being chiefly single sermons or pamphlets, but in their last collected form fill 1000 pages royal 8vo. They all bear the stamp of a masculine, acute, and logical intellect; they are the productions of a man who thought for himself; who was deeply impressed with the majesty and worth of religious truth, and who when, after earnest search, he believed himself to possess it, held the conclusions he had reached with an unflinching tenacity. But the productions of his pen constitute only a portion of the labours of his life: he was not less a man of action than of meditation. In the year 1792 the Baptist Missionary Society was formed at Kettering by thirteen individuals, of whom Fuller was one. He was appointed secretary, and some of the brightest and palmiest days of the Society were under his administration, adding one more to the innumerable instances of the advantages (with some drawbacks) resulting from a scheme of operations being placed under the direction of one master-mind. "Friends talk to me" (he once remarked to a confidential friend), "about coadjutors and assistants, but I know not how it is, *I find a difficulty*. Our undertaking to India really appeared to me on its commencement to be somewhat like a few men who were deliberating about the importance of penetrating into a deep mine which had never before been explored. We had no one to guide us, and while we were thus deliberating, Carey, as it were, said, 'Well, I will go down, if *you* will hold the rope.' But, before he went down, he, as it seemed to me, took an oath from each of us that while *we* lived *we* should never let go the rope. You understand me, there was great responsibility attached to us who began the business, and *so I find a difficulty*." The correspondence he maintained; the journeys he undertook (among which were five to Scotland, and one to Ireland); the pamphlets he wrote in its defence, and the discourses he preached on its behalf, a frame less robust, physically and mentally, than his could not have sustained, and *his* frame at last sank under these complicated and unremitting toils. He died May 7, 1815, in his sixty-second year.

In private life, Fuller's character was marked by unbending integrity; and notwithstanding a certain uncouthness and sternness of manner, he had a heart capable of ardent and self-denying friendship, and of the tenderest affection in the domestic circle. His judgments of other men might often lean to the side of severity, but it must be recollected that he never spared himself. By one who knew him well and revered his character (the late Robert Hall), he was thought to attach too much importance to a speculative accuracy of sentiment, and to be too prone to infer the character of men from their creed; yet, in extenuation, it may be alleged that *his* creed was no mere formula of articles of faith, it was the perennial feeder of his moral and religious life; what wonder then that he attached a similar importance to the avowed belief of others?

It is a proof of the estimation in which Fuller's writings are held, that there have been three collected editions of them, besides American reprints. The first in ten 8vo vols.; the second in five; and the last in one royal 8vo. A memoir, principally compiled from his own papers, was published about a year after his decease by his most intimate friend and coadjutor in the affairs of the Baptist mission, the late Dr Ryland of Bristol; a second edition, with corrections and additions, appeared in 1818. A second biography, with a critical notice of his writings, was written by the Rev. J. W. Morris; and a third was prefixed by his son, the Rev. A. G. Fuller, to the second and third editions of his works. With some additional matter, it appears to be based on Dr Ryland's memoir. In the second volume of Coleridge's *Notes on English Divines* (London 1853), are a few marginalia on the "Calvinistic and Socinian Systems compared," pp. 238–243. (J. E. R.)

FULLER, Thomas, one of the wittiest and most original divines of the English Church, was born in 1608 at Aldwincle in Northamptonshire. His father, who was minister of St Peter's Church in that village, conducted his education personally, and so well that Fuller was admitted of Queen's College, Cambridge, in his thirteenth year. In 1624 he took his degree of B.A., and four years later that of M.A. Shortly after taking orders, he was chosen minister of St Bennet's, Cambridge, where he attained great popularity as a preacher. In 1631 he was chosen fellow of Sidney College, and made a prebendary of Salisbury. This year is also memorable in his life as that which witnessed his maiden publication. It was a poem—now extremely scarce—entitled *David's Heinous Sin, Hearty Repentance, and Heavy Punishment*. Shortly after this he was presented to the rectory of Broad Windsor in Dorsetshire, where, as one of his biographers remarks, "he began to complete several works he had planned at Cambridge." To complete his happiness he married about this time, but had the misfortune, in 1641, to lose his wife after she had given birth to a son. Wearied with the monotonous routine of rural life, and anxious to be near the principal scene of public affairs, Fuller repaired to London, where his fame as a pulpit orator secured for him the lectureship of the Savoy. In 1640 he published his deservedly celebrated *History of the Holy War*, which brought him in both money and a great increase of repute. He was a member of the Westminster Convocation of 1640, and has left an interesting account of its proceedings in his *Church History*. In 1642 he preached a sermon in Westminster Abbey which gave great offence to the Parliamentarians. The day happened to be the anniversary of the king's inauguration, and the preacher chose for his text the words, "Yea, let him take all, so that my lord the king return in peace." The sermon, which was in the same loyal spirit as the text, involved the preacher in no little odium with the Puritan party. In the same year Fuller published his most popular and in some respects his best work, entitled *The Holy and Profane State*. Declining, on grounds of conscience, to take the oath to Parliament, he now left London and joined the king at Oxford. His majesty was desirous to hear him preach, and Fuller immediately obeyed the royal order, but so little in the spirit of a partizan that the king was disgusted and the royalist party indignant at his calm moderation. His neutral policy was singularly ill-adapted for these troublous times, and he was soon to feel in a manner to him exquisitely galling the rancour of party spirit. Sequestration was pronounced against him, and embittered by the loss of all his books and manuscripts. Two royalist noblemen, Lord Beauchamp and Cranfield Earl of Middlesex, generously repaired this misfortune by making over to Fuller such remains of their private libraries as had escaped the ravages of the civil war. Induced to identify himself with the royal cause, and anxious to clear himself of the charge of lukewarmness, he sought and obtained, through Sir Ralph Hopton, a chaplaincy in the king's army. This office put at his disposal a good deal of time, which he turned to account by collecting materials for his *Worthies of England.* His numerous marches and countermarches through the country enabled him to amass many valuable details which might otherwise have been lost. Having espoused the royal cause, he threw himself into it with vigour, and gave a memorable proof of his zeal in the defence of Basinghouse, when he was besieged there with a small party of royalists. For he animated his little garrison to so vigorous a defence that the parliamentary commander, Sir William Waller, was obliged to retire from the place with loss. When the royal forces were afterwards driven into Cornwall, Fuller took refuge in Exeter, where he preached regularly to the citizens. About this time he was appointed chaplain to the infant princess, Henrietta Maria, and presented to the living of Dorchester. During his stay at Exeter he is said to have written his work entitled *Good Thoughts in Bad Times.* When at length the town surrendered to the Parliament, Fuller repaired to London, where he found his Savoy lectureship occupied by another, but readily obtained in its room that of St Clement's, and subsequently of St Bride's. His appointment to these offices, however, was merely nominal, as he was "forbidden (to use his own language) till further order the exercise of his public preaching." This rigour, however, did not prevent the Earl of Carlisle from offering him in 1648 the rectory of Waltham Abbey in Essex. In this same year he published at Cambridge his *Holy State*, and two years later at London his *Pisgah-sight of Palestine and the Confines thereof, with the History of the Old and New Testaments, acted thereon.* His literary history of the next two or three years exhibits nothing beyond a few tracts and sermons of temporary interest, which have been long forgotten. In 1654 he married a lady of noble family, the sister of Viscount Baltinglass, and in the following year made himself notorious by persisting in the discharge of his ministerial functions, "notwithstanding Cromwell's prohibition of all persons from preaching or teaching schools who had been adherents of the late king." In this year also he published his *Church History of Britain from the Birth of Jesus Christ until the year MDCXLVIII.*, to which was appended the *History of the University of Cambridge*, and the *History of Waltham Abbey.* The *Church History* called forth some strictures from Heylyn in his *Examen Historicum*, to which Fuller replied in a tract entitled *Appeal of Injured Innocence.* In 1658 Lord Berkely made him his chaplain, and presented him to the rectory of Cranford in Middlesex. It is also said that this nobleman took him over to the Hague, and introduced him to Charles II. there. Certain it is, that after the Restoration Fuller regained his lectureship at the Savoy, and was reinstated in his prebend of Salisbury. He was also appointed chaplain extraordinary to the king, made a doctor of divinity by *Mandamus*, and was within sight of a bishopric when a rather sudden death brought his earthly prospects to a close, 15th August 1661. He was buried in his church at Cranford, in the chancel of which a monument was erected to his memory.

The principal attribute of Fuller's genius is unquestionably wit; though, as Coleridge has well observed, "this very circumstance has defrauded him of his due praise for the practical wisdom—for the beauty and variety of the truths into which he shaped the stuff." His wit shows itself in the strangest forms, and whatever be the subject under discussion, it is sure to be presented in the wittiest guise. Sometimes it shows itself in a torrent of sarcasms so good-natured that the very person at whom they are levelled could not but join in the laugh against himself. At other times it exhausts itself in facetious stories, humorous illusions and illustrations and puns, more frequent and preposterous than those of Shakspeare himself. Even where a "lamentable accident" falls to be recorded, it is so mirthfully described that we feel ourselves more moved with laughter at the event than sympathy with the sufferers. A distressing catastrophe that befel a congregation of Catholics at Blackfriars is thus described—"The sermon began to incline to the middle, the day to the end thereof, when on a sudden the floor fell down whereon they were assembled. It gave no charitable warning groan beforehand, but cracked, broke, and fell all in an instant. Many were killed, more bruised, all frighted. Sad sight to behold the flesh and blood of different persons mingled together, and the brains of one on the head of another. One lacked a leg, another an arm, a third whole and entire, wanting nothing but breath, stifled in the ruins." In Fuller's treatment of serious or sacred subjects, however, whatever may be the appearance of profane or indecorous levity, there is never anything of the reality of it. It would, perhaps, have been safer, had he employed a less jocose phraseology when discussing grave subjects; but the whole tenor both of his life and writings proves him to have been a man of genuine religious sensibilities, not one of those who talk lightly on divine things because they feel lightly. But though one of the wittiest of men, Fuller was not merely witty. His fancy was only less characteristic and fertile than his wit, and was brilliant enough to have made the reputation of any inferior writer. But his indulgence of the dominant faculty of his mind has defrauded both his fancy and his wisdom of the admiration fairly due to them. Another faculty which Fuller possessed in rare perfection, that of memory, must not be here omitted. It is said that he could repeat five hundred strange words after once hearing them, and could make use of a sermon *verbatim* under the like circumstances. Another still more memorable instance of this power is recorded elsewhere. It is said that he undertook, after passing once from Temple Bar to the end of Cheapside, to tell at his return every sign as it stood in order on both sides of the way, and that he succeeded perfectly. Neither of these instances must necessarily be taken as strictly true (though far more wonderful ones are on record); but they both point to the fact that Fuller's memory was an uncommonly powerful one. As a writer, Fuller possesses many excellent qualities. Though a man of extensive erudition, he was absolutely free from all the forms of learned pedantry. His style is far more idiomatic than that of his illustrious contemporaries, Donne, Jeremy Taylor, Browne, and Burton; and he seems to have studiously avoided the Latinisms which form so large an element in their style. His sentences are simpler and shorter than theirs, and the majority of the words that compose them are of Saxon origin. This homely simplicity is to be accounted for by the fact that he used to collect the materials for his historical works, not by poring over dusty tomes in libraries, but by gossiping with the common people and listening for hours to their prolix accounts of local traditions and family legends. Though they do not display any great vigour of reasoning or wide command of principles, they are yet highly valuable as collections of admirably-told stories, reflecting quite as successfully as the most elaborate history the social spirit of that age. But though from their arrangements they are not immediately available as histories, they are a mine of wealth to more systematic and less eccentric writers. The moral spirit of Fuller's writings is admirable. His calmness and impartiality in discussing various delicate points of English ecclesiastical history contrast very favourably with the spirit of fierce partizanship displayed alike by most churchmen and dissenters of that age. It was in reference to this that Coleridge pronounced him "incomparably the most sensible, the least prejudiced great man of an age that boasted a galaxy of great men." He was a firm friend of the Established Church, and sometimes testified his attachment to it by flattering its chief dignitaries in terms unnecessarily fulsome. But it was with the deepest sorrow that he beheld the indignities practised against the Puritans, and wherever he could do so he did his best to screen and aid them.

In addition to the works already mentioned, Fuller wrote some others of less importance. These are—*Andronicus, or the Unfortunate Politician*, 12mo, Lond. 1646; *Good Thoughts in Worse Times*, 16mo, Lond. 1647; *Mixt Contemplations in Better Times*, 12mo, Lond. 1660; *The Speech of Birds, also of Flowers, partly moral and partly mystical*, 8vo, 1660. The most of Fuller's works have been several times reprinted.

FULLER'S EARTH, a species of clay much used in scouring woollen cloth and other stuffs. It occurs greenish, yellowish-gray, and bluish-gray, and sometimes it has a spotted appearance. It is dull, but assumes a fatty lustre when pressed with the fingers, is very soft, feels unctuous to the touch, and it melts into a brown spongy scoria before the blowpipe. In England it occurs in beds; the best is found in Buckinghamshire and Surrey. When good it has a greenish-white or greenish-gray colour, falls into powder when put into water, communicates a milky hue to water, and deposits very little sand when mixed with boiling water. It is used by fullers in taking grease out of cloth before the soap is applied. Its constituents are 53·0 silica, 10·0 alumina, 9·75 red oxide of iron, 1·25 magnesia, 0·5 lime, 24 water, with a slight trace of potash.

FULLING, the art of cleansing, scouring, and pressing cloths, stuffs, and stockings, to render them stronger, closer, and firmer. It is otherwise called *milling*. Pliny (vii. 56) relates that one Nicias, the son of Hermias, was the first inventor of the art of fulling; and it appears by an inscription, quoted by Sir G. Wheeler in his *Travels through Greece*, that this same Nicias was a governor in Greece in the time of the Romans.

The asperities upon the surface of wool render the spinning of it and the making it into cloth difficult operations. In order to spin wool, and afterwards convert it into cloth, its fibres must be covered with a coating of oil, which, filling the cavities, renders the asperities less sensible; in the same way that oil rubbed on the surface of a very fine file renders it less rough. When the piece of cloth is finished, it is carried to the fulling-mill, where it is beaten with heavy stampers in a trough full of water in which some fuller's earth has been mixed, for the purpose of cleansing it from the oil. The clay combines with the oil, which it separates from the cloth, and both are washed away together by the fresh water which is brought to it by the machine.

But the scouring of the cloth is not the only object in view in fulling it. The alternate pressure given by the stampers to the piece of cloth occasions (especially when the scouring is pretty far advanced), an effect analogous to that which is produced upon felt by the hands of the hatter. The fibres of wool which compose one of the threads, whether of the warp or the woof, assume a progressive movement, introduce themselves among those of the threads nearest to them, then into those which follow; and thus, by degrees, all the threads, both of the warp and the woof, become felted together. The cloth, after having by this means become shortened in all its dimensions, partakes both of the nature of cloth and of that of felt, and may be cut without being subject to ravel. Lastly, the cloth has acquired a greater degree of thickness, and forms a warmer clothing. Knit worsted also may thus be rendered less apt to run in case a stitch happen to drop.

The fulling of cloths and other stuffs is performed by a kind of water-mill, thence called a *fulling* or *scouring mill.* These mills, excepting in what relates to the mill-stones and hopper, are much the same with corn-mills; and there are even some which serve indifferently for both purposes. The principal parts of the fulling-mill are the wheel, with its trundle, which gives motion to the tree or spindle, whose teeth communicate it to the stampers, which are thereby raised and made to fall alternately, as its teeth catch or quit a kind of latch in the middle of each stamper. The stampers and troughs are commonly of wood; but sometimes the stampers are made of polished iron, and the cloth is exposed during the process to the action of steam; by which means the appearance of the cloth, when finished, is said to be greatly improved. These improvements formed the subject of a patent in 1825. In the course of the operation the fuller sometimes makes use of urine, sometimes of fuller's earth, and sometimes of soap. To prepare the stuffs to receive the first impressions of the stamper, they are usually laid in urine, then in fuller's earth and water, and lastly in soap dissolved in hot water. Soap alone would do very well, but it is expensive, and fuller's earth is scarcely inferior to it; but then it must be well cleared of all gritty particles, else it is apt to make holes in the stuff.

Method of fulling cloths and woollen stuffs with soap.—A coloured cloth of about 45 ells is to be laid in the usual manner in the trough of a fulling-mill, without first soaking it in water, as is commonly practised in many places. To full this trough of cloth, 15 pounds of soap are required, one-half of which is to be melted in two pails of river or spring water made as hot as the hand can well bear it. This solution is to be poured by degrees upon the cloth, as it is laid in the trough; and thus it is to be fulled for at least two hours, after which it is to be taken out and stretched. This done, the cloth is immediately returned into the same trough, without any new soap, and there fulled two hours more. It is then taken out and well wrung, to express all the grease and dirt. After the second fulling, the remainder of the soap is dissolved as in the former, and cast four different times on the cloth, which is taken out every two hours to stretch it, and undo the plaits and wrinkles it has acquired in the trough. When it is perceived to be sufficiently fulled, it is well scoured in hot water. With regard to white cloths, these full more easily and in less time than coloured ones, and thus require only a third part of the soap.

FULMINATING Compounds. Fulminates are of several kinds, being detonating compounds of the fulminic acid with various bases. Such are the fulminates of gold, mercury, silver, &c. The old fulminating powder is a mixture of nitre, sulphur, and potash. The fulminate of mercury is largely used as a priming to the percussion-caps for guns. See Chemistry, vi. p. 474.

FULMINATION (*fulmen*, thunder), in the Romish Church, a denunciation of censure or threats, as by papal authority.

FULTA, a large village of Hindustan, province of Bengal, on the east bank of the Hooghly, 20 miles S.S.W. in a straight line from Calcutta, but much more by the windings of the river. It has safe anchorage for ships, where they are protected from the swell of the sea, and where the anchors hold fast, the bottom being stiff clay. Lat. 22. 18., Long. 88. 10.

FULTON, Robert, a distinguished American engineer and mechanician, among the first who successfully applied steam to the propulsion of vessels, was born in 1765 at Little Britain in Pennsylvania. At a very early age he gave decided indications of mechanical genius. While still a mere youth he began life in Philadelphia as a portrait and landscape painter; and in his twenty-second year, with a view to improving himself in art, he visited England, where he remained for several years under the roof of his countryman West. He states that in 1793 he had conceived the design of propelling vessels by steam, but his numerous engagements prevented him from carrying it into effect at that time. His time was completely engrossed in devising a plane of double incline that should supersede the locks on canals, for which he obtained a patent from the British government in 1794. In the same year he obtained patents for flax-spinning and rope-twisting machines, and various other mechanical inventions, bearing chiefly upon the construction of canals, on which latter subject he published a treatise. In 1797 he removed to Paris, and remained for seven years in the house of Joel Barlow, the American minister at the court of Napoleon I., prosecuting his scientific studies. During that period he projected the first panorama ever exhibited in Paris, and made important experiments on submarine explosives. It was also at this time that he first succeeded, after repeated trials, in propelling a boat through the water by the aid of steam. In 1806 he returned to America, and repeated the experiment on a larger scale and with more decided success. In 1809 he took out his first patent, and seemed to be on the high way to wealth and prosperity, when his rights were disputed, and he became involved in legal proceedings, which embittered the remainder of his existence, and prevented him from reaping the rich harvest to which his industry and genius fairly entitled him. Fulton died Feb. 24, 1815. A minute account of his life and inventions is given in his biography by Cadwallader D. Colden. See STEAM NAVIGATION.

FULNEK, a town in the circle of Prerau, Austrian province of Moravia, 28 miles N.E. of Prerau. It has manufactures of linen and woollen goods, and about 3500 inhabitants.

FULNEK, the village in Yorkshire, 6 miles S.W. of Leeds, takes its name from this town, a colony of Moravians having settled there about 1723. Most of the inhabitants are still of that sect.

FUMIGATION, the employment of fumes or vapours for the purpose of purifying infected chambers, articles of apparel, &c. The most efficacious substance for this purpose is chlorine (see CHEMISTRY); next to it the vapour of nitric acid; and lastly that of muriatic acid. The fumes of heated vinegar, of sulphur, and the smoke of exploded gunpowder are of very little value as antiloimics.

FUNAMBULUS, among the Romans, a rope-dancer: called σχοινοβάτης, by the Greeks. The art of dancing on the tight-rope was carried to a wonderful degree of perfection among the Romans. In the *Ludi Florales* held under Galba, there were funambulatory *elephants*, as we are informed by Suetonius. Nero also gave similar entertainments in honour of his mother Agrippina: and Vopiscus relates the same of the time of Carinus and Numerianus.

FUNCHAL, the capital of Madeira. See MADEIRA.

FUNCTION, in *Analysis*, denotes an algebraical expression in any way compounded of a certain letter or quantity with other quantities or numbers; and the expression is said to be a function of that letter or quantity. Thus

$$a - 4x, \text{ or } ax + 3x^2, \text{ or } 2x - a\sqrt{a^2 - x^2}, \text{ or } x^c, \text{ or } e^x, \text{ is}$$

each of them a function of the quantity x.

FUND, in general, signifies a sum of money appropriated as the foundation of some commercial or other operation. Thus, that part of the national revenue which is set apart for the payment of the national debt is called the *sinking fund*. But, when we speak of *the funds*, we generally mean the large sums which have been lent to government and constitute the national debt; and for which the lenders, or their assignees, receive interest from revenues allotted for that purpose. The term *stock* is used in the same sense; and is also applied to the sums which form the capital of the Bank of England, the East India and the South Sea Companies; the proprietors of which are entitled to a share of the profits of the respective companies.

FUNDAMENTAL BASS. See MUSIC.

FUNDI, an ancient city of Latium. See FONDI.

FUNDING SYSTEM.

UNDER this head we propose, first, to give an account of the rise, progress, and modifications of the SINKING FUND, accompanied with some observations as to the probability of its accomplishing the object for which it was instituted; and, next, briefly to consider the best mode of providing for our annual expenditure both in war and peace,—an inquiry necessarily involving the policy of that SYSTEM OF FUNDING of which the sinking fund was long considered as one of the principal recommendations and props.

I. On the subject of the sinking fund, we shall have frequent occasion to refer to the statements of Professor Hamilton, in his very valuable publication entitled *An Inquiry concerning the Rise and Progress, the Redemption, and Present State of the National Debt of Great Britain.* "The first plan for the discharge of the national debt, formed on a regular system, and conducted with a considerable degree of firmness," says this able writer, "was that of the sinking fund, established in 1716. The author of this plan was the Earl of Stanhope; but as it was adopted under the administration of Sir Robert Walpole, it is commonly denominated from him. The taxes which had before been laid on for limited periods, being rendered perpetual, and distributed among the *South Sea*, *Aggregate*, and *General Funds*, and the produce of these funds being greater than the charges upon them, the surpluses, together with such further surpluses as might afterwards accrue, were united under the name of the *Sinking Fund*, being appropriated for the discharge of the national debt, and expressly ordained to be applicable to no other purpose whatever. The legal interest had been reduced from six to five per cent. about two years before; and as that reduction was unfavourable to the commercial state of the country, government was now able to obtain the same reduction on the interest of the public debt, and apply the savings in aid of the sinking fund. In 1727 a further reduction of the interest of the public debt, from five to four per cent. was obtained, by which nearly L.400,000 was added to the sinking fund. And, in the year 1749, the interest of part of the debt was again reduced to three and a half per cent. for seven years, and to three per cent. thereafter; and, in 1750, the interest of the remainder was reduced to three and a half per cent. for five years, and to three per cent. thereafter, by which a further saving of about L.600,000 was added to the sinking fund."

This sinking fund was for some time regularly applied to the discharge of debt. The sums applied from 1716 to 1728 amounted to L.6,648,000, being nearly equal to the additional debt contracted in that time. From 1728 to 1733, L.5,000,000 more were paid. The interest of seve-

[1] The article on the Funding System, by the late David Ricardo, Esq., has always been reputed so excellent that it has been considered advisable to retain it entire, and the supplement to it by his son will bring down the information on the subject to the present time.—ED.

ral loans, contracted between 1727 and 1732, was charged upon surplus duties, which, according to the original plan, ought to have been appropriated to the sinking fund.

"Soon after, the principle of preserving the sinking fund inviolable was abandoned. In 1733, L.500,000 was taken from that fund, and applied to the services of the year." "In 1734, L.1,200,000 was taken from the sinking fund for current services; and in 1735 it was anticipated and mortgaged." The produce of the sinking fund, at its commencement in 1717, was L.323,437. In 1776, it was at its highest amount, being then L.3,166,517; in 1780, it had sunk to L.2,403,017.

"The sinking fund would have risen higher, had it not been depressed, especially in the latter period, by various encroachments. It was charged with the interest of several loans, for which no provision was made; and, in 1772, it was charged with an annuity of L.100,000, granted in addition to the civil list. During the three wars which were waged while it subsisted, the whole of its produce was applied to the expense of the war; and even in time of peace, large sums were abstracted from it for current services. According to Dr Price, the amount of public debt paid off by the sinking fund, since its first alienation in 1733, was only three millions, paid off in 1736 and 1737; three millions in the peace between 1748 and 1756; two millions and a half in the peace between 1763 and 1775; in all, eight millions and a half.

"The additional debt discharged during these periods of peace was effected, not by the sinking fund, but from other sources.

"On the whole, this fund did little in time of peace, and nothing in time of war, to the discharge of the national debt. The purpose of its inviolable application was abandoned, and the hopes entertained of its powerful efficacy entirely disappointed. At this time, the nation had no other free revenue, except the land and malt-tax granted annually; and as the land-tax during peace was then granted at a low rate, their produce was inadequate to the expense of a peace establishment, on the most moderate scale. This gave occasion to encroachments on the sinking fund. Had the land-tax been always continued at 4s. in the pound, it would have gone far to keep the sinking fund, during peace, inviolate."

This fund terminated in 1786, when Mr Pitt's sinking fund was established.

To constitute this new fund, one million per annum was appropriated to it by parliament, the capital stock of the national debt then amounting to L.238,231,248.

This million was to be allowed to accumulate at compound interest, by the addition of the dividends on the stock which it purchased, till it amounted to four millions, from which time it was not further to increase. The four millions were then annually to be invested in the public funds as before, but the dividends arising from the stock purchased were no longer to be added to the sinking fund for the purpose of being invested in stock; they were to be applied to the diminution of taxes, or to any other object that parliament might direct.

A further addition to this fund was proposed by Mr Pitt, and readily adopted, in 1792, consisting of a grant of L.400,000 arising from the surplus of the revenue, and a further annual grant of L.200,000; but it was expressly stipulated that no relief from taxation should be given to the public, as far as this fund was concerned, till the original million, with its accumulations, amounted to four millions. The addition made to the fund, by the grant of L.400,000, and of L.200,000 per annum, together with the interest on the stock these sums might purchase, were not to be taken or considered as forming any part of the four millions. At the same time (in 1792), a sinking fund of a new character was constituted. It was enacted, that besides a provision for the interest of any loan which should thenceforward be contracted, taxes should also be imposed for a one per cent. sinking fund on the capital stock created by it, which should be exclusively employed in the liquidation of such particular loan; and that no relief should be afforded to the public from the taxes which constituted the one per cent. sinking fund, until a sum of capital stock, equal in amount to that created by the loan, had been purchased by it. That being accomplished, both the interest and sinking fund were to be applicable to the public service. It was calculated, that, under the most unfavourable circumstances, each loan would be redeemed in forty-five years from the period of contracting for it. If made in the three per cent., and the price of that stock should continue uniformly at 60, the redemption would be effected in twenty-nine years.

In the years 1798, 1799, and 1800, a deviation was made from Mr Pitt's plan of providing a sinking fund of one per cent. on the capital stock created by every loan; for the loans of those years had no sinking fund attached to them. The interest was charged on the war-taxes; and, in lieu of a one per cent. sinking fund, it was provided that the war-taxes should continue during peace, to be then employed in their redemption, till they were all redeemed.

In 1802, Lord Sidmouth, then Mr Addington, was chancellor of the exchequer. He being desirous of liberating the war-taxes from the charges with which they were encumbered, proposed to raise new annual permanent taxes for the interest of the loans of which we have just spoken, as well as for that which he was under the necessity of raising for the service of the year 1802; but he wished to avoid loading the public with additional taxes for a one per cent. sinking fund on the capitals created by those loans, and which capitals together amounted to L.86,796,375. To reconcile the stockholder to this arrangement, he proposed to rescind the provision which limited the fund of 1786 to four millions, and to consolidate the old and the new sinking funds, *i. e.* that which arose from the original million per annum, with the addition made to it of L.200,000 per annum subsequently granted, and that which arose from the one per cent. on the capital of every loan that had been contracted since 1792. These combined funds he proposed should from that time be applied to the redemption of the whole debt without distinction; that the dividends arising from the stock purchased by the commissioners for the reduction of the national debt should be applied in the same manner; and that this arrangement should not be interfered with till the redemption of the whole debt was effected.

In February 1803 the debt amounted to L.480,572,470, and the produce of the joint sinking fund to L.6,311,626. In 1786 the proportion of the sinking fund to the debt was as 1 to 238, in 1792 as 1 to 160, and in 1803 as 1 to 77.

This was the first deviation of importance from Mr Pitt's plan; and this alteration made by Lord Sidmouth was not, perhaps, on the whole, injurious to the stockholder. He lost, indeed, the immediate advantage of an additional sinking fund of L.867,963, the amount of one per cent. on the capitals created by the loans of 1798, 1799, 1800, and 1802; "but in lieu," says Mr Huskisson, "of this sinking fund, a reversionary sinking fund was created, to commence, indeed, in about twelve to fifteen years from that time, but to be of such efficacy when it should commence, and to be so greatly accelerated by subsequent additions in its progress, as, under the most unfavourable supposition, to be certain of reducing the whole of this debt within forty-five years. This reversionary sinking fund was to arise in the following manner; by continuing the *old* sinking fund at *compound* interest, *after* it should have reached its *maximum* of four millions; and by continuing also the *new* sinking fund or aggregate of the one per cents of the loans since 1792, after such one per cents should have liquidated the several loans in respect of which they are originally issued. There is nothing, therefore, in the act of 1802 which is a departure from the spirit of the act of 1792."[1]

The next alteration that was proposed to be made in the sinking fund was in 1807, by Lord Henry Petty, then chancellor of the exchequer. His plan was extremely complicated, and had for its object, that which ministers are too much disposed at all times to view with complacency, namely, to lessen the burden of taxation at the present, with the certainty of aggravating its pressure at a future day.

It was estimated by Lord Henry Petty, that the expenses of the country during war would exceed its permanent annual revenue by thirty-two millions. For twenty-one millions of this deficiency, provision was made by the war-taxes; the property-tax amounting to L.11,500,000, and the other war-taxes to L.9,500,000. The object then was to provide eleven millions per annum. If this sum had been raised by a loan in the three per cents, when their price was 60, provision must have been made by taxes for the interest and sinking fund, so that each year we should have required additional taxes to the amount of L.733,333. But government wished to raise the money without imposing these additional taxes, or by the imposition of as few as circumstances would permit. For this purpose they proposed to raise the money required, by loan, in the usual way, but to provide, out of the war-taxes, for the interest and redemption of the stock created. They proposed to increase the sinking fund of every such loan, by taking from the war-taxes ten per cent. on its amount for interest and sinking fund, so that if the interest and management absorbed only five per cent., the sinking fund would also amount to five per cent.; if the interest amounted to four per cent., the sinking fund would be six per cent. The sums proposed to be borrowed in this manner were twelve millions for the first three years, fourteen millions for the fourth, and sixteen millions for each succeeding year; making together, in fourteen years, 210 millions, for which, at the rate of ten per cent., the whole of the war-taxes would be mortgaged. It was calculated, that, by the operation of the sinking fund, each loan would be paid off in fourteen years from the time of contracting for it; and, therefore, the L.1,200,000 set apart for the interest and sinking fund of the first loan would be liberated and available for the loan of the fifteenth year. At the end of fifteen years a like sum would be set free, and so on each succeeding year; and thus loans might be continued, on this system, without any limitation of time.

But these successive sums could not be withdrawn from the war-taxes, for interest and sinking fund on loans, and be at the same time applied to expenditure; and, therefore, the deficiency of eleven millions, for which provision was to be made, would, from year to year, increase as the war-taxes became absorbed; and at the end of fourteen years, when the whole twenty-one millions of the war-taxes would be absorbed, instead of eleven millions, the deficiency would be thirty-two millions.

To provide for this growing deficiency, it was proposed to raise supplementary loans, increasing in amount from year to year; and for the interest and sinking fund on such loans, provision was to be made in the usual way by annual permanent taxes; on these loans the sinking fund was not to be more than one per cent.

By the plan proposed, in fifteen years from its commencement, on the supposition of the war continuing so long, the regular loan would have been twelve millions, and the supplementary loan twenty millions.

If the expenses of the war should *have exceeded* the estimate then made, provision for such excess was to *have been* made by other means.

The ministry who proposed this plan not continuing in office, it was acted upon only for one year. "In comparing the merit of different systems," says Dr Hamilton, "the only points necessary to be attended to are the amount of the loans contracted—the part of these loans redeemed—the interest incurred—and the sums raised by taxes. The arrangements of the loan under different branches, and the appropriation of particular funds for payment of their respective interests, are matters of official regulation; and the state of the public finance is neither the better nor the worse, whether they be conducted one way or other. A complicated system may perplex and mislead, but it can never ameliorate." Accordingly, Dr Hamilton has shown, that the whole amount of taxes that would have been paid in twenty years, for an annual loan of eleven millions on the old plan of a sinking fund of one per cent., would be 154 millions. On Lord Henry Petty's plan, these taxes would, in the same time, have been ninety-three millions,—a difference in favour of Lord Henry Petty's plan, of fifty-one millions; but to obtain this exemption we should have been encumbered with an additional debt of L.119,489,788 of money capital, which, if raised in a three per cent. stock at 60, would be equal to a nominal capital of L.199,149,646.

The sinking fund was established with a view to diminish the national debt during peace, and to prevent its rapid increase during war. The only wise and good object of war-taxes is also to prevent the accumulation of debt. A sinking fund and war-taxes are only useful while they are strictly applied to the objects for which they are raised; they become instruments of mischief and delusion when they are made use of for the purpose of providing the interest on a new debt.

In 1809, Mr Perceval, who was then chancellor of the exchequer, mortgaged L.1,040,000 of the war-taxes for the interest and sinking fund of the stock he funded in that year.

By taking more than a million from the war-taxes, not for the annual expenditure, but for the interest of a loan, Mr Perceval rendered it necessary to add one million to the loan of the next and all following years; so that the real effect of this measure differed in no respect from one which should have taken the same sum annually from the sinking fund.

In 1813, the next and most important alteration was made in the sinking fund. Mr Vansittart was then chancellor of the exchequer. It has been already observed, that the national debt amounted to L.238,231,248 in 1786, when Mr Pitt established his sinking fund of one million. By the act of 1786, as soon as the sum of one million amounted, by the aid of the dividends on the stock which was to be purchased by it, to four millions, its accumulation was to cease, and the dividends on the stock purchased were to be available for the public service. If the three per cents were at sixty when this million had accumulated to four millions, the public would have had a disposable fund of L.20,000 per annum; if at eighty, of L.15,000 per annum; and no other relief was to be given to the public till the four millions had purchased the whole sum of 238 millions, the then amount of the debt. In 1792, Mr Pitt added L.200,000 per annum to the sinking fund, and accompanied it by the following observations: "When the sum of four millions was originally fixed as the limit for the sinking fund, it was not in contemplation to issue more annually from the surplus revenue than one million; consequently, the fund would not rise to four millions till a proportion of debt was paid off, the interest of which, together with the annuities which might fall in in the interval, should amount to three millions. But as, on the present supposition, additional sums beyond the original million are to be annually issued from the revenue, and applied to the aid of the sinking fund, the consequence would be, that if that fund, with these additions carried to it, were still to be limited to four millions, it would reach that amount, and cease to accumulate, before as great a portion of the debt is reduced as was originally in contemplation." "In order to avoid this consequence, which would, as far as it went, be a relaxation in our system, I should propose, that whatever may be the additional annual sums applied to the reduction of debt, the fund should not cease to accumulate till the interest of the capital discharged, and the amount of the expired annuities, should, together with the annual million only, and exclusive of any additional sums, amount to four millions."[1]

---

[1] Mr Huskisson's *Speech on the State of the Finance and Sinking Fund*, 25th March 1813.

It will be recollected, that in 1792 a provision was made for attaching a sinking fund of one per cent. to each loan separately, which was to be exclusively employed in the discharge of the debt contracted by that loan; but no part of these one per cents were to be employed in the reduction of the original debt of L.238,000,000. The act of 1802 consolidated all these sinking funds, and the public were not to be exempted from the payment of the sinking fund itself, nor of the dividends on the stock to be purchased by the commissioners, till the whole debt existing in 1802 was paid off. Mr Vansittart proposed to repeal the act of 1802, and to restore the spirit of Mr Pitt's act of 1792. He acknowledged that it would be a breach of faith to the national creditor, if the fair construction of that act, the act of 1792, were not adhered to. It was, in Mr Vansittart's opinion, no breach of faith to do away the conditions of the act of 1802. Supposing, however, that the act of 1802 had been really more favourable to the stockholder than that of 1792, it is not easy to comprehend by what arguments it can be proved not to be a breach of faith to repeal the one and enact the other. Were not all the loans from 1802 to 1813 negotiated on the faith of that act? Were not all bargains made between the buyer and seller of stock made on the same understanding? Government had no more right to repeal the act of 1802, and substitute another less favourable to the stockholder, and acknowledged to be so by the minister himself, than it would have had to get rid of the sinking fund altogether. But what we are at present to inquire into is, whether Mr Vansittart did as he professed to do? Did he restore the stockholder to all the advantages of the act of 1792? In the first place, it was declared by the new act, that as the sinking fund consolidated in 1802, had redeemed L.238,350,143. 18s. 1d. exceeding the amount of the debt in 1786 by L.118,895. 12s. 10½d., a sum of capital stock equal to the total capital of the public debt existing on the 5th January 1786, viz. L.238,231,248. 5s. 2¾d. had been satisfied and discharged; "and that in like manner an amount of public debt equal to the capital and charge of every loan contracted since the said 5th January 1786, shall successively, and in its proper order, be deemed and declared to be wholly satisfied and discharged, when and as soon as a further amount of capital stock, not less than the capital of such loan, and producing an interest equal to the dividends thereupon, shall be so redeemed or transferred."

It was also resolved, "that after such declaration as aforesaid, the capital stock purchased by the commissioners for the reduction of the national debt shall from time to time be cancelled; at such times, and in such proportions, as shall be directed by any act of parliament to be passed for such purpose, in order to make provision for the charge of any loan or loans thereafter to be contracted."

It was further resolved, that in order to carry into effect the provisions of the acts of the 32d and 42d of the king, for redeeming every part of the national debt within the period of forty-five years from the time of its creation, it is expedient that in future, whenever the amount of the sum to be raised by loan, or by any other addition to the public funded debt, shall in any year exceed the sum estimated to be applicable in the same year to the reduction of the public debt, an annual sum equal to one half of the interest of the excess of the said loan, or other addition, beyond the sum so estimated to be applicable, shall be set apart out of the monies composing the consolidated fund of Great Britain, and shall be issued at the receipt of the exchequer to the governor and company of the Bank of England, to be by them placed to the account of the commissioners for the reduction of the national debt;[2] and upon the remainder of such loan or other addition, the annual sum of one per cent. on the capital thereof, according to the provisions of the said act.

A provision was also made, for the first time, for one per cent. sinking fund on the unfunded debt then existing, or which might thereafter be contracted.

In 1802, it has been already observed, it was deemed expedient that no provision should be made for a sinking fund of one per cent. on a capital of L.86,796,300; and as it was considered by the proposer of the new regulation in 1813, that he was reverting to the principle of Mr Pitt's act of 1792, he provided that L.867,963 should be added to the sinking fund for the one per cent. on the capital stock created, and which was omitted to be provided for in 1802.[3]

This was the substance of Mr Vansittart's new plan, and which, he contended, was not injurious to the stockholder, as it strictly conformed to the spirit of Mr Pitt's act of 1792.

1*st*, By Mr Pitt's act, no relief could be afforded to the public from the burdens of taxation, till the stock redeemed by the original sinking fund of one million amounted to such a sum as that the dividends on the capital stock redeemed should amount to three millions, making the whole sinking fund four millions; from thenceforth the four millions were to discharge debt as before, but the interest of

---

[1] Mr Pitt's Speech, 17th February 1792.

[2] The effect of this clause was to give a sinking fund of one and a half instead of one per cent. on such excess of loan above the sinking fund if the loan were raised in a three per cent. stock, and of two and a half per cent. if raised in a five per cent. stock.

[3]

Mr Vansittart's plan has added to the sinking fund one per cent. on a capital of L.86,796,300	L.867,936
On fifty-six millions of exchequer bills outstanding 5th January 1818, one per cent	560,000
By attaching a sinking fund of one half the interest, instead of one per cent. on a part of the capital created by loans, *he has added to the sinking fund*	793,343
Total added	L.2,221,311
From stock cancelled and available for public service	7,632,969
Total deduction from sinking fund on 5th January 1819	L.5,411,658

On the 3d of February 1819 the commissioners certified that there had been transferred to them L.378,519,969. 5s. 3¾d. capital stock, the interest on which was L.11,448,564. 10s. 6¼d., and that the debt created prior to and by the 37th Geo. III. amounted to L.348,684,197. 1s. 5¾d., with a yearly interest of L 11,446,736. 3s. 4¾d.; and consequently the excess redeemed was L.29,835,772. 3s. 9¼d., with a yearly interest of L.1828. 7s. 1¼d.

debt so discharged was to be available for the public service, and the public was not to be relieved from the charge on the remainder of the debt of 238 millions till the four millions at simple interest, and the further sinking fund which might arise from the falling in of terminable annuities, together with the additional sum of L.200,000 per annum, voted in 1792, with their accumulations, had redeemed the capital of 238 millions. The sinking fund arising from the one per cent. on each loan was directed, by the act of 1792, to be applied to each separate loan for which it was raised. Mr Vansittart thought himself justified, and free from any breach of faith to the stockholder, in taking for the public service, not the interest of four millions, which is all that Mr Pitt's bill would allow him to take, but the interest on 238 millions; and on what plea? because the whole consolidated sinking funds, comprising the one per cent. on every loan raised since 1793, had purchased 238 millions of stock. On Mr Pitt's plan he might have taken L.20,000 per annum from the sinking fund; on his own construction of that act, he took from it more than seven millions per annum.

2dly, Mr Vansittart acknowledged that the stockholder, in 1802, was deprived of the advantage of one per cent. sinking fund on a capital of L.86,796,300; and therefore, to be very just, he gives in 1813 one per cent. on that capital; but should he not have added the accumulation which would have been made in the eleven years from 1802 to 1813, on L.867,963, at compound interest, and which would have given a further addition to the sinking fund of more than L.360,000 per annum?

3dly, On Mr Pitt's plan, every loan was to be redeemed by its sinking fund, under the most unfavourable circumstances, in forty-five years. If the loan was raised in a three per cent. fund at sixty, and the stock was uniformly to continue at that price, a one per cent. sinking fund would redeem the loan to which it was attached in twenty-nine years; but then no relief would be given to the public from taxation till the end of twenty-nine years; and if there had been loans of ten millions every year for that period, when the first loan was paid off, the second would require only one year for its final liquidation; the third two years, and so on. On Mr Vansittart's plan, under the same circumstances, the sinking fund of each and every loan was to be applied, in the first instance, to the redemption of the first loan; and when that was redeemed and cancelled, the whole of the sinking funds were to be applied to the payment of the second, and so on successively. The first loan of ten millions would be cancelled in less than thirteen years, the second in less than six years after the first, the third in a less time, and so on. At the end of the thirteenth year, the public would be relieved from the interest on the first loan, or, which is the same thing, from the necessity of finding fresh taxes for a new loan at the end of thirteen years, for two new loans at the end of nineteen years; but what would be the state of its debt at either of these periods, or at the end of twenty-nine years? Could this advantage be obtained without a corresponding disadvantage? No; the excess of debt on Mr Vansittart's plan would be exactly equal to these various sums, thus prematurely released by cancelled stock, accumulated at compound interest. How could it be otherwise? Is it possible that we could obtain a present relief from the charge of debt without either directly or indirectly borrowing the fund necessary to provide that relief at compound interest? " By this means," says Mr Vansittart, " the loan first contracted would be discharged at an earlier period, and the funds charged with the payment of its interest would become applicable to the public service. Thus, in the event of a long war, a considerable resource might accrue during the course of the war itself, as every successive loan would contribute to accelerate the redemption of those previously existing; and the total amount of charge to be borne by the public, in respect of the public debt, would be reduced to a narrower compass than in the other mode, in which a greater number of loans would be co-existing. At the same time the ultimate discharge of the whole debt would be rather accelerated than retarded."—" It is now only necessary to declare that an amount of stock equal to the whole of the debt existing in 1786 has been redeemed; and that, in like manner, whenever an amount of stock equal to the capital and charge of any loan raised since 1792 shall be redeemed, in its proper order of succession, such loan shall be deemed and taken to be redeemed and satisfied. Every part of the system will then fall at once into its proper place; and we shall proceed with the future redemption with all the advantages which would have been derived from the original adoption of the mode of successive instead of simultaneous redemption. Instead of waiting till the purchase of the whole of the debt consolidated in 1802 shall be completed, that part of it which existed previously to 1792 will be considered as already redeemed, and the subsequent loans will follow in succession, whenever equal portions of stock shall have been purchased. It is satisfactory to observe, that by a gradual and equal progress, we shall have the power of effecting the complete repayment of the debt more speedily than by the present course." Is it possible that Mr Vansittart could so deceive himself as to believe that, by taking five millions from the sinking fund, which would not have been taken by the provisions of the act of 1802, which would not have been taken by the act of 1792, and other sums successively, in shorter times than could have been effected by the provisions of those two acts, he would be enabled to complete the repayment of the debt more speedily? Is it possible that he could believe that, by diminishing the sinking fund, that is, the amount of revenue as compared with expenditure, he would effect the payment of our debt more speedily? It is impossible to believe this. How then are his words to be accounted for? In one way he might have a meaning. It might be this,—I know we shall be more in debt in ten, twenty, and thirty years, on my plan, than we should have been on that of Lord Sidmouth or on that of Mr Pitt; but we shall have effected a greater payment in that time of *the stock now existing*, as the sinking funds attached to future loans will be employed in paying our present debt. On Mr Pitt's plan, those sinking funds would be used for the payment of the new debt to be created; that is to say, of the loans to which they are respectively attached. We shall be more in debt at every subsequent period, it is true; but as our debt may be divided into old stock and new stock, I am correct when I say that we shall have the power of completing the repayment of the debt, meaning by the debt the stock now existing, sooner than by the present course.

This plan of Mr Vansittart was opposed with great ability, both by Mr Huskisson and Mr Tierney. The former gentleman said, " The very foundation of the assumption that the old debt has been paid off, is laid in the circumstance of our having incurred a new debt of a much larger amount; and even allowing that assumption, Mr Vansittart would not have been able to erect his present scheme upon it, if the credit of the country had not been, for the last twenty years, materially impaired by the pressure of that new debt. On the one hand, had the sinking fund been operating at three per cent. during that period, he would not have touched it, even under his own construction of the act of 1792. On the other hand, had the price of the stocks been still lower than it has been, he would have taken from that sinking fund still more largely than he is now, according to his own rule, enabled to take. This then is the new doctrine of the sinking fund;—that, having been originally established ' to prevent the inconvenient and dangerous accumulation of debt hereafter' (to borrow the very words of the act), and for the support and improvement of public credit, it is in the accumulation of new debt that Mr Vansittart found at once the means and the pretence for invading that sinking fund; and the degree of depression of public credit was, with him, the measure of the extent to which that invasion might be carried. And this is the system of which it is gravely predicated, that it is no departure from the letter, and no violation of the spirit, of the act of 1792; and of which we are desired seriously to believe, that it is only the following up and improving upon the original measure of Mr Pitt!—of which measure the clear and governing intention was, that every future loan should, from *the moment of its creation*, carry with it the seeds of its destruction; and that the course of its reimbursement should *that moment* be placed beyond the discretion and control of parliament." (Mr Huskisson's *Speech*, 25th March 1813.)

This is the last alteration that has taken place in the *machinery* of the sinking fund. Inroads more fatal than this which we have just recorded have been made on the fund itself; but they have been made silently and indirectly, while the machinery has been left unaltered.

It has been shown by Dr Hamilton, that no fund can be efficient for the reduction of debt but such as arises from an excess of revenue above expenditure.

Suppose a country at peace, and its expenditure, including the interest of its debt, to be forty millions, its revenue to be forty-one millions, it would possess one million of sinking fund. This million would accumulate at compound interest; for stock would be purchased with it in the market, and placed in the names of the commissioners for paying off the debt. These commissioners would be entitled to the dividends before received by private stockholders, which would be added to the capital of the sinking fund. The fund thus increased would make additional purchases the following year, and would be entitled to a larger amount of dividends, and thus would go on accumulating, till in time the whole debt would be discharged.

Suppose such a country to increase its expenditure one million, without adding to its taxes, and to keep up the machinery of the sinking fund; it is evident that it would make no progress in the reduction of its debt; for though it would accumulate a fund in the same manner as before in the hands of the commissioners, it would, by means of adding to its funded or unfunded debt, and by constantly borrowing, in the same way, the sum necessary to pay the interest on such loans, accumulate its million of debt annually at compound interest, in the same manner as it accumulated its million annually of sinking fund.

But suppose that it continued its operations of investing the sinking fund in the purchase of stock, and made a loan for the million which it was deficient in its expenditure, and that, in order to defray the interest and sinking fund of such loan, it imposed new taxes on the people to the amount of L.60,000, the real and efficient sinking fund would, in that case, be L.60,000 per annum, and no more; for there would be L.1,060,000, and no more, to invest in the purchase of stock, while one million was raised by the sale of stock, or, in other words, the revenue would exceed the expenditure by L.60,000.

Suppose a war to take place, and the expenditure to be increased to sixty millions, while its revenue continued, as before, forty-one millions, still keeping on the operation of the commissioners with respect to the investment of one million. If it were to raise war-taxes for the payment of the twenty millions additional expense, the million of sinking fund would operate to the reduction of the national debt at compound interest as it did before. If it raised twenty millions by loan in the stocks or in exchequer bills, and did not provide for the interest by new taxes, but obtained it by an addition to the loan of the following year, it would be accumulating a debt of twenty millions at compound interest; and while the war lasted, and the same expenditure continued, it would not only be accumulating a debt of twenty millions at compound interest, but a debt of twenty millions per annum; and consequently the real increase of its debt, after allowing for the operation of the million of sinking fund, would be at the rate of nineteen millions per annum at compound interest. But if it provided by new taxes five per cent. interest for this annual loan of twenty millions, it would on the one hand simply increase the debt twenty millions per annum; on the other it would diminish it by one million per annum, with its compound interest. If we suppose that, in addition to the five per cent. interest, it raised also by annual taxes L.200,000 per annum as a sinking fund for each loan of twenty millions, it would, the first year of the war, add L.200,000 to the sinking fund, the second year L.400,000, the third year L.600,000, and so on, L.200,000 for every loan of twenty millions. Every year it would add, by means of the additional taxes, to its annual revenue, without increasing its expenditure. Every year, too, that part of this revenue which was devoted to the purpose of purchasing debt, would increase by the amount of the dividends on the stock purchased; and thus would its revenue still further increase, till at last the revenue would overtake the expenditure, and then once again it would have an efficient sinking fund for the reduction of debt.

It is evident that the result of these operations would be the same, the rate of interest being supposed to be always at five per cent. or any other rate, if, during the excess of expenditure above revenue, the operation of the commissioners in the purchase of stock were to cease. The real increase of the national debt must depend upon the excess of expenditure above revenue, and that would be noways altered by a different arrangement. Suppose that, instead of raising twenty millions the first year, and paying off one million, only nineteen millions had been raised by loan, and the same taxes had been raised, namely, L.1,200,000. As five per cent. would be paid on nineteen millions only, instead of on twenty millions, or L.950,000 for interest instead of one million, there would remain, in addition to the original million, L.250,000 towards the loan of the following year, consequently the loan of the second year would be only for L.18,750,000; but as L.1,200,000 would be again raised by additional taxes, or L.2,400,000 in the whole the second year, besides the original million, there would be a surplus, after paying the interest of both loans, of L.1,512,500, and therefore the loan of the third year would be for L.18,487,500. The progress during five years is shown in the following table:—

	Loan each Year.	Amount of Loans.	Amount of Interest.	Amount of Taxes.	Surplus.
1st year.........	L.19,000,000	L.19,000,000	L.950,000	L.2,200,000	L.1,250,000
2d year..........	18,750,000	37,750,000	1,887,500	3,400,000	1,512,500
3d year..........	18,487,500	56,237,500	2,811,875	4,600,000	1,788,125
4th year.........	18,211,875	74,449,375	3,722,469	5,800,000	2,077,531
5th year.........	17,922,469	92,371,844	4,618,592	7,000,000	2,381,408

If, instead of thus diminishing the loan each year, the same amount of taxes precisely had been raised, and the sinking fund had been applied in the usual manner, the amount of debt would have been exactly the same at any one of these periods. In the third column of the above table it will be seen, that in the fifth year the debt had increased to L.92,371,844. On the supposition that L.200,000 per annum had each year been added to the sinking fund, and invested in stock by the commissioners, the amount of unredeemed debt would have been the same sum of L.92,371,844, as will be seen by the last column of the following table :—

	Loan each Year.	Amount of Loans.	Debt redeemed each Year.	Amount Debt Redeemed.	Interest on Debt Redeemed.	Debt remaining Unredeemed.
1st year.........	L.20,000,000	L.20,000,000	L.1,000,000	L.1,000,000	L.50,000	L.19,000,000
2d year..........	20,000,000	40,000,000	1,250,000	2,250,000	112,500	37,750,000
3d year..........	20,000,000	60,000,000	1,512,500	3,762,500	188,125	56,237,500
4th year.........	20,000,000	80,000,000	1,788,125	5,550,625	277,531	74,449,375
5th year.........	20,000,000	100,000,000	2,077,531	7,628,156	381,408	92,371,844

A full consideration of this subject in all its details has led Dr Hamilton to the conclusion that this first mode of raising the supplies during war, viz. by diminishing the amount of the annual loans, and stopping the purchases of the commissioners in the market, would be more economical, and that it ought therefore to be adopted. In the first place, all the expenses of agency would be saved; in the second, the premium usually obtained by the contractor for the loan would be saved on that part of it which is repurchased by the commissioners in the open market. It is true that the stocks may fall as well as rise between the time of contracting for the loan and the time of the purchases made by the commissioners; and therefore, in some cases, the public may gain by the present arrangement; but as these chances are equal, and a certain advantage is given to the loan contractor to induce him to advance his money, independently of all contingency of future price, the public now give this advantage on the larger sum instead of on the smaller. On an average of years, this cannot fail to amount to a very considerable sum. But both these objections would be obviated, if the clause in the original sinking fund bill, authorizing the commissioners to subscribe to any loan for the public service, to the amount of the annual fund which they have to invest, were uniformly complied with. This is the mode which was for several years strongly urged by Mr Grenfell; and it is far preferable to that which Dr Hamilton recommends. Dr Hamilton and Mr Grenfell both agree, that in time of war, when the expenditure exceeds the revenue, and when therefore we are annually increasing our debt, it is a useless operation to buy a comparatively small quantity of stock in the market, while we are at the same time under the necessity of making large sales: but Dr Hamilton would not keep the sinking fund as a separate fund; Mr Grenfell would, and would have it increased with our debt by some known and fixed rules. We agree with Mr Grenfell. If a loan of twenty millions is to be raised annually, while there is in the hands of the commissioners ten millions which they annually receive, the obvious and simple operation should be really to raise only ten millions by loan; but there is a convenience in calling it twenty millions, and allowing the commissioners to subscribe ten millions. All the objections of Dr Hamilton are by these means removed; there will be no expense for agency; there will be no loss on account of any difference of price at which the public sell and buy. By calling the loan twenty millions, the public will be induced more easily to bear the taxes which are necessary for the interest and sinking fund of twenty millions. Call the loan only ten millions, abolish during the war the very name of the sinking fund in all your public accounts, and it would be difficult to show to the people the expediency of providing L.1,200,000 per annum by additional taxation for the interest of a loan of ten millions. The sinking fund is therefore useful as an engine of taxation; and if the country could depend on ministers that it would be faithfully devoted to the purposes for which it was established, namely, to afford at the termination of war a clear additional surplus revenue beyond expenditure, in proportion to the addition made to the debt, it would be wise and expedient to keep it as a separate fund, subject to fixed rules and regulations.

We shall presently inquire whether there can be any such dependence; and therefore whether the sinking fund is not an instrument of mischief and delusion, and really tending rather to increase our debt and burdens than to diminish them.

It is objected both to Dr Hamilton's and Mr Grenfell's projects, that the disadvantages which they mention are trifling in degree, and are more than compensated by the steadiness which is given to the market by the daily purchases of the commissioners; that the money which those purchases throw into the market is a resource on which bankers and others, who may suddenly want money, with certainty rely.

Those who make this objection forget, that if, by the adoption of this plan, a daily purchaser is withdrawn from the market, so also is a daily seller. The minister gives now to one party ten millions of money to invest in stock, and to another party as much stock as ten millions costs to sell; and as the instalments on the loan are paid monthly, it may fairly be said that the supply is as regular as the demand. It cannot be doubted too, that a loan of twenty millions is negotiated on worse terms than one of ten. It is true that no more stock will remain in the market at the end of the year, whether the one or the other sum be raised by loan; but for a time the contractor must make a large purchase, and he must wait before he can make his sale of ten millions to the commissioners. He is induced then to sell much more largely before the contract, which cannot fail to affect the market price; and it must be recollected, that it is the market price on the day of bidding for the loan which governs the terms on which the loan is negotiated. It is looked to both by the minister who sells and the contractor who purchases. The experiment on Mr Grenfell's suggestion was tried for the first time in 1819; the sum required by government was twenty-four millions, to which the commissioners subscribed twelve millions. In lieu of a loan of twenty-four millions from the contractor, there was one only of twelve millions; and as soon as this arrangement was known, previous to the contract, the stocks rose to four or five per cent., and influenced the terms of the loan in that degree. The reason was, that a preparation had been made for twenty-four or thirty millions loan; and as soon as it was known that it would be for twelve millions only, a part of the stock sold was repurchased. Another advantage attending the smaller loan is, that eight hundred per million, which is paid to the bank for management of the loan, is saved on the sum subscribed by the commissioners.

Dr Hamilton, in another part of his work, observes, " If the sinking fund could be conducted without loss to the public, or even if it were attended with a moderate loss, it would not be wise to propose an alteration of a system which has gained the confidence of the public, and which points out a rule of taxation that has the advantage at least of being steady. If that rule be laid aside, our measures of taxation might become entirely loose."

"The means, and the only means, of restraining the progress of national debt, are saving of expenditure and increase of revenue. Neither of these has a necessary connection with a sinking fund. But if they have an eventual connection, and if the nation, impressed with a conviction of the importance of a system established by a popular minister, has, in order to adhere to it, adopted measures, either of frugality in expenditure, or exertion in raising taxes, which it would not otherwise have done, the sinking fund ought not to be considered as inefficient, and its effects may be of great importance."

It will not, we think, admit of a doubt, that if Mr Pitt's sinking fund, as established in 1792, had been always fairly acted upon,—if, for every loan, in addition to the war-taxes, the interest, and a one per cent. sinking fund, had been invariably supplied by annual taxes,—we should have made rapid progress in the extinction of debt. The alteration in principle which was made in the sinking fund by the act of 1802, was, in our opinion, a judicious one: it provided that no part of the sinking fund, neither that which arose from the original million, with its addition of L.200,000 per annum, nor that which arose from the one per cent. raised for the loans since 1792, should be applicable to the public service, till the whole of the debt then existing was redeemed. We should have been disposed to extend this principle further, and to make a provision, that no part of the sinking fund should be applicable to the public service until the whole of the debt then existing, *and subsequently to be created*, should be redeemed. We do not think that there is much weight in the objection to this clause which was made to it by Lord Henry Petty in 1807, and referred to and more strongly urged by Mr Vansittart in 1813. The noble Lord said, "I need hardly press upon the consideration of the committee, all the evils likely to result from allowing the sinking fund to accumulate without any limit; for the nation would be exposed by that accumulation to the mischief of having a large portion of capital taken at once out of the market, without any adequate means of applying it, which would of course be deprived of its value.

"This evil must appear so serious to any man who contemplates its character, that I have no doubt it will be felt, however paradoxical it may seem, that the redemption of the whole national debt at once would be productive of something like national bankruptcy; for the capital would be equivalent almost to nothing, while the interest he had before derived from it would be altogether extinguished. The other evils which would arise from, and which must serve to demonstrate the mischievous consequence of, a prompt discharge of the national debt, I will show presently. Different arrangements were adopted in the further provisions made on the subject of the sinking fund in 1792 and in 1802. By the first the sinking fund of one per cent., which was thenceforward to be provided for every new loan, was made to accumulate at compound interest until the whole of the debt created by such new loan should be extinguished. And, by the second arrangement, all the various sinking funds existing in 1802 were consolidated, and the whole were appropriated to accumulate at compound interest until the discharge of the whole of the debt also existing in 1802. But the debt created since 1802, amounting to about one hundred millions of nominal capital, is still left subject to the act of 1792, which provides for each separate loan a sinking fund of only one per cent. on the nominal capital. The plan of 1802, engrafted on the former acts of 1786 and 1792, provided for the still more speedy extinction of the debt to which it applied. But it would postpone all relief from the public burdens to a very distant period (computed in 1802 to be from 1834 to 1844); and it would throw such large and disproportionate sums into the money market in the latter years of its operation, as might produce a very dangerous depreciation of the value of money. Many inconveniences might also arise from the sudden stop which would be put to the application of those sums when the whole debt should have been redeemed, and from the no less sudden change in the price of all commodities, which must follow from taking off at one and the same moment taxes to an extent probably then much exceeding thirty millions. The fate of merchants, manufacturers, mechanics, and every description of dealers, in such an event, must be contemplated by every thinking man with alarm; and this applies to my observation respecting a national bankruptcy; for, should the national debt be discharged, and such a weight of taxation taken off at once, all the goods remaining on hand would be, comparatively speaking, of no value to the holders, because, having been purchased or manufactured while such taxation prevailed, they must be undersold by all those who might manufacture the same kind of goods after such taxation had ceased. These objections were foreseen, and to a certain degree acknowledged, at the time when the act of 1802 was passed; and it was then answered, that whenever the danger approached, it might be obviated by subsequent arrangements." A great many of these objections appear to us to be chimerical; but, if well founded, we agree with the latter part of the extract, "whenever the danger approached, it might be obviated by subsequent arrangements." It was not necessary to legislate in 1807 or in 1813, for a danger which could not happen till between 1834 and 1844. It was not necessary to provide against the evils which would arise from a plethora of wealth at a remote period, when our real difficulty was how to supply our immediate and pressing wants.

What are the evils apprehended from the extravagant growth of the sinking fund towards the latter years of its existence? Not that taxation will be increased, because the growth of the sinking fund is occasioned by dividends on stock purchased; but, first, that capital will be returned too suddenly into the hands of the stockholder, without his having any means of deriving a revenue from it; and, secondly, that the remission of taxes, to the amount probably of thirty millions, will have a great effect on the prices of particular commodities, and will be very pernicious to the interest of those who may deal in or manufacture such commodities.

It is obvious that the commissioners have no capital. They receive quarterly or daily certain sums, arising from the taxes, which they employ in the redemption of debt. One portion of the people pay what another portion receive. If the payers employed the sums paid as capital, that is to say, in the production of raw produce, or manufactured commodities, and the receivers, when they received it, employed it in the same manner, there would be little variation in the annual produce. A part of that produce might be produced by A instead of by B: not that even this is a necessary consequence; for A, when he received the money for his debt, might lend it to B, and might receive from him a portion of the produce for interest, in which case B would continue to employ the capital as before. On the supposition, then, that the sinking fund is furnished by capital and not by revenue, no injury would result to the community, however large that fund might be; there might or might not be a transfer of employments, but the annual produce, the real wealth of the country, would undergo no deterioration, and the actual amount of capital employed would neither be increased nor diminished. But if the payers of taxes, for the interest and sinking fund of the national debt, paid them from revenue, then they would retain the same capital as before in active employment; and as this revenue, when received by the stockholder, would be by him employed as capital, there would be, in consequence of this operation, a great increase of capital; every year an additional portion of revenue would be turned into capital, which could be employed only in furnishing new commodities to the market. Now, the doubts of those who speak of the mischievous effects of the great accumulation of the sinking fund, proceed from an opinion they entertain that a country may possess more capital than it can beneficially employ, and that there may be such a glut of commodities that it would be impossible to dispose of them on such terms as to secure to the producers any profits on their capitals. The error of this reasoning has been made manifest by M. Say, in his able work *Economie Politique*, and afterwards by Mr Mill, in his excellent reply to Mr Spence, the advocate of the doctrine of the Economistes. They show that demand is only limited by production; whoever can produce has a right to consume, and he will exercise his privilege to the greatest extent. They do not deny that the demand for particular commodities is limited, and therefore they say there may be a glut of such commodities; but, in a great and civilized country, wants, either for objects of necessity or of luxury, are unlimited, and the employment of capital is of equal extent with our ability of supplying food and necessaries for the increasing population, which a continually augmenting capital would employ. With every increased difficulty of producing additional supplies of raw produce from the land, corn, and the other necessaries of the labourer, would rise. Hence wages would rise. A real rise of wages is necessarily followed by a real fall of profits; and therefore, when the land of a country is brought to the highest state of cultivation, when more labour employed upon it will not yield in return more food than what is necessary to support the labourer so employed, that country is come to the limit of its increase both of capital and population.

The richest country in Europe is yet far distant from that degree of improvement; but if any had arrived at it, by the aid of foreign commerce, even such a country could go on for an indefinite time increasing in wealth and population; for the only obstacle to this increase would be the scarcity, and consequent high value, of food and other raw produce. Let these be supplied from abroad in exchange for manufactured goods, and it is difficult to say where the limit is at which you would cease to accumulate wealth, and to derive profit from its employment. This is a question of the utmost importance in political economy. We hope that the little we have said on the subject will be sufficient to induce those who wish clearly to understand the principle, to consult the works of the able authors whom we have named, to which we acknowledge ourselves so much indebted. If these views are correct, there is then no danger that the accumulated capital which a sinking fund under particular circumstances might occasion, would not find employment, or that the commodities which it might be made to produce would not be beneficially sold, so as to afford an adequate profit to the producers. On this part of the subject it is only necessary to add, that there would be no necessity for stockholders to become farmers or manufacturers. There are always to be found in a great country a sufficient number of responsible persons, with the requisite skill, ready to employ the accumulated capital of others, and to pay to them a share of the profits, and which in all countries is known by the name of interest for borrowed money.

The second objection to the indefinite increase of the sinking fund remains now to be noticed. By the remission of taxes suddenly to the amount probably of thirty millions per annum, a great effect would be produced on the price of goods. "The fate of merchants, manufacturers, mechanics, and every description of dealers, in such an event, must be contemplated by every thinking man with alarm; for should the national debt be discharged, and such a weight of taxation taken off at once, all the goods remaining on hand would be, comparatively speaking, of no value to the holders, because, having been purchased or manufactured while such taxation prevailed, they must be undersold by all those who might manufacture the same kind of goods after such taxation had ceased." It is only, then, on the supposition that merchants, manufacturers, and dealers, would be affected as above described, that any evil would result from the largest remission of taxes. It would not of course be said, that by remitting a tax of L.5 to A, L.10 to B, L.100 to C, and so on, any injury would be done to them. If they added these different sums to their respective capitals, they would augment their permanent annual revenue, and would be contributing to the increase of the mass of commodities, thereby adding to the general abundance. We have already, we hope, successfully shown that an augmentation of capital is neither injurious to the individual by whom it is saved, nor to the community at large; its tendency is to increase the demand for labour, and consequently the population, and to add to the power and strength of the country. But they will not add these respective sums to their capitals; they will expend them as revenue! The measure cannot be said to be either injurious to themselves or to the community on that account. They annually contributed a portion of their produce to the stockholder in payment of debt, who immediately employed it as capital; that portion of produce is now at their own disposal; they may consume it themselves if they please. A farmer who used to sell a portion of his corn for the particular purpose of furnishing this tax, may consume this corn himself; he may get the distiller to make gin of it, or the brewer to turn it into beer, or he may exchange it for a portion of the cloth which the clothier, who is now released from the tax as well as the farmer, is at liberty to dispose of for any commodity which he may desire. It may indeed be said, where is all this cloth, beer, gin, &c. to come from; there was no more than necessary for the general demand before this remission of taxes; if every man is now to consume more, from whence is this supply to be obtained? This is an objection of quite an opposite nature to that which was before urged. Now, it is said there would be too much demand and no additional supply; before, it was contended that the supply would be so great that no demand would exist for the quantity supplied. One objection is no better founded than the other. The stockholders, by previously receiving the payment of their debt, and employing the funds they received productively, or lending them to some other persons who would so employ them, would produce the very additional commodities which the society at large would have it in their power to consume. There would be a general augmentation of revenue, and a general augmentation of enjoyment; and it must not for a moment be supposed that the increased consumption of one part of the people would be at the expense of another part. The good would be unmixed, and without alloy. It remains then only to consider the injury to traders from the fall in the price of goods; and the remedy against this appears to be so very simple, that it surprises us that it should ever have been urged as an objection. In laying on a new tax, the stock in hand of the article taxed is commonly ascertained; and, as a measure of justice, the dealer in such article is required to pay the imposed tax on his stock. Why may not the reverse of this be done? Why may not the tax be returned to each individual on his stock in hand, whenever it shall be thought expedient to take off the tax from the article which he manufactures, or in which he deals? It would only be necessary to continue the taxes for a very short time for this purpose. On no view of this question can we see any validity in the arguments which we have quoted, and which were so particularly insisted on by Mr Vansittart.

There are some persons who think that a sinking fund, even when strictly applied to its object, is of no national benefit whatever. The money which is contributed, they say, would be more productively employed by the payers of the taxes than by the commissioners of the sinking fund. The latter purchase stock with it, which probably does not yield five per cent.; the former would obtain from the employment of the same capital much more than five per cent., consequently the country would be enriched by the difference. There would be in the latter case a larger nett supply of the produce of our land and labour, and that is the fund from which ultimately all our expenditure must be drawn. Those who maintain this opinion do not see that the commissioners merely receive money from one class of the community, and pay it to another class, and that the real question is, Which of these two classes will employ it most productively? Forty millions per annum are raised by taxes, of which twenty millions, we will suppose, is paid for sinking fund, and twenty millions for interest of debt. After a year's purchase is made by the commissioners, this forty millions will be divided differently; nineteen millions will be paid for interest, and twenty-one millions for sinking fund; and so from year to year, though forty millions is always paid on the whole, a less and less portion of it will be paid for interest, and a larger portion for sinking fund, till the commissioners have purchased the whole amount of stock, and then the whole forty millions will be in the hands of the commissioners. The sole question then with regard to profits is, whether those who pay this forty millions, or those who receive it, will employ it most productively; the commissioners, in fact, never employing it at all, their business being to transfer it to those who will employ it. Now, of this we are quite certain, that all the money received by the stockholder in return for his stock must be employed as capital; for if it were not so employed, he would be deprived of his revenue, on which he had habitually depended. If then the taxes which are paid towards the sinking fund be derived from the revenue of the country, and not from its capital, by this operation a portion of revenue is yearly realized into capital, and consequently the whole revenue of the society is increased; but it might have been realized into capital by the payer of the tax if there had been no sinking fund, and he had been allowed to retain the money to his own use. It might so, and if it had been so disposed of, there can be no advantage in respect to the accumulation of the wealth of the whole society by the establishment of the sinking fund; but it is not so probable that the payer of the tax would make this use of it as the receiver. The receiver, when he gets paid for his stock, only substitutes one capital for another; and he is accustomed to look to his capital for all his yearly income. The payer will have all that he paid in addition to his former revenue; if the sinking fund be discontinued he may indeed realize it into capital, but he may also use it as revenue, increasing his expenditure on wine, houses, horses, clothes, &c. The payer might too have paid it from his capital; and therefore the employment of one capital might be substituted for another. In this case, too, no advantage arises from the sinking fund, as the national wealth would accumulate as rapidly without it as with it; but if any portion of the taxes paid expressly for the sinking fund be paid from revenue, and which, if not so paid, would have been expended as revenue, then there is a manifest advantage in the sinking fund, as it tends to increase the annual produce of our land and labour; and as we cannot but think that this would be its operation, we are clearly of opinion that a sinking fund, honestly applied, is favourable to the accumulation of wealth.

Dr Hamilton has followed Dr Price in insisting much on the disadvantage of raising loans during war in a three per cent. stock, and not in a five per cent. stock. In the former, a great addition is made to the nominal capital, which is generally redeemed during peace at a greatly advanced price. Three per cents which were sold at sixty will probably be repurchased at eighty, and may come to be bought at 100; whereas in five per cents there would be little or no increase of nominal capital, and as all the stocks are redeemable at par, they would be paid off with very little loss. The correctness of this observation must depend on the relative prices of these two stocks. During the war in 1798, the three per cents were at fifty, while the five per cents were at seventy-three; and at all times the five per cents bear a very low relative price to the three per cents. Here then is one disadvantage to be put against another, and it must depend upon the degree in which the prices of the three per cents and five per cents differ, whether it be more desirable to raise the loan in the one or in the other. We have little doubt, that during many periods of the war, there would have been a decided disadvantage in making the loan in five per cent. stock in preference to three per cent. stock. The market in five per cent. stock, too, is limited; a sale cannot be forced in it without causing a considerable fall, a circumstance known to the contractors, and against which they would naturally take some security in the price which they bid for a large loan if in that stock. A premium of two per cent. on the market price may appear to them sufficient to compensate them for their risk in a loan in three per cent. stock; they may require one of five per cent. to protect them against the dangers they apprehend from taking the same loan in a five per cent. stock.

II. After having duly considered the operation of a sinking fund derived from annual taxes, we come now to the consideration of the best mode of providing for our annual expenditure, both in war and peace; and further, to examine whether a country can have any security that a fund raised for the purpose of paying debt will not be misapplied by ministers, and be really made the instrument for creating new debt, so as never to afford a rational hope that any progress whatever will permanently be made in the reduction of debt.

Suppose a country to be free from debt, and a war to take place which should involve it in an annual additional expenditure of twenty millions—there are three modes by which this expenditure may be provided; first, taxes may be raised to the amount of twenty millions per annum, from which the country would be totally freed on the return of peace; or, secondly, the money might be annually borrowed and funded, in which case, if the interest agreed upon was five per cent. a perpetual charge of one million per annum taxes would be incurred for the first year's expense, from which there would be no relief during peace, or in any future war,—of an additional million for the second year's expense, and so on for every year that the war might last. At the end of twenty years, if the war lasted so long, the country would be perpetually encumbered with taxes of twenty millions per annum, and would have to repeat the same course on the recurrence of any new war. The third mode of providing for the expenses of the war would be to borrow annually the twenty millions required as before, but to provide by taxes a fund, in addition to the interest, which, accumulating at compound interest, should finally be equal to the debt. In the case supposed, if money was raised at five per cent. and a sum of L.200,000 per annum in addition to the million for interest were provided, it would accumulate to twenty millions in forty-five years; and, by consenting to raise L.1,200,000 per annum by taxes for every loan of twenty millions, each loan would be paid off in forty-five years from the time of its creation; and in forty-five years from the termination of the war, if no new debt were created, the whole would be redeemed, and the whole of the taxes would be repealed.

Of these three modes, we are decidedly of opinion that the preference should be given to the first. The burdens of the war are undoubtedly great during its continuance, but at its termination they cease altogether. When the pressure of the war is felt at once, without mitigation, we shall be less disposed wantonly to engage in an expensive contest; and, if engaged in it, we shall be sooner disposed to get out of it, unless it be a contest for some great national interest. In point of economy, there is no real difference in either of the modes; for twenty millions in one payment, one million per annum for ever, or L.1,200,000 for forty-five years, are precisely of the same value; but the people who pay the taxes never so estimate them, and therefore do not manage their private affairs accordingly. We are too apt to think that the war is burdensome only in proportion to what we are at the moment called to pay for it in taxes, without reflecting on the probable duration of such taxes. It would be difficult to convince a man possessed of L.20,000, or any other sum, that a perpetual payment of L.50 per annum was equally burdensome with a single tax of L.1000. He would have some vague notion that the L.50 per annum would be paid by posterity, and would not be paid by him; but if he leaves his fortune to his son, and leaves it charged with this perpetual tax, where is the difference whether he leaves him L.20,000 with the tax, or L.19,000 without it? This argument of charging posterity with the interest of our debt, or of relieving them from a portion of such interest, is often used by otherwise well-informed people; but we confess we see no weight in it. It may indeed be said that the wealth of the country may increase, and as a portion of the increased wealth will have to contribute to the taxes, the proportion falling on the present amount of wealth will be less, and thus posterity will contribute to our present expenditure. That this may be so, is true: but it may also be otherwise; the wealth of the country may diminish; individuals may withdraw from a country heavily taxed; and therefore the property retained in the country may pay more than the just equivalent, which would at the present time be received from it. That an annual tax of L.50 is not deemed the same in amount as L.1000 ready money, must have been observed by every body. If an individual were called upon to pay L.1000 to the income-tax, he would probably endeavour to save the whole of it from his income; he would do no more if, in lieu of this war-tax, a loan had been raised, for the interest of which he would have been called upon to pay only L.50 income-tax. The war-taxes, then, are more economical; for when they are paid, an effort is made to save to the amount of the whole expenditure of the war, leaving the national capital undiminished. In the other case, an effort is only made to save to the amount of the interest of such expenditure, and therefore the national capital is diminished in amount. The usual objection made to the payment of the larger tax is, that it could not be conveniently paid by manufacturers and landholders, for they have not large sums of money at their command. We think that great efforts would be made to save the tax out of their income, in which case they could obtain the money from this source; but suppose they could not, what should hinder them from selling a part of their property for money, or of borrowing it at interest? That there are persons disposed to lend, is evident from the facility with which government raises its loans. Withdraw this great borrower from the market, and private borrowers would be readily accommodated. By wise regulations and good laws, the greatest facilities and security might be afforded to individuals in such transactions. In the case of a loan, A advances the money, and B pays the interest, and every thing else remains as before. In the case of war-taxes, A would still advance the money and B pay the interest, only with this difference, he would pay it directly to A; now he pays it to government, and government pays it to A.

These large taxes, it may be said, must fall on property, which the smaller taxes now do not exclusively do. Those who are in professions, as well as those who live from salaries and wages, and who now contribute annually to the taxes, could not make a large ready money payment; and they would therefore be benefited at the expense of the capitalist and landholder. We believe that they would be very little, if at all, benefited by the system of war-taxes. Fees to professional men, salaries, and wages, are regulated by the prices of commodities, and by the relative situation of those who pay and of those who receive them. A tax of the nature proposed, if it did not disturb prices, would, however, change the relation between these classes, and a new arrangement of fees, salaries, and wages, would take place, so that the usual level would be restored.

The reward that is paid to professors, &c. is regulated, like every thing else, by demand and supply. What produces the supply of men, with certain qualifications, is not any particular sum of money, but a certain relative position in society. If you diminish, by additional taxes, the incomes of landlords and capitalists, leaving the pay of professions the same, the relative position of professions would be raised; an additional number of persons would therefore be enticed into those lines, and the competition would reduce the pay.

The greatest advantage that would attend war-taxes would be the little permanent derangement that they would cause to the industry of the country. The prices of our commodities would not be disturbed by taxation; or if they were, they would only be so during a period when every thing is disturbed by other causes during war. At the commencement of peace every thing would be at its natural price again, and no inducement would be afforded to us by the direct effect, and still less by the indirect effect, of taxes on various commodities, to desert employments in which we have peculiar skill and facilities, and engage in others in which the same skill and facilities are wanting. In a state of freedom every man naturally engages himself in that employment for which he is best fitted, and the greatest abundance of products is the result. An injudicious tax may induce us to import what we should otherwise have produced at home, or to export what we should otherwise have received from abroad; and in both cases we shall receive, besides the inconvenience of paying the tax, a less return for a given quantity of our labour than what that labour would, if unfettered, have produced. Under a complicated system of taxation, it is impossible for the wisest legislature to discover all the effects, direct and indirect, of its taxes; and if it cannot do this, the industry of the country will not be exerted to the greatest advantage. By war-taxes, we should save many millions in the collection of taxes. We might get rid of at least some of the expensive establishments, and the army of officers which they employ would be dispensed with. There would be no charges for the management of debt. Loans would not be raised at the rate of L.50 or L.60 for a nominal capital of L.100, to be repaid at L.70, L.80, or possibly at L.100; and perhaps, what is of more importance than all these together, we might get rid of those great sources of the demoralization of the people, the Customs and Excise. In every view of this question we come to the same conclusion, that it would be a great improvement in our system for ever to get rid of the practice of funding. Let us meet our difficulties as they arise, and keep our estates free from permanent encumbrances, of the weight of which we are never truly sensible till we are involved in them past remedy.

We are now to compare the other two modes of defraying the expenses of a war, one by borrowing the capital expended, and providing annual taxes permanently for the payment of the interest; the other by borrowing the capital expended, and, besides providing the interest by annual taxes, raising, by the same mode, an additional revenue (and which is called the sinking fund), with a view, within a certain determinate time, to redeem the original debt, and get rid entirely of the taxes.

Under the firm conviction that nations will at last adopt the plan of defraying their expenses, ordinary and extraordinary, at the time they are incurred, we are favourable to every plan which shall soonest redeem us from debt; but then we must be convinced that the plan is effective for the object. This, then, is the place to examine whether we have or can have any security for the due application of the sinking fund to the payment of debt.

When Mr Pitt, in 1786, established the sinking fund, he was aware of the danger of intrusting it to ministers and parliament; and therefore provided that the sums applicable to the sinking fund should be paid by the exchequer into the hands of commissioners, by quarterly payments, who should be required to invest equal sums of money in the purchase of stock, on four days in each week, or about fifty days in each quarter. The commissioners named were, the Speaker of the House of Commons, the Chancellor of the Exchequer, the Master of the Rolls, the Accountant-General of the Court of Chancery, and the Governor and Deputy-Governor of the Bank. He thought that, under such management, there could be no misapplication of the funds, and he thought correctly, for the commissioners have faithfully fulfilled the trust reposed in them. In proposing the establishment of a sinking fund to parliament in 1786, Mr Pitt said, "With regard to preserving the fund to be invariably applied to the diminution of the debt inalienable, it was the essence of his plan to keep that sacred, and most effectually so in time of war. He must contend, that to suffer the fund at any time, or on any pretence, to be diverted from its proper object, would be to ruin, defeat, and overturn his plan. He hoped, therefore, when the bill he should introduce should pass into a law, that house would hold itself solemnly pledged not to listen to a proposal for its repeal on any pretence whatever."

"If this million, to be so applied, is laid out with its growing interest, it will amount to a very great sum in a period that is not very long in the life of an individual, and but an hour in the existence of a great nation; and this will diminish the debt of this country so much as to prevent the exigencies of war from raising it to the enormous height it has hitherto done. In the period of twenty-eight years, the sum of a million, annually improved, would amount to four millions per annum; but care must be taken that this fund be not broken in upon: *this has hitherto been the bane of this country;* for if the original sinking fund had been properly preserved, it is easy to be proved that our debts, at this moment, would not have been very burdensome: *this has hitherto been in vain endeavoured to be prevented by acts of parliament;* the minister has uniformly, when it suited his convenience, gotten hold of this sum, which ought to have been regarded as most sacred. What then is the way of preventing this? The plan I mean to propose is this, that this sum be vested in certain commissioners, to be by them applied quarterly to buy up stock; by this means, no sum so great will ever be ready to be seized upon on any occasion, and the fund will go on without interruption. Long and very long has this country struggled under its heavy load, without any prospect of being relieved; but it may now look forward to an object upon which the existence of this country depends; it is therefore proper it should be fortified as much as possible against alienation. By this manner of paying L.250,000 quarterly into the hands of commissioners, it would make it impossible to take it by stealth; and the advantage would be too well felt ever to suffer a public act for that purpose. A minister could not have the confidence to come to this house and desire the repeal of so beneficial a law, which tended so directly to relieve the people from burden."

Mr Pitt flattered himself most strangely, that he had found a remedy for the difficulty which "had hitherto been the bane of this country:" he thought he had discovered means for preventing "ministers, when it suited their convenience, from getting hold of this sum, which ought to be regarded as most sacred." With the knowledge of parliament which he had, it is surprising that he should have relied so firmly on the resistance which the House of Commons would offer to any plan of ministers for violating the sinking fund. Ministers have never desired the partial repeal of this law, without obtaining a ready compliance from parliament.

We have already shown, that in 1807, one chancellor of the exchequer proposed to relieve the country from taxation, with a very slight exception, for several years together, while we were, during war, keeping up, if not increasing, our expenditure, and supplying it by means of annual loans. What is this but disposing of a fund which ought to have been regarded as most sacred?

In 1809, another chancellor of the exchequer raised a loan, without raising any additional taxes to pay the interest of it, but pledged a portion of the war-taxes for that purpose, thereby rendering an addition to that amount necessary to the loan of the following and every succeeding year. Was not this disposing of the sinking fund by stealth, and accumulating debt at compound interest? Another chancellor of the exchequer, in 1813, proposed a partial repeal of the law, by which seven millions per annum of the sinking fund was placed at his disposal, and which he has employed in providing for the interest of new debt. This was done with the sanction of parliament, and, as we apprehend, in direct violation of all the laws which had before been passed regarding the sinking fund. But what has become of the remainder of this fund, after deducting the seven millions taken from it by the act of 1813?[1] It should now be sixteen millions, and at that amount it was returned in the annual finance accounts last laid before parliament. The finance committee appointed by the House of Commons did not fail to see that nothing can be deemed an efficient fund for the redemption of debt in time of peace, but such as arises from an excess of revenue above expenditure; and as that excess, under the most favourable view, was not quite two millions, they considered that sum as the real efficient sinking fund, which was now applicable to the discharge of debt. If the act of 1802 had been complied with, if the intentions of Mr Pitt had been fulfilled, we should now have had a clear excess of revenue of above twenty millions, applicable to the payment of the debt; as it is, we have two millions only, and if we ask ministers what has become of the remaining eighteen millions, they show us an expensive peace establishment, which they have no other means of defraying but by drafts on this fund, or several hundred millions of three per cents, on which it is employed in discharging the interest. If ministers had not had such an amount of taxes to depend on, would they have ventured, year after year, to encounter a deficiency of revenue below expenditure, for several years together, of more than twelve millions? It is true that the measures of Mr Pitt locked it up from their immediate seizure; but they knew it was in the hands of the commissioners, and presumed as much upon it, and justly, with the knowledge they had of parliament, as if it had been in their own. They considered the commissioners as their trustees, accumulating money for their benefit, and of which they knew that they might dispose whenever they should consider that the urgency of the case required it. They seem to have made a tacit agreement with the commissioners, that they should accumulate twelve millions per annum at compound interest, while they themselves accumulated an equal amount of debt, also at compound interest. The facts are indeed no longer denied. In the last session of parliament, for the first time, the delusion was acknowledged by ministers, after it had become manifest to every other person; but yet it is avowed to be their intention to go on with this nominal sinking fund, raising a loan every year for the difference between its real and nominal amount, and letting the commissioners subscribe to it. On what principle this can be done, it would be difficult to give any rational account. Perhaps it may be said that it would be a breach of faith to the stockholder to take away the sinking fund; but is it not equally a breach of faith if the government itself sells to the commissioners the greatest part of the stock which they buy? The stockholder wants something substantial and real to be done for him, and not any thing deceitful and delusive. Disguise it as you will, if of fourteen millions to be invested by the commissioners in time of peace, the stock which twelve millions will purchase is sold by the government itself, which creates it for the very purpose of obtaining these twelve millions, and only stock for two millions is purchased in the market, and no taxes for sinking fund or interest are provided for the twelve millions which government takes; the result is precisely the same to the stockholder, and to every one concerned, as if the sinking fund was reduced to two millions. It is utterly unworthy of a great country to countenance such pitiful shifts and evasions.

---

[1] Some of the following observations refer to the period when this article was originally written.—Ed.

The sinking fund, then, has, instead of diminishing the debt, greatly increased it. The sinking fund has encouraged expenditure. If, during war, a country spends twenty millions per annum, in addition to its ordinary expenditure, and raises taxes only for the interest, it will in twenty years accumulate a debt of four hundred millions, and its taxes will increase to twenty millions per annum. If, in addition to the million per annum, taxes of L.200,000 were raised for a sinking fund, and regularly applied to the purchase of stock, the taxes, at the end of twenty years, would be twenty-four millions, and its debt only three hundred and forty-two millions; for fifty-eight millions will have been paid off by the sinking fund; but if at the end of this period new debt shall be contracted, and the sinking fund itself, with all its accumulations, amounting to L.6,940,000, be absorbed in the payment of interest on such debt, the whole amount of debt will be five hundred and thirty-eight millions, exceeding that which would have existed if there had been no sinking fund by a hundred and thirty-eight millions. If such an additional expenditure were necessary, provision should be made for it without any interference with the sinking fund. If, at the end of the war, there is not a clear surplus of revenue above expenditure of L.6,940,000 on the above supposition, there is no use whatever in persevering in a system which is so little adequate to its object. After all our experience, however, we are again toiling to raise a sinking fund; and in the last session of parliament three millions of new taxes were voted, with the avowed object of raising the remnant of our sinking fund, now reduced to two millions, to five millions. Is it rash to prognosticate that this sinking fund will share the fate of all those which have preceded it? Probably it will accumulate for a few years, till we are engaged in some new contest, when ministers, finding it difficult to raise taxes for the interest of loans, will silently encroach on this fund; and we shall be fortunate if, in their next arrangement, we shall be able to preserve out of its wreck an amount so large as two millions.

It is, we think, sufficiently proved that no securities can be given by ministers that the sinking fund shall be faithfully devoted to the payment of debt, and without such securities we should be much better without such a fund. To pay off the whole, or a great portion of our debt, is, in our estimation, a most desirable object, if, at the same time, we acknowledged the evils of the funding system, and resolutely determined to carry on our future contests without having recourse to it. This cannot, or rather will not, be done by a sinking fund as at present constituted, nor by any other that we can suggest; but if, without raising any fund, the debt were paid by a tax on property, once for all, it would effect its object. Its operation might be completed in two or three years during peace; and if we mean honestly to discharge the debt, we do not see any other mode of accomplishing it. The objections to this plan are the same as those which we have already attempted to answer in speaking of war-taxes. The stockholders, being paid off, would have a large mass of property, for which they would be eagerly seeking employment. Manufacturers and landholders would want large sums for their payments into the exchequer. These two parties would not fail to make an arrangement with each other, by which one party would employ their money, and the other raise it. They might do this by loan, or by sale and purchase, as they might think it most conducive to their respective interests; with this the state would have nothing to do. Thus, by one great effort, we should get rid of one of the most terrible scourges which was ever invented to afflict a nation; and our commerce would be extended without being subject to all the vexatious delays and interruptions which our present artificial system imposes upon it.

There cannot be a greater security for the continuance of peace, than the imposing on ministers the necessity of applying to the people for taxes to support a war. Suffer the sinking fund to accumulate during peace to any considerable sum, and very little provocation would induce them to enter into a new contest. They would know that, by a little management, they could make the sinking fund available to the raising of a new supply, instead of being available to the payment of the debt. The argument is now common in the mouths of ministers, when they wish to lay on new taxes, for the purpose of creating a new sinking fund, in lieu of one which they have just spent, to say, "It will make foreign countries respect us; they will be afraid to insult or provoke us, when they know that we are possessed of so powerful a resource." What do they mean by this argument, if the sinking fund be not considered by them as a war fund, on which they can draw in support of the contest? It cannot, at one and the same time, be employed in the annoyance of an enemy, and in the payment of debt. If taxes are, as they ought to be, raised for the expenses of a war, what facility will a sinking fund give to the raising of them? none whatever. It is not because the possession of a sinking fund will enable them to raise new and additional taxes that ministers prize it; for they know it will have no such effect; but because they know that they will be enabled to substitute the sinking fund in lieu of taxes, and employ it, as they have always done, in war, and providing interest for fresh debt. Their argument means this, or it means nothing; for a sinking fund does not necessarily add to the wealth and prosperity of a country; and it is on that wealth and prosperity that it must depend, whether new burdens can be borne by the people. What did Mr Vansittart mean in 1813, when he said that "the advantage which his new plan of finance would hereafter give, in furnishing a hundred millions in time of peace, as a fund against the return of hostilities, was one of great moment. This would place an instrument of force in the hands of parliament, which might lead to the most important results." "It might be objected by some, that keeping in reserve a large fund to meet the expenses of a new war, might be likely to make the government of this country arrogant and ambitious, and therefore have a tendency unnecessarily to plunge us in new contests;" not a very unreasonable objection, we should think. How does Mr Vansittart answer it? "On this subject he would say, from long experience and observation, that it would be better for our neighbours to depend on the moderation of this country, than for this country to depend on them. He should not think the plan objectionable on this account. If the sums treasured up were misapplied by the arrogant or ambitious conduct of our government, the blame must fall on the heads of those who misused it, not on those who put it into their hands for purposes of defence. They did their duty in furnishing the means of preserving the greatness and glory of the country, though those means might be used for the purposes of ambition, rapine, and desolation." These are very natural observations from the mouth of a minister; but we are of opinion that such a treasure would be more safe in the custody of the people, and that parliament have something more to do than to furnish ministers with the means of preserving the greatness and glory of the country. It is their duty to take every security that the resources of the country are not misapplied "by the arrogant and ambitious conduct of our government," or "used for the purposes of ambition, rapine, and desolation."

On the extraordinary assumption that there was any thing in Mr Vansittart's plan that would more effectually than the old plan allow a hundred millions hereafter to be appropriated to the public service, Dr Hamilton has the following observations:

"We are altogether at a loss to form a distinct conception of the *valuable treasure* here held forth. So soon as any stock is purchased by the commissioners, and stands invested in their name, a like amount of the public debt is in fact discharged. Whether a parliamentary declaration to the effect be made or not, is only a matter of form. If the money remain invested in the name of the commissioners, no doubt it may be transferred again to purchasers in the stock exchange when war broke out anew; and money may be raised for the public in this manner. It is an application to the public to invest their capital in the purchase of this dormant stock." "It is true, that if the taxes imposed during war for the purpose of a sinking fund be continued after peace is restored, till a large sum (suppose L.100,000,000) be vested in the hands of the commissioners, the public, upon the renewal of the war, may spend to that amount without imposing fresh taxes; an advantage," observes Mr Huskisson, "not only not exclusively belonging to this plan, but unavoidable under any plan of a sinking fund in time of peace." Mr Vansittart ought to have said, "if our sinking fund should accumulate in time of peace to so large a sum that I can take five millions per annum from it, I can spend L.100,000,000 in a new war without coming to you for fresh taxes: the disadvantages of my plan are, that by now taking L.7,000,000 per annum from it, and making a provision for speedily, and at regular intervals, appropriating more of this fund to present objects, the sinking fund will be so much diminished that I cannot so soon, by a great many years, avail myself of the five millions for the purpose which I have stated." (D. R.)

The year 1825 found L.5,000,000 appropriated to a sinking fund, but this was reduced to L.3,000,000, and even then it was found that it could not be continued with advantage to the nation, and in the year 1828 a committee was appointed by the House of Commons to consider the question, which, after full consideration, came to the only reasonable conclusion, that the true principle upon which to calculate the amount applicable as a sinking fund for the redemption of the debt was the excess of revenue over expenditure. But this decision did not cause the sound policy to be observed, and the deficiency bills payable out of current revenue were met by the fund destined for the extinction of the debt, and so the whole history of the sinking fund, from 1716 up to the last moment, goes to demonstrate the obvious fact that the redemption of the debt by the application of borrowed capital to the purchase of stock is a sham and a delusion, and that the accumulation by any means of a large amount of the securities of the state in the hands of commissioners, has failed in its purpose of securing inviolate the sinking fund for its destined purpose. The only means of diminishing the burden of the national debt is by employing our surplus revenue for that purpose, and it appears to us that the only efficacious manner of so employing it is by the purchase of stock by the state, to cancel and expunge it at once and for ever, so that the surplus revenue of the country would be larger every year by the amount of the interest on the stock cancelled from the period of the commencement of the operation.

Thus it would be out of the power of the minister to retransfer to the public the stock redeemed, in order to apply it to any extraordinary expenditure, and if he did not apply to the people for taxes to support a war, at all events he must come to them for authority to raise the required means by loan, a process which they can understand, and which admits of no mystification. And the sale to the public, by commissioners in whom the stock accumulated under the old system is vested, is neither more nor less than a loan, the purchasers being, in fact, the lenders to the state of the money received for the stock sold.

But these financial operations must be viewed practically as well as theoretically. It has been shown that an accumulated sinking fund never has been preserved inviolate for application to the purpose for which it was designed, and in the same manner an accumulating excess of revenue over expenditure comes with its embarrassment to a finance minister in proportion to its amount. Every tax is more or less inconvenient, not to say oppressive; and when the taxpayer sees at the disposal of the minister the means of its entire or partial repeal he is not disposed to continue its payment beyond the immediate exigency of the time, nor to exchange the present relief which he will experience from its remission for any prospective advantage whatever. Thus, if every year there remained a surplus by which the interest of the debt could be diminished, and this surplus increased in a compound ratio by the diminution otherwise of the charge on the consolidated fund, the people through their representatives in parliament would, in all probability, insist on its application to their present rather than to their future and more solid advantage. Since the adoption of a liberal fiscal policy a large amount of taxation has been repealed. We should have made great progress in the diminution of our debt if we had annually cancelled an equal amount of consols, but we should have failed to give direct relief to the manufacturers and consumers of glass, and soap, and bricks, and other articles upon which the tax has been repealed, and these would not have been satisfied if, with a large surplus revenue, they had been told that in some fifty or sixty years a taxation of L.27,000,000 would be at one blow remitted, in proof of which it may be observed, that among the numerous financial projects which have been contemplated by various administrations for the disposal of the long annuities in the year 1860, when an annual charge of L.1,294,447, and in the year 1867, when a further annuity of L.585,740 will expire, the reduction of the debt has scarcely been mentioned.

In the year 1854, when the unparalleled and increasing prosperity of the empire was rudely interrupted by the breaking out of the Russian war, the Chancellor of the Exchequer announced in Parliament his intention to carry on the expenditure from the income of the country, and to make taxation support the war. But though he did not remain in office long enough to be compelled officially to acknowledge it himself, this was at once discovered to be impracticable by his successor, and in the very first year after the commencement of hostilities L.14,475,000 of increased taxation having been imposed, and found to be less by L.15,721,000 than was required, the government did not deem it possible to induce the House of Commons to submit to so large an additional impost, and were compelled to raise L.16,000,000 by loan, entailing a permanent annual charge of L.480,000, and a further charge of L.116,000 terminable in thirty years.

It was seen with regret by all those who coincide in the principles here enunciated, that the fallacious system to which so many eminent authorities have objected of the old sinking fund, was on this occasion revived by a clause inserted in the bill authorising the loan, which was intended to provide for the future extinction of the debt of L.16,000,000 then incurred, by pledging parliament to an annual payment of L.1,000,000 during sixteen years, to commence at the termination of the Russian war. It is difficult to understand the object of the Chancellor of the Exchequer in volunteering to enter into this engagement with the stock-holder, as while it could not fail to fetter him in his future operations, it was of scarcely any available value to him in the negotiation of his loan.

Although in the then temper of the House of Commons, indignant at the previous parsimony and want of energy which they conceived to have occasioned great disaster to our army in the Crimea, no opposition was made to the whole proposition, nevertheless this part of it did not pass without comment and animadversion. In the House of Lords Lord Monteagle protested strongly against it. "This prospective engagement," he said, "assumed that there would either be a surplus revenue of L.1,000,000 a year, or that parliament would be justified in adding L.1,000,000 a year to the taxation of the country, in order to provide L.1,000,000 annually to apply to the reduction of the debt just contracted. The only third alternative was that of a new loan, or, in other words, the old folly of paying debt with borrowed money. All experience proved that these prospective engagements could not be relied on . . . . It should be remembered that war was not only an expensive operation in itself, but that when it was brought to a close there were always heavy bills to pay, ships to be paid off, retired allowances to provide, in short, the close of war was even more expensive than war itself. Suppose then no surplus existed, and that parliament were unwilling to increase taxation, if money should have been borrowed in time of war, and that at its termination money should have to be borrowed for the purpose of paying off the debt, that would be recurring to one of the most exploded blunders in finance, that of paying off the debt with borrowed money."

It is to be regretted that this fallacious system should have been disinterred, as it was avoidable, but it was practically unavoidable to raise as much as half the requirements of the war by taxation, and the minister was compelled, so far as respected L.16,000,000, to call upon the people for the interest instead of the principal of the war expenditure. And so it is to be feared we shall always find the actual practice opposed to the sound theory, and while on the one hand the nation will not have the courage to look its predominant difficulty fairly in the face, and endeavour to diminish or extinguish its debt by a great temporary sacrifice, we shall scarcely, in our time, see any sound, absolute, and defined system adopted to that end by the administrators of her finances, which will be impregnable to circumstances and independent of exigencies. And if we except the creation of terminable annuities, some of which do not expire till the year 1893, little has been done during nearly half a century of peace and prosperity to diminish the incumbrance of the country; and though the creation of this description of security has been a favourite system with financiers of later years as a means for the reduction of the debt, it may be questioned how far it is consistent with sound policy to create in such a manner a fixed sinking fund, which is always payable whether the revenue of the country be in surplus or deficit.

The following table details the progress of the funded debt of Great Britain for the last thirty-five years.

National Debt existing on 5th January in each year since 1820.

Year.	Unredeemed Debt.	Annual Interest payable.	Year.	Unredeemed Debt.	Annual Interest payable.
	L.	L.		L.	L.
1821	801,565,310	28,064,720	1839	761,347,690	24,135,179
1822	795,312,767	27,875,840	1840	766,547,684	24,290,239
1823	796,530,144	26,419,870	1841	766,371,725	24,283,939
1824	791,701,614	26,271,762	1842	772,530,758	24,444,230
1825	781,123,222	25,541,049	1843	773,068,340	24,459,842
1826	778,128,267	25,429,677	1844	772,169,092	24,432,019
1827	783,801,739	25,683,011	1845	769,193,644	23,719,147

1837	761,422,570	24,142,470	1854†	752,655,549	23,206,380
1838	762,275,188	24,165,239	1855[1]	751,645,818	22,557,355

* and † Jan. 5, and April 5, respectively.

Description of Stock at Jan. 5, 1821, *and March* 31, 1855.

	Debt.	Stock.	Annual Interest.
	L.539,947,506	3 per cents.	L.16,198,425
	30,642,128	3½ ...	1,072,474
	75,496,163	4 ...	3,019,846
	155,479,513	5 ...	7,773,975
1821	L.801,565,310		L.28,064,720
	L.3,007,775	2½ per cents.	L.75,194
	745,333,404	3 ...	22,360,002
	2,871,515	3½ ...	100,503
	433,124	5 ...	21,656
1855	L.751,645,818		L.22,557,355

---

[1] Since this return was compiled, the loan of 1855 has added L.16,000,000 to the capital, and L.596,000 to the interest of the debt, and it is to be feared that the continuance of the war will still further add largely to its amount.

	Unredeemed Debt.	Annual Interest.
At January 5, 1820	L.794,980,481	L.27,736,448
At March 31, 1855	751,645,818	22,557,355
Decrease between January 5, 1820, and March 31, 1855	L.43,334,663	L.5,179,093

Reduction of interest from 1821 *to* 1854 *inclusive.*

Stock purchased with sinking fund	L.1,932,346
Do. transferred for life annuities, and for annuities for terms of years	1,399,878
Do. transferred for redemption of land-tax	63,301
Do. unclaimed for ten years, and purchased with unclaimed dividends	88,737
Do. reduced from a higher to a lower rate of interest	17,372,483
Do. paid off	994,286
	L.21,851,031

Increase of interest during the same years.

Stock created by loans	L.1,805,396	
Do. by Exchequer bills funded	983,476	
Do. exchanged from a higher to a lower rate of interest	13,862,416	
Unclaimed stock re-transferred to the proprietors	20,697	
		16,671,985
Total reduction of interest		L.5,179,046

A detailed statement of the national debt, since the year 1820, specifying the description of stock, the interest payable on each description, the reduction or increase of interest payable each year, with the cause of such reduction or increase, and showing the amount of stock created or redeemed in each year, will be found in *Parliamentary Return*, 10th August 1855. (J. L. R.)

FUNDY, Bay of. See Nova Scotia.

FUNEN, or Fuhnen (Danish *Fyen*), an island in the Baltic, belonging to Denmark, and, after Seeland, the largest island of that kingdom. It lies between Seeland and the mainland of Denmark, being separated from the former by the Great Belt, and from the latter by the Little Belt,—between N. Lat. 55. 2. and 55. 38., and E. Long. 9. 42. and 10. 53. Area 1187 square miles. The surface is generally hilly, particularly in the S.W., but it seldom rises to above 400 feet. With the exception of the S.W. part, the soil is very fertile; but agriculture is still in a backward state. Its chief productions are barley, oats, buckwheat, rye, flax, hemp, hops, and fruits. The rearing of cattle and poultry receives considerable attention, and honey and wax are among its articles of export. The climate is humid and variable, but milder than that of Seeland. There are few manufacturing establishments, and their articles of clothing are chiefly of domestic manufacture. The capital of the island is Odensee. Fünen, with Langeland, Taasinge, and some smaller islands, forms a stift or province of Denmark, with, in 1850, 187,818 inhabitants.

FUNERAL RITES, ceremonies accompanying the interment of the dead.

Egyptians. One of the earliest nations who paid any particular respect to their dead were the Egyptians, the posterity of Ham, the first cultivators of idolatrous worship and superstition after the Deluge. This, no doubt, arose from their belief in the immortality of the soul, its migration into all kinds of animals, and its return to the human body, which they supposed to be within the term of 3000 years. Hence the great care with which they embalmed the dead, and the vast expense they incurred in building proper repositories for them. In fact they were more solicitous about tombs for the dead than about houses for the living. This is strikingly displayed in those stupendous excavations which were appropriated to the reception of the dead, as well as those structures above ground, such as the pyramids, in which some of their kings were entombed.

Among the Egyptians, when a person died, his parents and friends put on mourning habits and abstained from all banquets and entertainments. This mourning lasted from forty to seventy days, during which period the body was embalmed. (See Embalming.) This ceremony completed, it was restored to the friends, who placed it in a kind of open chest, which was preserved either in their houses or in the sepulchres of their ancestors. But before the dead were allowed to be deposited in the tomb, they underwent a solemn judgment. Of this remarkable custom we have a particular account in the first book of Diodorus Siculus. "Those who prepare to bury a relative give notice of the day intended for the ceremony to the judges and to all the friends of the deceased, informing them that the body will pass over the lake of that district to which the dead belonged; when, on the judges assembling, to the number of more than forty, and ranging themselves in a semicircle on the further side of the lake, the vessel, which those who superintend the funeral have prepared for this purpose, is set afloat. This vessel is managed by a pilot, called in the Egyptian language Charon (*fierce-eyed*); and hence they say, that Orpheus, travelling in old times into Egypt and seeing this ceremony, formed his fable of the infernal regions, partly from what he saw and partly from invention. The vessel being launched on the lake, before the coffin which contains the body is put on board, the law permits all who are so inclined to produce an accusation against it. If any one steps forth and proves that the deceased has led an evil life, the judges pronounce sentence, and the body is precluded from burial; but if the accuser is convicted of injustice in his charge he falls himself under a considerable penalty." Such is the description which Diodorus gives of this funeral judicature, to which even the kings of Egypt were subject. The same author asserts that many sovereigns had been thus judicially deprived of the honours of burial by the indignation of the people; and that the terrors of such a fate had the most salutary influence on the conduct of their kings.

Hebrews. The funeral rites amongst the Hebrews were solemn and magnificent. Upon the demise of any person, the relatives and friends of the deceased rent their clothes. This custom is still imitated, but with a due regard to economy, by the modern Jews, who only cut off a piece of their garment in token of affliction. It was usual to bend the dead person's thumb into the hand, and fasten it in that posture with a string, because the thumb having then the figure of the name of God, they thought the evil spirit would not dare to approach it. When they came to the burying-place, they made a speech to the dead in the following terms:—"Blessed be God, who has formed thee, fed thee, maintained thee, and taken away thy life. O dead, he knows your numbers, and shall one day restore your life;" and so on. After this they delivered the funeral oration upon the deceased; then said a prayer, called the "righteousness of judgment;" and, finally, turning the face of the dead body towards heaven, they cried out—"Go in peace."

Greeks. Amongst the ancient Greeks it was usual before the interment to place a piece of money in the mouth of the deceased, as Charon's fare for wafting the departed soul over the river Styx. This ceremony was considered unnecessary in those countries supposed to be situated in the neighbourhood of the infernal regions, and to lead thither by a direct road. The corpse was likewise furnished with a cake composed of flour, honey, and other ingredients, which was designed to appease the fury of Cerberus, and to procure the ghost a safe and quiet entrance to Hades. Whilst the corpse continued in the house, a vessel of water was placed before the door, that those concerned about the body might purify themselves by washing; the Greeks, as well as the Jews, believing that pollution was contracted by touching a dead body.

The ceremonies by which they expressed their sorrow for the death of their friends were various; but it seems to have been a constant rule to recede as much as possible in habit and behaviour from their ordinary customs. For this reason they abstained from banquets and entertainments; they divested themselves of all ornaments; and they tore, cut off, or shaved their hair, which they cast on the funeral pile, to be consumed with the remains of their deceased friend.

After interment followed the περίδειπνον, νεκρόδειπνον, τάφος, or feasts, at which the company used to appear crowned; and upon this occasion they spoke in praise of the dead, as far as they could go with truth, as it was esteemed a notorious wickedness to disregard truth in their eulogiums. And not only at these feasts, but even before the company quitted the sepulchre, they were sometimes entertained with a panegyric upon the deceased.

Athenians.

The Greek soldiers who died in battle had not only their tombs adorned with inscriptions showing their names, parentage, and exploits, but were also honoured with an oration in their praise. The custom among the Athenians in the interment of their soldiers was as follows:—"They used to place the bodies of their dead in tents three days before the funeral, that all persons might have an opportunity of recognising their relatives, and paying their last respects to them. Upon the fourth day a coffin of cypress was sent from every tribe to convey the bones of their own relatives; after which went a covered hearse, in memory of those whose bodies could not be found. All these, accompanied by a concourse of people, were carried to the public burying-place, called Cerameicos, and there interred. One oration was spoken in commendation of them all, and their monuments were adorned with pillars, inscriptions, and other ornaments usual about the tombs of the most honourable persons. The oration was pronounced by the fathers of the deceased persons who had acquitted themselves most valiantly. Thus, after the battle of Marathon, the fathers of Callimachus and Cynægyrus were appointed to pronounce the funeral oration. And on the return of the day upon which the solemnity was first held, the same oration was annually repeated."

Burying the dead in the earth seems to have been the most ancient practice amongst the Greeks, though that of burning the body came afterwards to be very general. It was customary to throw on the funeral pile those garments which the deceased had usually worn. The pile was lighted by one of his nearest relatives or friends, who made prayers and vows to the wind to assist the flames, that the body might quickly be reduced to ashes; and whilst the pile was burning, the friends of the deceased stood by it, called upon him, and poured out libations of wine.

Romans.

The funeral rites among the ancient Romans were very numerous. In the case of persons of distinction the body was kept seven days. It was also washed with warm water and anointed with oil. Lest the deceased was merely in a trance, his friends at intervals, with the view to arouse him, raised a shout. This last act was called *conclamatio.* The third conclamation was on the seventh day; when, if no signs of life appeared, the corpse was dressed and embalmed by the *pollinctores,* placed on a couch in the vestibule of the house, with its feet towards the door; while the outside of the gate, if the deceased were of rank, was hung with cypress boughs. In the course of these seven days before the dead was placed a small altar called *acerra*, on which perfumes were burnt; and the *libitinarii* (undertakers) provided articles necessary for the interment.

On the seventh day a public crier was sent about the city, inviting the people to the solemnization of the funeral in these words: *Exsequias L. Tit. filii, quibus est commodum ire, jam tempus est. Olus* (i. e. *ille*) *ex ædibus effertur.* The company being assembled, the last conclamation ended, and the couch was covered with purple. The procession then moved forward, headed by a trumpeter, who was followed by women called *præficæ*, singing songs in praise of the deceased. Lastly, the corpse followed, borne by the nearest relations; and if the person were of rank or dignity, images of all his predecessors were carried before him on poles. The deceased was followed by his children, kindred, and others, clad in mourning (*atrati*). From this act of following the corpse, these funeral rites were called *exsequiæ.* The deceased being thus brought to the rostra, the next of kin made a funeral oration in praise of him and his ancestors. The body was then carried to the *pyra* or funeral pile and burnt. The ashes were afterwards gathered; and the priest, sprinkling the company thrice with clean water, the eldest of the *præficæ* crying aloud, *Ilicet*, dismissed the people, who took their leave of the deceased in this form, *Vale, vale, vale; nos te ordine quo natura permiserit cuncti sequemur.* The ashes, enclosed in an urn, were deposited in the sepulchre or tomb.

Christians.

The ancient Christians testified their abhorrence of the Pagan custom of burning the dead, and always deposited the body entire in the ground; and it was usual to bestow the honour of embalming upon the martyrs at least, if not upon others. They prepared the body for burial by washing it with water, and dressing it in funeral attire. The exportation or carrying forth of the body was performed by near relations, or by persons of such dignity as appeared consistent with the circumstances of the deceased. The singing of psalms was the chief ceremony in the funeral processions of the early Christians.

Roman Catholics.

In the Roman Catholic Church, the body of the deceased is washed, and a crucifix is put in its hand. At its feet is placed a vessel full of holy water, with a sprinkler, that those who come in may sprinkle both themselves and the body. A priest also stands by the corpse, and prays for the deceased. In the funeral procession the exorcist walks first, carrying the holy water, next the cross-bearer, afterwards the rest of the clergy, and lastly the officiating priest. They sing the *miserere* and some other psalms; and at the end of each psalm a *requiem.* We learn from Alet's ritual that the faces of deceased laymen must be turned towards the altar when they are placed in the church, and those of the clergy towards the people. The corpse is placed in the church, and surrounded with lighted tapers: after the office for the dead, mass is said; then the officiating priest sprinkles the corpse thrice with holy water, and as often throws incense on it. The body being laid in the grave, the officiating priest sprinkles it with holy water.

Greek Church.

The funeral ceremonies of the Greek Church are much the same with those of the Latin. It needs only to be observed, that after the funeral service they kiss the crucifix, and salute the mouth and forehead of the deceased; after which each of the company eats a piece of bread and drinks a glass of wine in the church, wishing the soul a good repose, and the afflicted family all consolation. (See also Burial; Burning of the Dead; and Burying-Place.)

Funeral *Games.* It was customary for persons of rank among the ancient Greeks and Romans to institute games, with all sorts of exercises, to do honour to the *manes* of their deceased friends. Patroclus's funeral games occupy the greater part of Book xxiii. of the Iliad; and Homer introduces Agamemnon's ghost, telling the ghost of Achilles that he had been a spectator at a great number of such solemnities.

Greeks.

The funeral games of the Greeks consisted chiefly of horse-races. The prizes were of different kinds and value, according to the rank and magnificence of the person who instituted them. The garlands given to victors on the occasion usually consisted of parsley, which was thought to have some relation to the dead.

Romans and Gauls.

These games, among the Romans, consisted chiefly of processions, and sometimes of mortal combats of gladiators around the funeral pile. In very early times they, as well as the Greeks, were accustomed to slay a number of captives and slaves before the pile, as victims to appease the manes of the deceased. Cæsar relates that the Gauls also observed this sanguinary custom.

FUNERAL *Oration*, a discourse pronounced in praise of a person deceased, at the ceremony of his funeral. This custom is very ancient. In the latter part of the account given of the Egyptian ceremonies of interment may be perceived the first rudiments of funeral orations, which were afterwards moulded into a more regular form by other nations who adopted this custom. Nor should it be omitted to be remarked, that those funeral solemnities were attended not only with orations in praise of the deceased, but with prayers for him; which prayers, it seems, were made by one who personated the deceased.

The Grecians received some of the seeds of superstitious and idolatrous worship from the Egyptians, through Cecrops, Cadmus, Danaus, and Erechtheus; and among other customs transplanted from Egypt into Greece were the solemnities used at the burial of the dead. Of these an encomium on the deceased always formed part.

From the Egyptians and Grecians, especially from the latter, the Romans received many of their laws and customs, and among them that of pronouncing funeral orations in praise of the dead. Plutarch says that "he approved of the law of the Romans, which ordered suitable praises to be given to women as well as to men after death." But from what he says in another place it appears that the old Roman law provided that funeral orations should be made only for the elder women; and therefore he says that Cæsar was the first who made one upon his own wife, though it was not then usual to take notice of younger women in that way; but by that action he gained much favour with the populace. The reason why such a law was made in favour of women, Livy tells us, was—that when the public treasury was unable to yield the sum agreed upon to buy off the Guals when besieging the city and capitol, the women gave up their jewels for the purpose; for which cause they not only received thanks, but this additional honour, that after death they as well as men should be honoured with orations.

This custom of the Romans very early obtained among the Christians. Some of their funeral orations are extant, as that of Eusebius on Constantine, those of Nazianzen on Basil and Cæsarius, and of Ambrose on Valentinian, Theodosius, and others. Gregory, the brother of Basil, made a funeral oration on Melitus bishop of Antioch. These orations were usually pronounced before the bodies of the deceased were committed to the earth, which custom has been more or less continued ever since.

FUNFKIRCHEN (i.e. *Five Churches*, Hungarian, *Pecs*), a free city of Hungary, capital of the circle of Baranya, on the declivity of Mount Mecsek, 105 miles S.S.W. of Buda. This is one of the oldest cities of Hungary, and is the seat of a bishop, and of the civil and military boards of the circle. It is well built, and consists of a single street nearly four miles in length. The cathedral is of great size, and said to be the oldest in Hungary. It has an ecclesiastical seminary, gymnasium, and other educational establishments, and had formerly a university which was much frequented. Fünfkirchen has manufactures of woollen cloths, flannels, tobacco, leather, and paper; and a considerable trade in wine, tobacco, and gall-nuts, the produce of the vicinity. There are some coal mines in the vicinity. Pop. 15,500, Hungarians, Germans, and Croatians.

FUNGI, the Mushroom order. See BOTANY, vol. v., pp. 146, 217, &c.

FUNGIBLES, in *Scots Law*, are such moveable goods and effects as may be estimated by number, weight, or measure; as corn, butter, ale, money, &c.

FUNICULAR, or ROPE-MACHINE. See MECHANICS.

FUR TRADE.

History.

THERE is perhaps no branch of commerce that has drawn forth a more daring and adventurous spirit, or given rise to a more patient and courageous endurance of personal dangers, privations, and hardships, than the fur trade, as is manifest throughout its whole history. By its means we have become accurately acquainted with nearly three-fourths of the continent of North America. The indefatigable exertions of the fur merchant, stimulated by the prospect of large gains from his hazardous pursuits, have made known numerous tribes of men and nations partially acquainted with the arts and refinements of civilized life, who otherwise might have remained many ages, or for ever, immersed in heathen darkness, and sunk in barbarity. Nor are the general advantages derived from the fur trade confined to a more accurate geographical knowledge of a vast range of country, and the extension of the arts of peace and social happiness. The adventurous fur trader has often been the precursor of the gospel missionary, and has enabled him to pursue his important labours with comparative security and success.

Whence furs were introduced.

The use of furs seems to have been introduced into Europe by the northern invaders of the Roman empire. In the sixth century the skins of sables were brought to Rome from the shores of the Arctic Ocean through the intervention of numerous parties, so that the cost to the consumer was very high. During several centuries after that time furs were not at all common in western Europe. In 1252 A.D., Marco Polo mentions, as a subject of curiosity, that he found the tents of the khan of Tartary lined with the skins of sables and ermines, which had been brought from countries far north, "from the land of darkness." In less than a century, however, from that time, the wearing of furs as a part of fashionable dress had become rather prevalent in England, since in 1337 Edward III. commanded that all persons among his subjects should be prohibited the use of furs unless they could spend L.100 per annum.

Arctic regions.

Early in the seventeenth century the shores of the Arctic seas were found tenanted by furred animals of great value; and the idea of forming a settlement was suggested by Grosseliez, a Frenchman. The suggestion was made first to his own government; but as it was coolly received, he obtained, through the English ambassador, an interview with Prince Rupert, before whom he laid his plans. The prince warmly entered into the project, and assisted in fitting out a vessel, which reached in September 1668 the river then called Nemisco, to which the adventurers gave the name Rupert in honour of the prince. After wintering there with less difficulty and suffering than they had anticipated, they returned and gave so favourable a report that Prince Rupert, the Duke of Albemarle, the Earl of Craven, Lord Ashley, and others, formed themselves into a company, and subscribed L.10,500 for the purpose of commencing a traffic in furs. A charter of incorporation was granted by Charles II. in 1670, giving to the Hudson's Bay Company full possession of "All the lands and territories upon the countries, coasts, and confines of the seas, bays, lakes, rivers, creeks, and sounds, in whatsoever latitude they shall be, that lie within the entrance of the straits, commonly called Hudson's Straits, that are not already actually possessed by or granted to any of our subjects, or possessed by the subjects of any other Christian prince or state." And the charter proceeds to grant further, that "The whole and entire trade

Hudson's Bay Company.

and traffic to and from all havens, bays, creeks, rivers, lakes, and seas into which they shall find entrance by water or land out of the territories, limits, or places aforesaid; and to and with all the natives and people inhabiting, or which shall inhabit within the territories, limits, and places aforesaid; and to and with all other nations inhabiting any the coasts adjacent to the said territories, limits, and places which are not already possessed as aforesaid, or whereof the sole liberty or privilege of trade and traffic is not granted to any other of our subjects.”

Settlements on the Rupert, Moose, Albany, Nelson, and Severn.

On Rupert's river the company immediately formed a settlement; and in 1674 stations were settled on Moose river, and a few years later on the Albany, and soon after two more on the Nelson and the Severn. By these vigorous measures the French court was awakened to a sense of its neglect, and Grosseliez, already detached from the English service, was sent out in the year 1682 to found a factory on the river Hayes, which he accomplished, and also surprised the British factory on the Nelson.

French settlements and seizures.

After this time hostilities became frequent between the French and the English settlers; yet notwithstanding immense losses sustained by the company from 1682 to 1688 (amounting to L.118,014), they were able in 1684 to pay to the shareholders a dividend of 50 per cent. Again in 1688 an equal dividend was made, and in 1689 one of 25 per cent. In 1690, without any call being made, the stock was trebled, while at the same time a dividend of 25 per cent. was paid on the increased or newly created stock. By other captures of their factories by the French in the years 1692, 1694, 1696, and 1697, the company suffered further loss to the amount of L.97,500. At the peace of Utrecht (in 1713), however, these captured factories were restored to the company, who by 1720 had again trebled their capital, with a call of only 10 per cent. on the shareholders. Now they strengthened the old forts and formed several new ones in the interior; but in 1749 a question arose in parliament concerning the rights of the company, which was decided in their favour. Again in 1782 several of their factories were taken by the French under La Perouse; still their traffic seems to have continued very lucrative until the invasion of their rights and territories by a strong rival association, designated the North-west Company, whose fierce competition caused much animosity and bloodshed. This was not only very destructive to the fur trade, but most injurious to the Indians.

North-west Company.

The North-west Company consisted of 23 partners, comprising some of the most wealthy and enterprising settlers in Canada, and employed about 2000 persons as clerks, interpreters, guides, and boatmen (voyageurs), who were stationed over the vast regions of Canada ceded in 1763 by the French to the English.

Management.

Shareholders who engaged actively in the trade were called agents, some of whom resided at the different ports established by the company in the Indian territory, and others at Quebec and Montreal, each attending to the affairs of the Company in his appointed district. These active partners met annually at Fort-William, one of their stations on Lake Superior, where they discussed matters connected with the affairs of the association, and arranged future plans. The clerks of the North-west Company were mostly young Scotchmen, of respectable families, who were willing to undergo the hardships attendant upon a residence of some years in these inhospitable regions, in order that they might thus secure the advantage of succeeding in turn to a share of the profits of the undertaking, the custom being to take from among the clerks as partners those who had acquired the experience necessary for the management of the business.

New stations.

The hunters of this company crossed the Rocky Mountains about the year 1805, and established stations on the northern head-waters of the Columbia. In 1813 they purchased Astoria on this river, which was relinquished by Mr Astor[1] of New York and his partners in consequence of the war between the United States and Great Britain.

War between Hudson's Bay Company and the North-west Company.

At length the Hudson's Bay Company, being roused by the activity of the North-west Association, exercised for the first time its chartered right to colonise, and sold in 1812 a tract of land on Lake Winnipeg and the Red River to Lord Selkirk, who introduced a considerable number of persons from Scotland. The consequence was an open war between the partizans of the rival companies. After a war of two years the Red River settlement was destroyed by the massacre of the governor, Mr Semple, and many of his associates, while the survivors were driven away. But this melancholy and barbarous state of matters was put an end to by the union of the rival companies in 1821, since which the trade has been peacefully and successfully prosecuted.

Union of the rival companies.

When the partnership of the North-west Company was about to expire in 1821, the three London representatives of the firm offered to merge their interests in those of the Hudson's Bay Company. This was agreed to, and an act of parliament was passed (1st and 2d Geo. IV., cap. 66), under which the crown grants to the Hudson's Bay Company and to the three representative partners of the North-west Company in London and Montreal a license of exclusive trade for twenty-one years in the “Indian territories;” that is, over all those tracts that might not be included in the charter given by Charles II., and also over those tracts which by mutual consent were open to the subjects of England and to those of the United States. The three North-west Company agents merged into the Hudson's Bay Company; the exclusive trading license was surrendered in 1838; and, after careful investigation on the part of the government, the crown granted on the 30th of May 1838 another license for twenty-one years of exclusive trade over the Indian and neutral territories.

Present state of Hudson's Bay Company.

The affairs of the Hudson's Bay Company are at present conducted by a governor, deputy-governor, and a committee of 7, elected by 239 proprietors, representing a capital of L.400,000. Of the 239 proprietors 55 have more than two votes. L.900 of stock must be held for six months by each voter previous to voting, except such stock be acquired by bequest or marriage; and each member of the committee must hold not less than L.1800 stock. The mode of election, oaths to be administered, government, &c., are prescribed by the charter of Charles II. already referred to.

Seat of government.

Accordingly, the Company has established at the Red River settlement a governor, council, recorder, sheriff, coroner, &c., for the proper government of the affairs of the Assiniboia, or Red River Territory, and for the careful and legal administration of justice throughout Rupert's Land. Though not enjoined by the charter of 1670, trial by jury was introduced by Sir George Simpson under the direction of the Hudson's Bay authorities in England. Crime is comparatively rare in Rupert's Land; and justice is administered under the same safeguards that exist in England.

Traffic.

The traffic of the Company in furs and peltry is regulated by a Deed Poll, dated March 26th, 1821, when the North-west Company and it united; and by another Deed Poll, dated June 6th, 1834, “for ascertaining the rights and prescribing the duties of the chief factors and the chief traders, and for conducting the trade.” The business of the Company is superintended by the twenty-five chief factors at the respective stations; and under them the twenty-eight chief traders carry on the traffic with the Indians. The clerks serve under both the factors and the traders; and the very humblest clerk, by good conduct, may rise to the chief positions in the service of the Company. The salaries of the clerks range from L.20 to L.100 per annum. Three chief factors and two chief traders are allowed to leave the country annually for one year.

---

[1] A most interesting account of the North-West Fur Company is given by Washington Irving in his ASTORIA.

Free trade in furs. The Hudson's Bay Company have no monopoly, as some suppose, of the importation of furs into England; they have to compete with the furs of the United States, of Russia, of Norway, &c.; and if other traders can undersell the Company the public have of course the benefit. Beaver and other skins are now much lower in price than formerly when so much used in the manufacture of hats; and the gradual reduction in the price of foreign furs has been chiefly brought about by the steady supply from the Hudson's Bay territories. Hence London is the most extensive fur market in the world. The fall in the prices of all furs has been very great; but as beaver constitutes the largest item in value, the reduction of profit to the Company will be seen by comparison with the prices and amount of sales. In 1839 a beaver skin was worth 27s. 6d.; in 1846, 3s. 5d. The number of skins sold in 1839 was 55,486 for L.76,312; those sold in 1846 were 45,389 for L.7856. There is also great variety in the prices of articles of similar denomination; but the Company are obliged to pay the same price to the Indians for all skins according to tariff; whether the skins are good or bad the Company must buy them. Hence the profits of the shareholders are not to be estimated by the difference in price between the cost of a skin at one of the Company's forts in the interior, and its sale price in London. The annual dividend is (1855) about 6 per cent.

The Hudson's Bay Company have now about 140 establishments besides hunting expeditions and shipping, employing 25 chief factors, 28 chief traders, 152 clerks, 1200 regular servants, besides employing in occasional labour the services of a large number of the natives; a steam vessel and five sailing vessels of from 100 to 300 tons, all armed. Their forts or stockaded positions extend from the coast of Labrador to the Pacific, and from the northern boundaries of Canada to the shores of the Arctic Ocean. At every large trading establishment there is an "Indian Hospital," from which the natives derive the greatest benefit; and several medical men are maintained by the Company at different forts. Ministers of the gospel of every denomination are encouraged and protected by the Company, and a bishop of the Church of England now presides over the diocese of Rupert's Land.

The fur trade is prosecuted in the north-western territories of the United States by an association called the North American Fur Company, of which the chief managers reside at New York. Its principal station is Michilimackinac, to which are brought all the peltries collected at the other ports of the Mississippi, Missouri, and Yellowstone rivers, and all over the vast range of country extending thence to the Rocky Mountains. This Company is admirably organized and managed: it employs steamboats for ascending the rivers, which also penetrate with ease to regions which could formerly be explored only through the most painful efforts in barges and keel-boats, or by small parties on foot or on horseback.

Fur skins imported. About 5,000,000 skins of animals applicable as furs are annually imported into Britain. The subjoined table gives the imports and exports of fur-skins in the year 1851.

Animals.	Total imported into England.	Exported.	Consumed in England.
Racoon	525,000	525,000	None.
Beaver	60,000	12,000	48,000
Chinchilla	85,000	30,000	55,000
Bear	9,500	8,000	1,500
Fisher	11,000	11,000	None.
Fox, Red	50,000	50,000	None.
... Cross	4,500	4,500	None.
... Silver	1,000	1,000	None.
... White	1,500	500	1,000
... Gray	20,000	18,000	2,000
Lynx	55,000	50,000	5,000
Marten	120,000	15,000	105,000
Minx	245,000	75,000	170,000
Musquash	1,000,000	150,000	850,000
Otter	17,500	17,500	None.
Seal, Fur	15,000	12,500	2,500
Wolf	15,000	15,000	None.
Marten, Stone and Baum	120,000	5,000	115,000
Squirrel	3,000,000	100,000	2,900,000
Fitch	65,091	28,276	36,815
Kolinkski	53,410	200	53,210
Ermine	187,104	None.	187,104
Rabbit	120,000	None.	120,000
Wolverine	1,200	1,200	None.
Skunk	1,200	1,200	None.
Sea-Otter	100	100	None.

Fur-Skinned Animals.—The northern and arctic regions abound with races of animals, which are thickly covered with fine hair or fur, and whose skins are very beautiful and valuable as articles of clothing. The animals that are captured for their fur, are:—The Russian Sable (*Mustela zibellina*).—This rich and beautiful skin has long been esteemed one of the most valuable and useful furs that have been brought to our country. About 25,000 are annually collected in the Russian territories, of which only a small number is imported into England. The fur is brown, with some gray spots on the head. The darker varieties are the most highly valued, a single skin being frequently sold for L.9, though the average value does not exceed L.2 or L.3. Naturalists are not agreed whether to consider the animal from which the skin is procured as a distinct species. Some are of opinion that the Russian sable, the stone and pine martens, as well as the Hudson's Bay sable, are but one species, on which the differences of food and climate have produced some slight variations in form and colour. To the furrier, however, the Russian sable is easily distinguishable, from the length and fulness, as well as the darker colour of the fur. The use of this choice variety is necessarily limited to the wealthy, on account of its scarcity. In the reign of Henry VIII., by a law which sought to regulate the expenses of the different classes, and to distinguish them by peculiarity of costume, the use of the sable was confined to the nobility above the rank of viscount. The Hudson's Bay Sable (*Mustela canadensis*).—The sable skins next in repute to the Russian are those imported by the Hudson's Bay Company, of which no less than 120,000 are annually brought into this country. As the natural colour of the skins is much lighter than the prevailing taste, it is the practice to dye many of them a darker colour, and the furs thus treated are scarcely inferior to the natural sable. The Baum or Pine Marten (*Mustela abietum*).—The sables imported under this name are the produce of Europe. The animal is found in extensive forests remote from the habitations of man, and preying on birds and the smaller animals. They are distinguished from the stone marten by the yellow colour of the throat; other parts of the skin are brown. When dyed, they have a similar appearance to the best sable. The Stone Marten (*Mustela saxorum*).—This marten is generally found in mountainous and stony places, though a frequent visitor to farm-yards and homesteads. It is generally distributed through most European countries. The under fur is a bluish-white, with the top hairs a dark brown. The throat of this variety is usually of a pure white, by which character it is generally distinguished. The French manufacturers excel in dyeing this fur, from which circumstance it is frequently called French sable. It is also dyed in this country, the excellent qualities of the skin adapting it to a great variety of purposes to which furs are applied. The Fisher.—There are about 11,000 of these skins annually brought to this country from North America; they are larger than the sables, and the fur is longer and fuller. The tail is long, round, and full, gradually tapering to a point, and quite black; a few years since it formed the common ornament to a national cap worn by the Jew merchants of Poland, and at that time was worth from 6s. to 9s., but its present value does not exceed 6d. to 9d. The Minx (*Mustela vison*).—There were 245,000 skins of this little animal brought to this country in 1850 from the possessions of the Hudson's Bay Company and North America. The fur resembles the sable in colour, but is considerably shorter and more glossy. It is a very durable and useful fur, and is exported in large quantities to the Continent. The Ermine (*Mustela erminea*).—This animal is similar in form and habit to the common weasel of this country; but in Siberia, Russia, and Norway, from whence the skins are imported, the little animal, during winter, becomes as white as the snowy regions it inhabits, and is esteemed as the whitest fur known, though its summer dress is a dingy brown. The tail of the skin, of which the lower half is jet black, is generally introduced as an ornament to the purely white fur. It is worn on state occasions, and in the reign of Edward III., its use was restricted to the royal family. The Fitch or Polecat (*Mustela putorius*).—These skins are produced throughout Europe, and in no place of better quality than in our own country. The ground of the fur is a rich yellow, while the top hair is a jet black. This fur is at present very little used in this country, but is much worn in America. It is very durable, but the natural smell of the fur, which is rather unpleasant, is difficult to counteract. The North American Skunk (*Mephitis americana*).—The skins known under this name are imported by the Hudson's Bay Company. The animal from which they are taken is allied to the polecat of Europe, and, from the fœtor it emits when attacked, which has been known to affect persons with sickness at 100 yards distance, has received the soubriquet of "l' Enfant du Diable." It has a soft black fur, with two white stripes running from the head to the tail, which is short and bushy. The skins, though imported into England in small numbers, are usually re-exported to the continent of Europe. The Kolinkski (*Mustela siberica*).—The Kolinkski or Tartar sable is of a bright yellow colour, and is sometimes used for ladies' dress in its natural state, but it is more frequently dyed brown to imitate other sable, to which it bears a strong resemblance. It is remarkable for the uniformity of its colour, having no spot or difference of shade in any part of the body. The tail, which is of the same colour, is exclusively used for the best artists' pencils. The Musquash or Musk Rat (*Fiber zibethicus*).—The animal known under this name is found in great numbers in North America, frequenting swamps and rivers, and, like the beaver, building its habitations of mud with great ingenuity. Dr Richardson states, that it has three litters of young in the course of the summer, producing from three to seven at a litter. The animal has a peculiar smell, similar to that of musk; but it must not be mistaken for the animal from which the musk of commerce is procured, which is a native of Tibet. About one million skins are brought to this country annually; the fur resembles that of the beaver, and is used by hat manufacturers. The skins are also dyed by the furrier, and manufactured into many cheap and useful articles. The Nutria, or Coypou (*Myopotamus coypus*).—This rodent quadruped is an expert swimmer, and frequents the neighbourhood of water, where it lives in burrows; it is smaller than the beaver, and considerably larger than the musquash, but has a resemblance to both these animals in its natural habits, and in the qualities of its fur. Until lately this fur was very much used by hat manufacturers, and as many as 600,000 skins have been annually imported from Buenos Ayres and Chili, in which countries the animal abounds. Owing to the wars that continue to be carried on between the different states of Buenos Ayres, and the consequent withdrawal of the trappers from their accustomed occupations, the importations have fallen to 3000 skins, which are dressed and dyed as a substitute for the costly fur seal. The Hamster (*Cricetus vulgaris*).—About 100,000 of the skins of the hamster are annually collected in central Germany, where the animal abounds; it has a poor, short, and coarse fur, and is almost exclusively used for cloak linings by the Greeks; the colour of the back is a reddish-brown, the belly black, with a few light spots. The animal is about 9 inches in length, and lives under ground, forming several apartments for storing grain separate from its own hybernaculum. It is so industrious and provident, that when the peasants go "hamster nesting" in the winter, they possess themselves not only of the skin but of the valuable store of good grain, which is said frequently to exceed two bushels. The Perwitzky.—The skin of this animal is beautifully marked like tortoiseshell, and is brought from the south-eastern territories of Asiatic Russia; the fur is short, giving little warmth, and is chiefly made into cloak linings, and used by the Russians. The Beaver (*Castor americanus*).—Beaver skins are imported by the Hudson's Bay Company in less quantities than formerly; the use of the fur in our hat manufactories has greatly diminished since the introduction of silk hats, and a considerable depreciation has taken place in their value. This beautiful fur is sometimes used for articles of dress. In order to prepare the skin for this appropriation the coarse hairs are removed, and the surface is very evenly cut by an ingenious machine, somewhat similar to that used in dressing cloth. The fur thus prepared has a beautiful appearance, not unlike the costly South Sea otter, and has the advantage of lightness, with durability and cheapness. The white wool from the under part of the beaver still obtains a high price, and is largely exported to France, where it is manufactured into ladies' bonnets. There is no doubt that the beaver was formerly an inhabitant of the British Isles, and Pennant remarks that two or three waters in the principality of Wales still bear the name of Llyn yr afangc, or the Beavers' Lake. The Otter (*Lutra vulgaris, Lutra canadensis*).—The large supply of otter skins used by the Russians and Chinese is derived principally from North America. The quality of the fur is in most respects similar to the otter of the British Isles, of which there are about 500 skins collected annually. This animal has frequently been tamed, and from its extreme agility in the water, has been rendered serviceable in catching fish for the use of its owner. The American otter is much larger in size than the European, being about five feet from the nose to the tip of the tail; a smaller variety abounds in the East Indies, the fur of which is very short. The Sea Otter (*Enhydra marina*).—The sea otter has a very thick, soft, woolly fur, and is most highly prized by the Russians and Chinese, to whom most of the skins are exported. In its habits it is allied to the seal, but has never been met with in large numbers. It is found in the North Pacific, from Kamschatka to the Yellow Sea on the Asiatic coasts, and from Alaska to California on the American coast. The annual production is about 1000 skins, of which 100 are imported into this country by the Hudson's Bay Company. Seal (*Phoca*).—There are numerous varieties of these animals, some of which are found on the western coasts of Scotland, Ireland, and Wales. They frequent, in immense numbers, the coasts of Newfoundland, Greenland, and Labrador, and the importations into this country frequently exceed 500,000 in one season. The young seals of some species increase in size with great rapidity, and it is asserted by the seal fishers that they double their bulk in eight days. The greater portion are tanned and enamelled with black varnish for ladies' shoes; other descriptions are well adapted for fur, especially the seal of the South Seas and the north-west coast of America. Before they can be used as a fur, it is necessary to remove the very coarse hairs which cover a beautifully fine and silky fur. The roots of these hairs are deeply seated in the substance of the thick pelt, while the fur is strongly attached to the upper surface of the skin. By shaving the pelt to half its natural substance the roots of the coarse hairs are cut through, and they easily fall out; but the same effect is produced by a natural process of fermentation, which ensues when the skins are properly prepared and allowed to remain together. The soft curly fur of the seal is now rarely used in its natural state, but is dyed a deep Vandyke brown, and has the appearance of the richest velvet. The Fox.—Of foxes' skins brought to this country there are many varieties; the black and silver foxes (*Vulpes fulvus*, var. *argentatus*) from the arctic regions are the most valuable. Many of the skins when highly dressed are worth from 10 to 40 guineas. They are purchased for the Russian market, being highly prized in that country. The cross and red foxes (*Vulpes fulvus*) are used by the Russians, Turks, and Greeks for cloak-linings and collars. The blue and white foxes are used in this and other countries for ladies' dresses. The white foxes (*Vulpes lagopus*) are represented by arctic voyagers as exceedingly numerous, and migrating in troops over the frozen seas at the approach of the rigorous season. They are easily caught, fifteen having been taken from one trap in four hours. The Wolverine (*Gulo luscus*).—This animal, which is only met with in North America, Norway, and Sweden, is now generally considered by zoologists as identical with the glutton of old writers. It is extremely mischievous to the fur-trader, and will follow the marten-hunter's path round a line of traps extending forty or fifty miles, merely to come at the baits. The fur is generally dark nut-brown, passing, in the depth of winter, almost into black, and is chiefly used in Germany and other northern countries for cloak-linings. The Bear (*Ursus*).—There are several descriptions of bear-skins used by the furrier. The skin of the black bear of North America (*Ursus americanus*) is used in this country for military purposes, for rugs, and carriage hammercloths. In Russia it is frequently manufactured for sleigh coverings, and the skin of the cub bear is highly valued for trimmings and coat-linings. That of the grizzly bear (*Ursus ferox*) is applied to similar uses. That of the white polar bear, of which the supply is very limited, is frequently made into rugs, bordered with the black and grizzly bear skins. The fur of the brown or Isabella bear (*Ursus Isabellinus*) has frequently been very fashionable in this country, when its value has been tenfold the present price. It is still considerably used in America for various articles of ladies' dress. The Hare.—The wool or under fur of the European gray hare (*Lepus timidus*) is extensively used for manufacturing felt hats, both in Europe and America. A few of these are dressed for the purpose of being worn as a protection to the chest. The white hare of Russia and the polar regions (*Lepus glacialis*) was formerly much worn in its pure white state as a lining for ladies' cloaks, and as a substitute for the white fox, but the skin being exceedingly tender, its use for this purpose has been discontinued. The white hare is also frequently dyed; it looks exceedingly rich, but is not very durable. The Rabbit (*Lepus cuniculus*).—The English rabbit, both in its wild and domestic state, affords a very plentiful supply of useful fur. When dressed and dyed in imitation of other skins, it is manufactured into a great variety of cheap and useful articles for the middle classes. The wool has recently been manufactured into a peculiar cloth adapted for ladies' use, but by far the greater number of skins are still used for hatters' purposes. The English silver-gray rabbit was originally a breed peculiar to Lincolnshire, where great attention was paid to it; but warrens have since been formed in various parts of the country. Skins of this variety are continually exported to China and Russia, where they are much esteemed and command a comparatively high price. The Hudson's Bay rabbit is beautiful in the length and texture of its fur, but the skin is so fragile, and the fur so liable to fall off with slight wear, that it has little value as an article of dress. The white Polish rabbit is a breed peculiar to that country; its skin is often made into linings for ladies' cloaks, and being the cheapest and most useful fur for that purpose, the animal is imported in great numbers. The Squirrel (*Sciurus vulgaris*).—This attractive little animal abounds in most countries, especially in Siberia and the north of Europe. It is from the Russian dominions that we derive our principal supply of the skins of this agile creature, which exceeds in number that of any of the fur-producing animals. It is said that 15,000,000 are every year captured in Russia, our supply from thence exceeding 3,000,000 annually. The fur of the squirrel, of which there are several varieties, is light, warm, and durable; some of the lighter colours are dyed in imitation of sable. The colour of the Siberian squirrels varies from a pearl gray to a dark blue gray; the under parts, which are white, are frequently cut out and made into cloak-linings, remarkable for their lightness: the tails are manufactured into boas for foreign markets; they are also extensively used in the manufacture of artists' pencils. The Chinchilla (*Chinchilla lanigera*).—There are two chief varieties of chinchilla, the produce of South America: those from Lima are short in the fur, and inferior in quality to those from Buenos Ayres and Arica; the colour is a silvery gray, Arica producing the darkest and best-coloured skins. The general appearance of the animal places it between the squirrel and the rabbit: in its natural abodes it has the agility of the former, and resembles the rabbit in living in holes and burrows. The extreme softness and delicacy of the fur adapt it only for ladies' use. Though much admired and frequently worn in this country, it is more extensively consumed in France, Germany, and Russia. The Racoon (*Procyon lotor*).—The racoon is an inhabitant of North America: the skins are imported into this country in immense numbers; but meeting with no demand for our home trade, are exported by merchants who purchase them at the periodical sales. They are used throughout Germany and Russia for lining shubes and coats, and, being of a durable nature and moderate in price, are esteemed among the most useful furs. The Common Badger (*Meles vulgaris*); American Badger (*Meles labradoria*).—The skin of the European badger, from the wiry nature of its hair, is generally used for the manufacture of superior kinds of shaving brushes; but the skins exported from North America have a soft, fine fur, which renders them suitable for many purposes for which the larger furs are used. The Cat.—In Holland the cat (*Felis domesticus*) is bred for its fur; it is fed on fish, and carefully tended until the fur arrives at its greatest perfection; large numbers are also collected in England and many other countries. The wild cat (*Felis catus*) is much larger and longer in its fur, and is met with in extensive forests, particularly in Hungary; the colour is brownish-gray, mottled, and spotted with black. The softness and durability of the fur render it very suitable for cloak-linings, and it is also made into wrappers for open carriages and railway travelling. The Canada Lynx (*Felis canadensis*); Lynx Cat (*Felis rufa*).—The fur of the lynx is long, soft, of a grayish colour, and sometimes, as in the Norway lynx, covered with brown spots; the belly is white, silky, and not unfrequently spotted with black. The change of fashion has for some time discarded it from this country; but it is dyed, prepared, and exported in considerable quantities for the American market, where it is much valued and admired. It is generally used for cloaks, linings, and facings, for which purposes it is very appropriate, being exceedingly soft and light.

PRESERVATION OF FURS.

The fur of most animals is in its greatest perfection at the approach of winter, and before the animal has attained its greatest age. It is the object of the furrier, by dyeing the inferior skins, to imitate the more perfect specimens. Some difficulty has attended this process, as the nature of the skin will admit of the dyes being used only in a cold state; but the method which has been practised in Paris and London has been so far successful, that the permanence of the colour in the dyed sable is frequently found of equal durability to that of skins of the natural colour. Considerable excellence has been attained also in dyeing rabbit and inferior furs of those colours which are more suitable to the prevailing taste.

The first process of the fur dresser is to prepare the skins from the raw state, and render them fit for ornamental dress. In this country, the usual practice is to trample them in closed tubs with a little salt butter, turning them over and over for several hours. By this means the skins are made into soft and pliable leather. The next process is to rub them on the flesh side over a blunt iron in order to remove loose pieces of integuments, and to reduce the substance, after which it is necessary to cleanse the fur and skin completely from the grease. For this purpose it is again trampled with sawdust—usually that from mahogany—which being beaten out and repeated several times, conduces to render the fur glossy and clean, and to fit it for the cutter to fashion into any shape that may be necessary.

Furs are subject to injury by several species of moths, whose instincts lead them to deposit their eggs at the roots of the fine hair of animals. Linnæus mentions five species that prey upon cloth and furs, of which *Tinea pellionella*, *T. vestionella*, and *T. tapetzella* are the most destructive. No sooner is the worm hatched than it eats its way through the fur, and continues increasingly destructive until it arrives at its full growth, and forms itself a silken covering, from which in a short time it again emerges a perfect moth. Another cause of the decay of furs is the moisture to which they are frequently exposed; the delicate structure of the fine underfur cannot be preserved when any dampness is allowed to remain in the skin. This fact is well known to the leather manufacturer, who, having wetted his skins, allows them to remain in a damp cellar for a few days for the purpose of removing the hair, which is pulled out with the greatest facility after remaining only one week in a moist condition. It follows from these observations that to preserve furs it is necessary to keep them dry, and to protect them from moths; if exposed to damp or rain, they must be dried at a moderate distance from the fire; and when put by for the summer should be combed and beaten with a small cane, and very carefully secured in a dry brown paper or box into which moths cannot enter. During the summer they should be examined once a month, to be again beaten and aired, if the situation in which they have been placed be at all damp. With these precautions, the most valuable furs may be preserved uninjured for many years.

MANUFACTURING OF FUR FOR FELTING PURPOSES.

In the manufacturing of furs for the making of hats, the principal kinds of skins used are the hare, rabbit, beaver, and nutria. All these kinds of skins, in the northern parts of Europe, as well as in America, are divided by furriers into two distinct sorts, namely, the *seasoned* and *unseasoned* skins. The former are those which are taken off the animal in winter, when the fur is at its full growth, and in the highest state of perfection as to fineness; the latter are those obtained in spring, summer, and autumn. The fur in the unseasoned skins is short, coarse, and hairy, and is generally not worth more than a third of the value of furs cut off the best-seasoned skins. The mode of manufacturing both descriptions is, however, the same; of which we shall now endeavour to give a brief account.

Hare-Skins.—The first mechanical operation performed on the hare-skin is to open it with a knife down between the middle of the forelegs, taking great care that the skin be not torn; for there is a considerable waste of the fur if this precaution be not attended to. The skin must now be rubbed with what is called a *rake*, which resembles a common dinner knife, with teeth like a saw. This is used for the purpose of clearing away all impurities and dried blood which may happen to be upon the skin. This cleaning is of very great importance; for the smallest particle of dirt or blood will greatly injure the fur for felting purposes. The operation requires to be carefully and judiciously performed for another reason. If the workman be not attentive, he will tear up, along with the bloody and dirty parts, a considerable part of the good and clean fur, and thus great loss will be incurred.

Hare-skins, after being thus opened and cleaned, must be damped on the pelt side with a little water, and placed under a heavy weight, pelt to pelt, to press them, so that all ridges and inequalities in the pelt may be removed. The skins are now fit for what is called *shearing.* Their outsides are all covered over with a kind of hair, which possesses no felting properties whatever; and this must be taken off with hand shears. These are of two kinds; the one the common shears used for clipping the wool off sheep; the other kind resembles the cutting shears of tailors, only the bowl is made equally large on both sides, for the admission of all the fingers. Some furriers prefer one kind of shears and some another. Those like tailors' shears make the neatest work when skilfully used; but the other requires less time for their management. The shearing of the skins forms a very important part of their manufacture; for if one cuts too far down, he will seriously destroy both quality and quantity of the fur, as well as disfigure its appearance. On this account many furriers confine a part of their work-people to this branch of the business alone; for the greater part of the profits of a master depends upon the manner in which this shearing process is performed.

After a hare-skin has been submitted to the process of shearing, it presents an appearance altogether different from what it did before. A novice would not know it to be the same skin. Previously, it was of a uniform brown colour; now, it is down the whole of the back of a most beautiful jet black, which gradually becomes fainter as it approaches the sides of the skin. After it undergoes the process of *rounding*, which consists in taking off all the irregular or angular pieces of skin, and making the pelt smooth and even, it is then fit for the cutting-board.

The cutting-boards of furriers are made of the willow tree, and are commonly about twenty inches wide, and from two to three feet broad. They ought to be moistened with water at short intervals, when used, to make the wood soft, and prevent the edge of the cutting-knife from being taken off too soon. These knives are sometimes made of common sheet-iron, but more frequently of steel, which are to be preferred to the former, on account of keeping their edge longer, and being much lighter for the hand. A fine edge will not cut the fur off the skins; it must be a rough edge, which is obtained from rubbing the knife about every two or three minutes upon a piece of common freestone, of not too fine a grain. These knives are from five to six inches in length and three in breadth, and resemble in some measure those knives used by grocers for the cutting up of cheeses. The skins are all, before cutting, split down the middle of the back into halves. The cutting then commences at the head or cheeks of the skin, and always in the line of direction in which the fur lies. The cutting-knife is run quickly backward and forward against the first joint of the fingers across the skin; whilst at every two or three strokes the hand must be lifted up, to gather in the fur that has been cut, and preserve it in as fleecy a form as possible. Care must be taken against *chopping* the fur; because, when this takes place, the felting principle in all furs is considerably weakened, and in some entirely destroyed.

An important point in the getting up of furs for sale is, to keep them in as unbroken or fleecy consistency as possible. This, abstractly considered, is of no consequence to their felting power; but the practice of the trade as to this matter has arisen from a desire to keep the different kinds of fur from being mixed with one another, and thereby in some degree to prevent adulteration. From this cause the above mode of cutting the hare-skin has been long since much improved by the use of instruments made of tin, against which the cutting-knives run, and which are so contrived as to gather in the whole fur off the largest skin with as much ease as the fur of a half skin could be gathered by the hand when the knife runs against the fingers. This simple invention preserves all the most valuable parts of the skin in one lump or fleece, and enables the workman to sort the fur with more ease and readiness than before.

Rabbit-Skins.—The rabbit-skin is cut in precisely the same manner as that of the hare, only there is a considerable difference in the mode of dressing or preparing the former. The rabbit-skin is covered over on the pelt side with large quantities of grease or fat, from which the hare-skin is comparatively free. This must be removed when the rabbit-skin is first opened. The knife used in opening the skin must be pressed down upon that part of the pelt where the fatty substance is, till it gets beneath the cuticle on which it rests, when the whole of the greasy matter may be removed, and a little whitening rubbed on the spot. If this operation be not well attended to, the grease will get mixed with the fur, and damage it considerably. The rabbit, like the hare skin, is covered over with hair upon the top of the fur; but this hair cannot be taken off by shearing, as in the case of the former, but must be removed by *pulling* it out. This is done with a short knife about three inches long, which is held so as to grasp the hair between the thumb and it, which is secured from injury by having a piece of buckskin leather placed over it. The hand of the workman ought to fall lightly upon the skin, otherwise the hair will be cut and the fur pulled out also, which will deteriorate its quality and diminish its quantity very considerably.

Beaver-Skins.—The skin of the beaver is manufactured in the same way as that of the rabbit. The fat, however, in the former is much greater in quantity and more firmly imbedded in the pelt than in the latter; and of course greater care and trouble are required to remove it. Fuller's earth mixed with whitening is used to imbibe the fatty particles. The pulling the outside hair off is of great importance. The cutting of the beaver has been for some years performed by machines; the thickness and regularity in the pelt affording facilities for this mode of operation, which the generality of other skins do not.

The fur of the beaver is sorted into three or four different kinds; but that which is cut off the cheek of the skin bears the highest price. White beaver is comparatively scarce, and is much esteemed for fine drab hats.

Nutria-Skins.—These are dressed like rabbit-skins, only the hair on the outside of the skins is much stronger than in the rabbit, and requires a sharper knife and greater strength to remove it. Nutria-skins are full of fat; and before they are submitted to the pulling process, they must be well washed with soap and boiling water. The skin is laid with the pelt downwards, and well scrubbed on the fur side with a brush, till the grease is entirely removed. They must then be well washed in cold spring water, which is extracted from amongst the fur by a piece of wood made for the purpose. After this they are placed before a stove or hot fire to dry, and are then fit to go through the other manufacturing processes.

Both the beaver and nutria furs, before they are used for hat purposes, must go through the operation of *blowing.* This is done for the purpose of clearing them of those short black hairs which remain amongst the fur after it is separated from the pelt. A blowing machine consists principally of a cylinder, into which the fur is placed; and by means of a fly-wheel, situated within it, the stuff is thrown up, and the hairs, by reason of their greater specific gravity, fall to the bottom, and leave all the fine fur upon the top. Hare and rabbit furs are also partially used in a blown state for the nap or outside covering of hats.

Though the hare, rabbit, beaver, and nutria furs are the staple articles of hat manufacture, yet there are other furs occasionally used in their stead, or in conjunction with them. These are the furs of the otter, the seal, musquash, and the mole. The otter is fully as fine as the beaver itself; but the principal objection hatters have to its use is, that it does not retain a good black, but acquires a brown or coppery shade. The seal is not so fine as the otter. It finishes dull upon a hat, and, in consequence, is not much used at present. Musquash is a useful fur. The mole is the only skin known to furriers which for felting purposes needs no preparatory dressing before cutting. Its fur is alike fine throughout. But notwithstanding its fineness, it is so very short as to prevent its being extensively used in the hat manufacture.

Within the last century many attempts have been made to apply machinery to the cutting of the various kinds of fur, but, with the exception of the beaver fur, these attempts have hitherto been but partially successful. The great difficulties in the way of machinery for cutting purposes are, the unevenness on the surface, and the inequalities in the thickness of the pelt in different skins. The smallest particles of the fleshy part of the skin getting among the fur will injure it; so much so, that a piece of pelt not larger than a pin's head will destroy the finest hat. This circumstance has greatly increased the difficulty of bringing machinery to bear upon the fur trade. There are, however, at this moment some machines employed in the cutting of hare and rabbit skins in England; but until they undergo numerous improvements, they are not likely, from the obstacles above adverted to, to realize the expectations of gain at first entertained by those employing them, either in the saving of labour, or in the superior manner in which the fur is manufactured.

Many experiments have also been made to dispense with the usual processes of cutting the different kinds of fur with knives, by applying chemical substances to the pelts, so as to loosen the roots of the fur, and make it leave the pelt upon a slight application of force. Lime has often been tried for this purpose, by using it in the same manner as skinners do in the management of sheep-skins. Some furriers have also tried a partial state of putrefaction; but this, as well as the lime preparation, has proved abortive. The fur obtained off different kinds of skins by such means looks in every respect as well to the eye as if it had been manufactured in the usual manner; but the felting principle is by all such means entirely destroyed.

Carroted Fur.—Sulphuric acid has the property of increasing the felting power of most kinds of fur. When this is applied the fur is called *carroted*, from the colour which the acid gives it. The most common kind of fur submitted to this process is that belonging to the rabbit-skin; and it is generally employed in small quantities for the manufacture of all fine stuff hats. Carroted coney wool is made in the following manner:—Mix one part of sulphuric acid with two parts of pure spring water, in a dish of stoneware; then take and wet the rabbit-skin with a brush all over, making the liquid penetrate as near to the bottom of the fur as possible; care being used, in this process, not to touch the skin with the fingers, lest they be burned, but with a piece of iron hoop doubled so as to resemble a pair of tongs. When the skins are thus wet, they must be placed over a very hot fire to dry; but they must not be placed too near, lest they take fire, which they are very apt to do from the application of the acid. Instead of drying them before the fire in this manner, some run a hatter's finishing iron, heated to a certain degree, over the skins, and allow them to dry gradually in the sun. This is found to be a very good plan. When the skins are dry they ought to be gently beaten with a rod, and moistened on the pelt side with water, previous to their being put under the pressing stone. They are then cut in the usual manner. Skins prepared in this way attract a great quantity of moisture from the atmosphere; and carroted fur always feels to the hand as if partially wet.

The fur off the rabbit-skin improves in its felting capabilities by being kept a moderate length of time after being taken off the skin; but hare fur does not. Great attention ought to be paid by hat manufacturers, who keep considerable stocks of fur on hand, as to the place in which they are deposited. If it be too damp, they will rot; if too dry, they will diminish in weight; therefore a moderately dry and cool place ought to be chosen. The great enemy to all furs is the common moth. This destroys the felting principle. Whenever the slightest appearance in the fur indicates the secure lodgment of this little creature, it ought immediately to be used; or, if this cannot be done, it should be taken out of the paper bags, and broken all over with a small switch rod, or, what will answer the purpose still better, a hatter's bow. The same rules apply to the keeping of skins in good condition as to fur. The situation ought to be cool, dry, and well aired. They will seldom keep longer than twelve or eighteen months without running great risk of suffering injury from the moth or black beetle. Too many ought not to be heaped together, and particularly if they be rabbit-skins, because the fat or grease about these skins will get heated, run amongst the fur, and become of such an acrid nature as to corrode the very pelt itself. It was formerly the practice to keep hare and rabbit skins a long time, under the idea that the fur upon them will increase in length from the moisture left in the pelt. This is an entirely erroneous opinion. Any one who will make the experiment will find that the amount of fur obtained off any given quantity of skins is much greater in weight when manufactured immediately after they are taken off the animal, than after having been kept for six or twelve months.

The qualities of all kinds of furs differ very considerably, from climate and other local circumstances. The best rabbit fur, used for the manufacture of the finest London hats, is commonly considered as the produce of the east coast of England, particularly from Lincolnshire to Berwick inclusively. The rabbit fur is always stronger in the felting principle when got off rabbits bred on the sea-coast, than in those found in inland places, however favourable in other respects these places may be for the rearing of the animals. The skins along the tract of coast already mentioned seem all of the same size and quality. North of Berwick the rabbit-skin becomes smaller, and the fur weaker and shorter; and the further north, along the coast, the more inferior it is found. Hare fur in Great Britain is superior, for hat purposes, to any in the world.

FURCA, a Latin word signifying properly a *fork*, was also used among the ancient Romans to denote an instrument of punishment, composed of two pieces of timber joined together in the form of the letter V inverted. This was placed on the offender's neck, while his hands were fastened to the two ends; and in this way he was compelled to carry about the badge of his disgrace wherever he went. Slaves were frequently punished thus. Sometimes the infliction of the scourge was superadded. The furca was also employed in the ancient mode of capital punishment, when the criminal was fastened to it and scourged to death. The *patibulum*, another instrument used for the same purpose, or as a gibbet, appears to have been in the form of the Greek letter Π.

FURCHÉ, in *Heraldry*, an epithet of a cross forked at the ends.

FUREEDPORE, a town of Hindustan, the principal place of the British district of the same name, under the jurisdiction of the lieutenant-governor of Bengal, on the right or S.W. bank of the Ganges. The district of Fureedpore, which is also called Dacca Jelalpore, is bounded N. by the British district Mymensing, E. by Dacca, S. by Backergunge, W. by Jessore and Pubna. Area, 2052 square miles. It is altogether an alluvial tract, being intersected by the Ganges, and also by several feeders and offsets of that river. Pop. 855,000, which gives 416 to a square mile. The district was included in the grant of the Dewanny made by the emperor Shah Alum to the East India Company in 1765. The town is 115 miles N.E. of Calcutta, in Lat. 23. 36., Long. 89. 50. (E. T.)

FURETIÈRE, ANTOINE, author of the *Dictionnaire Universel de la Langue Française*, was born at Paris in 1620. He first studied law, and practised for a time as an advocate, but finally entered the church, and became abbé of Chalivoy, and prior of Chuines. In his leisure moments he devoted himself to letters, and in virtue of his satires in prose and verse was admitted a member of the French Academy in 1662. That learned body had long promised to the world a complete dictionary of the French tongue. Furetière had already planned and executed a work of a similar nature which he was on the point of publishing when the Academy interfered, alleging that he had borrowed from their stores, and that they had the exclusive privilege of publishing such a work as that in question. After much bitter recrimination on both sides, Furetière was expelled from the academy. For this act of cruel injustice he took a very severe revenge in his satire entitled *Couches de l'Académie*. His *Dictionnaire Universel* was published in Holland two years after his death, which happened in 1688. It was afterwards revised and improved by Basnage, who published his edition of it in 1701, and again in 1725. This work enjoyed a deservedly high reputation till the appearance of the *Dictionnaire de Trevoux*, which indeed is based on that of Furetière. Furetière's other works, consisting chiefly of satires and fables, do not possess any very great literary merit.

FURIES (in Latin *Furiæ* or *Diræ*, in Greek *Erinnyes* or *Eumenides*), in *Ancient Mythology*, the deities whose business it was to punish in Hades the crimes committed upon earth. The name "Eumenides," applied to these goddesses by the Greeks, signifies the "kindly" or "propitious" deities. Like the term "Semnæ," or "venerable," it was euphemistically employed by the Athenians, who feared to call these terrible beings by their real names. Though the proper office of the Eumenides was to punish murder, perjury, disrespect to old age, and other such crimes, they were sometimes invested with very different functions. Thus, in Æschylus' play, *The Eumenides*, they appear not only as the instruments of wrath and vengeance against the matricide Orestes, but also as promising victory and every sort of prosperity to the people of Athens. In this play, too, they are described as being far more numerous than accorded with the received traditions. They seem to have numbered at least fifteen, whereas common accounts make them only three, and give their names Alecto, Tisiphone, and Megæra.

In friezes and sculptures the furies are depicted as dark beings, with serpents intertwined among their hair, blood dripping from their eyes, and holding scourges or torches in their hands. The sacrifices offered to them consisted generally of black sheep. No wine was offered at their sacrifices, but only libations of oil, honey, and water, called "nepalia." Everything relating to these deities is fully discussed in the second essay appended to Müller's edition of the *Eumenides* of Æschylus.

FURLONG, an English measure of length, equal to one-eighth of a mile, 220 yards, or 660 feet.

FURLOUGH, in military language, a license granted by a commanding officer to an officer or to a private to be absent from duty for a certain time.

FURNACE,

Definition and uses.

A GENERAL name for those contrivances used in the arts and in chemistry, by which an extraordinary degree of heat is generated, much more intense than what obtains in our ordinary fire-places. These are of very extensive use, particularly where metals and minerals are the subjects of manufacture or of examination, such substances requiring a very powerful heat for their reduction, calcination, or fusion. Hence the various kinds of furnaces which occur in the manufacture of iron, steel, brass, copper, zinc, &c. in smelting, casting, and forging the metal, and in numerous other processes connected with the formation of it. In other cases, such as glass-works, potteries, and various others, it is in general not so much a very intense heat that is wanted, as a steady temperature, and the fire of such magnitude as will keep a large body of material in fusion, and at a very equable state for working. Another large and extensive class of furnaces, and one which is becoming every day of more and more importance, is that applied to the generation of steam in the boilers of steam-engines; and here also it is not so much an intense heat which is necessary, as a very large quantity for a rapid production of the elastic fluid. The construction of furnaces therefore forms an interesting and very important branch of practical mechanics. We shall endeavour at present to explain the general principles of their construction, and describe a few of those most generally in use; and further information will be found in treating of the different arts, manufactures, and processes where the furnaces are chiefly employed.

General principles.

In regard to the general principles on which the operation of furnaces depends, the exact nature of the process of combustion is, we believe, hardly yet settled among chemical philosophers; and experiments are wanting to determine many points which might be practically useful. It was thought, for example, by Sir Humphry Davy, that by a vivid and rapid combustion of our fuel, a much greater quantity of heat would be generated than by a slow and languid action; and this theory, were it consistent with fact, would often be of great importance where economy of fuel is the object. Be this, however, as it may, it is certain that, in our ordinary furnaces, whatever be the fuel, the grand supporter of combustion is the atmospheric air, or rather the oxygen, which forms one of its constituent parts; and it is the combination of this aerial element with the solid mass of the combustible material in the furnace, which somehow or other, not well understood, produces all the heat that we obtain.

Supply of air.

To provide, therefore, a supply of this vital principle is the first object in the construction of every furnace. It appears, from some experiments on the products of combustion made by our celebrated chemist Dr Thomson of Glasgow, that for every pound weight of good caking coal consumed in a furnace, there will be required at least 150 cubic feet of common air; and adding fifty more for what cannot be rendered effective, we may allow at least 200 cubic feet to each pound of coal; and this may give us some idea of the vast quantity of air which must be required for many of the large furnaces and fires which are frequently used. In many of the furnaces, for instance, for the boilers of our steam-vessels, the consumpt of coal is more than twenty cwt. each hour; and by the above calculation this will require 7400 cubic feet of air per minute.

Draught by chimney.

It may seem at first no easy matter to supply so large a stream, and to make it pass regularly through the fire; yet this is done in the simplest manner, by means of the chimney, on the principle of the ascensional power of heated air; and few examples occur in practical mechanics of so simple, beautiful, and highly useful an application of a general principle. Air, like every other substance, is expanded by heat, and this in a remarkable degree, owing to the feeble aggregation of its elementary parts. With every degree of Fahrenheit, from the temperature of freezing to that of boiling mercury, or 680°, it expands the 488th part of its bulk. This is according to the accurate experiments of Messrs Petit and Dulong; and these philosophers also found the important law to obtain exactly within the above range of the thermometer, that equal increments of heat produced equal increments of expansion. Hence with a heat of 488°, which is far surpassed in our fires, the volume of the air is doubled; but with every such expansion the air becomes in proportion specifically lighter, and ascends by its buoyancy through the colder and of course denser medium around it. The fire therefore heating the air above it, this ascends, and the chimney forming a tube or perpendicular shaft, either directly above the fire-place, or in communication with it, the heated air fills it, and forms a rarefied column standing in the midst of the ordinary medium. The external columns, therefore, pressing on all sides into the partial vacuity, must rush in below where there is a free communication through the fire: thus a constant draught of air sets in towards the fire and up the chimney; and by this means the combustion in the furnace is kept up. It is exactly what takes place on a great scale over the globe itself, by the sun heating excessively the regions under the line; and this causing everywhere a current of heated air upwards, draws continually a current of cold air from the regions on each side of the tropics; and it is this which produces the phenomenon of the trade-winds, the opposite currents coming into collision under the equator, and destroying each other's effect as to north or south, while the rotation of the earth gives the whole an apparent motion nearly due east. The chimney then is the most essential part of every furnace, and its use is not only to create a draught of heated air, but to receive and discharge the smoke and other aerial products which arise from the combustion. In ordinary fire-places, where only a very moderate degree of heat is wanted to heat our apartments comfortably, the chimney is left open below, immediately above the fire-place, for the convenience of getting fuel or cooking utensils put on. In that case only a very small portion of the air which ascends up the chimney passes through the fire, namely, that which ascends from under the grating, and perhaps a little in the front. The greater proportion ascends above the fire-place, and this mixing with the heated air, cools it, and moderates the draught, which would otherwise become too great. In furnaces, however, where all the heat is required which can be produced, a different arrangement becomes necessary. The fire-place in these must be closed on all sides, and

Essential parts.

Grating.

every access to the air excluded, excepting below, where the fuel rests on an open grating, consisting of iron bars laid parallel to each other, and at such distances apart as will retain the fuel, while the air is admitted through them, and the ashes and other refuse drop down into the ash-pit below. Hence arises the same general construction in every furnace; and, however they may vary in particular forms and dimensions, each contains a *fire-place*, *grating*, *ash-pit*, and *chimney*. It is very essential, particularly where an intense temperature is wanted, that the fire-place should be surrounded with substances of a very slow conducting power for heat, otherwise this would be soon dissipated in the surrounding atmosphere, and no high degree of temperature attained. Clay is found very useful for this purpose in small furnaces intended for experiments; and the effect is most strikingly exhibited if we try the action of a fire-place of sheet iron: the heat is extremely feeble, and is observed dissipating itself on all sides; but if we line it with an inch thickness of clay or pounded charcoal, a very intense heat may then be generated. In large furnaces there is no material so useful for this purpose as brick, which is not only a slow conductor, but can be made to withstand very intense heats. The magnitude of the fire must evidently be determined by the size of the grating; for, however large the fire-place be made, or great the quantity of fuel in it, unless the grating is such as will admit a sufficiency of air, the combustion will not proceed. In large fires, therefore, intended to generate a great quantity of heat, such as those for steam-engine boilers, the grates must be made large in proportion. In fires, again, where it is not so much quantity as an intense temperature, the grate may be quite small, as the temperature will depend chiefly on the power of the draught. Most of the operations of the brass-founder, and of gold and silver-smiths, are performed with furnaces of which the grate does not exceed two feet in area. It may be reckoned generally, that for every ten pounds of coal consumed in an hour, there should be a square foot of area in the grating. The spaces between the bars should be about three eighths or half an inch. The bars themselves should be loose, and made to rest on two cross bars, one at each end, so that they can be taken out and renewed at pleasure. In that case they are made about an inch thick, and with a swell in the middle for greater strength. They are seldom made more than two feet or two and a half feet in length, one or more of such lengths being used if required.

Power of the draught.

But the grating itself, though it will admit it, will not determine any air to enter and pass through the fire. This is done by the draught in the chimney; and according as this is more or less powerful, the fire will burn with greater or less force. It is of the first importance, therefore, to determine what are the circumstances in the form and dimensions of the chimney on which the effect of this draught depends, and by which it may be regulated to our purposes. It is evident, in the first place, that the warmer the air is in the chimney, the greater will be its buoyant force, and the more powerful, therefore, the draught upwards. Every means, therefore, should be taken to preserve the heat in the chimney; and hence the great advantage in dwelling-houses of conducting the vents as much as possible through the interior walls, which are not exposed to the cooling effects of the atmosphere, or of wind and rain, and also carrying them up in a mass together, by which each protects the other from the cold; secondly, the interior of the chimney should be as straight, smooth, and regular as possible, that the current of air may traverse it with the least possible degree of impediment. There should be no projections, nor any sudden inequalities in width, which are sure to create eddies, and obstruct the progress of the air. Hence even the cylindrical form of a chimney will be found to improve the draught, because it presents a larger area than a square in proportion to its circumference, and therefore presents less obstruction. A decided improvement has lately been introduced in the construction of domestic chimneys, by the use of cylindrical cans of fire-brick, about a foot long, and built in, one above the other, to the top of the chimney. These are glazed inside, and present on the whole a very smooth and equal bore for the heated air. The cylindrical form of a chimney also presents externally less extent of cooling surface than the square. Still there are facilities of construction in the square form which give them an advantage. But whether circular or square, as the air becomes necessarily rather cooler at the top of the chimney than the bottom, and therefore denser, hence the chimney should have a slight degree of taper in proportion to this.

Height of chimney.

But of all the circumstances affecting the draught of furnaces, that which has the most powerful influence is the height of the chimney. The reason of this will be evident, if we consider that the mechanical force producing the draught is nothing else than the superior weight of the external air over that within the chimney. The latter forms a column expanded by heat, and having thus lost part of the air which it would have contained had it been at the same temperature with the external air. The external column, therefore, presses on the internal with a force exactly equal to this difference, and which is evidently proportional to the height of the chimney. For suppose we had a chimney fifteen feet high, and the air within it heated to 488°, then one half of the air originally in the chimney will be expelled. The column of fifteen feet would now, if the tube were extended, occupy thirty feet. This fifteen feet, therefore, of the expanded air, being taken out of the scale of the internal column, it is evident that the external air will now act with a preponderating force exactly equal, or with such a pressure as will be due to a column of the expanded air fifteen feet high, which is just equal to a column of the ordinary air seven and a half feet high. But suppose the chimney is thirty feet high under the same circumstances, then the column of expanded air expelled by the heat will be thirty feet high, and the preponderating column of ordinary air fifteen feet, just double of the former, in proportion to the double altitude, and so of every other height; and hence we deduce an important rule, that the *height* of the preponderating part of the column of air, by which the draught is produced in the chimney, is in every case *proportional to the height of the chimney itself;* and it is easy, from what has been stated, to form a calculation of this height in every case. Let H be the height of the chimney, n the number of degrees by which the internal air is heated beyond the external, taking of course the average heat of the top and bottom of the chimney, or any other rule for giving a true average from top to bottom, then $H + \frac{nH}{488}$ will be the height of the internal column when expanded by the heat, and $\frac{nH}{488}$ the height of the preponderating part of the external column, supposing it to have the density of the internal. But suppose it to be of the ordinary density, it will be $\frac{nH}{488 + n}$.

These principles then being established, it is easy now to calculate the velocity with which the external air will rush into the chimney; and this is the most important point to arrive at, as it is this which must determine the rate of supply, and whether it will be more or less than what is calculated on. This velocity, then, or V, according to the well-known formula, will be each second eight times the square root of the height of the preponderating part of the column; and as this height is proportional to that of the chimney itself, hence the rule that *the velocity is proportional to the square root of the height of the chimney.* Taking then the above expression for the height of the preponderating part of the column, we have the velocity of the external air rushing into the chimney $V = 8\sqrt{\frac{nH}{480+n}}$. But in passing along the sides of the chimney, the air, particularly with great velocities, encounters considerable obstruction; and for this, and for what may arise from inequalities or other causes, we may allow 6 instead of 8 for the co-efficient in the above formula; this gives $V = 6\sqrt{\frac{nH}{480+n}}$. The air is also greatly obstructed at the grating, and in passing through the interstices of the fuel; but this is supposed to be allowed for by giving the grating an enlarged capacity on this account, so that it may have the same facility in passing through the fire as it has in the chimney. This source of obstruction therefore need not be taken into account.

The above simple formula will be found to agree very nearly with facts; and we have been thus particular in deducing it from well-known and established principles, as rules and calculations have been given on this subject by different authors, the results of which differ considerably from each other. In cases of this nature, it is really superfluous to enter into all the refinements of calculation; there are in actual practice so many anomalies and deranging circumstances, that the only rules of any utility are those which embody simply, but with accuracy, the leading principles involved in the action; more complicated formulæ, even though rigidly exact, instead of guiding, serve often rather to deter the practical engineer from any calculation at all. In an ingenious paper on this subject, by an eminent mathematician, in the *Quarterly Journal of Science*, rigorous formulæ are given for the above calculations; but they are more complex, and the accuracy of some parts may be doubted. The rarefaction of the air by heat, for example, is calculated by a rule which makes it, for 1500°, to be expanded upwards of twenty times its natural volume; whereas, by Petit and Du Long's experiments, it would not exceed $4\frac{1}{4}$ times. Let us now take an example. Suppose we have a chimney thirty feet in height, and the average temperature of the air in it 300° above the external atmosphere, What will be the velocity with which the external air will enter the chimney? Here $H = 30$ $n = 300$, therefore $V = 6\sqrt{\frac{9000}{788}}$, or about 20 feet per second. Hence a chimney at this height, and one foot square, ought to supply 1200 feet per minute; and, from what we have seen, this would be sufficient to consume six pounds of coal per hour; and by enlarging the area of the chimney it would be adapted to a larger fire. But suppose it is raised to 100 feet, the velocity being in every case as the square root of the height, this would give the ratio of $5\frac{1}{2}$ to 10, or 37 feet per second, and a supply, with a one-foot chimney, of 2220 feet a minute. This shows how slowly the effect of raising the chimney proceeds. It requires the height to be raised four times to double the effect, and nine times to triple it; and this explains the great effect, comparatively, which is often produced by chimneys of moderate height judiciously constructed.

In this manner it is easy to calculate the effect of different heights and areas of chimneys, and proportion our dimensions to the nature of the fire to be used. In the above calculations it must be kept in view that the velocity referred to is always the velocity of the external air entering under the fire. The velocity in the chimney itself may be often very different; and by not attending to this distinction, serious mistakes may be committed. The formula for this velocity is simpler, being $V = 6\sqrt{\frac{nH}{480}}$, and in the above case it is twenty-five in place of twenty, and the supply 1500 feet in place of 1200.

Blast-furnace.

In the smelting of iron, and other uses, where a more intense temperature is required than can be produced by the natural draught of a chimney, it is necessary to resort to artificial means for increasing the effect; and this gives rise to the *blast-furnace*, where the draught is produced by the action of bellows or blowing cylinders throwing by mechanical force a violent current of air into the fire. The same object has recently been attained in a very convenient manner by means of fanners, which was originally proposed, we believe, by Desaguliers in the *Philosophical Transactions*, under the name of the centrifugal wheel, for the purpose of ventilating hospitals, ships, &c., and was a few years ago revived and successfully adapted to the blast-furnace by Messrs Carmichael, engineers, Dundee, and is now employed, not only for smelting, but instead of the bellows in the smith's forge, eight or ten forges being in some manufactories all supplied from one fan-wheel.

Description of furnaces.

We shall now describe a few of the furnaces most generally in use. The first is the common air-furnace used chiefly for melting the metals. In this, the metal being placed in a crucible, is set in the heart of the fire, and the heat is communicated directly from the materials in combustion, of which charcoal or coke is the most powerful. The draft is produced by a chimney of proper capacity and height, and the heat generated is retained by a building of brick. The most perfect form of air-furnace of this description would be to have the chimney ascending right above the fire-grate, and to be nearly of the same capacity. In that case, the draft would operate with the most powerful effect. But in practice it is found more convenient to have the use of the space immediately above the fire-place for getting in and out the crucibles and the metal. The chimney is therefore set to a side, and the draft directed into it by a sloping vent, or even by a level flue, the height of the chimney making up for any deficiency in the direct course of the heated air. Plate CCLXIV. fig. 1, shows a furnace of this description, being a section and side elevation. A shows the fire-place or body of the furnace, with a smelting-pot or crucible on its stand. The stand is often omitted, but is useful in raising the crucible above the grate, so as to allow the bottom of it to receive the full heat of the fire. B is the sloping flue, terminating in the chimney C, and D is the cover or door for closing the opening when the crucible is set. The angle E at the top of the inclined vent serves for setting a crucible to heat when necessary. *a* is the grate, and F the ash-pit opening through the outer wall, or into a cellar below, which serves to prevent the cold air rushing in from injuring the workmen. *d* is the damper. Fig. 2 is a plan of the same furnace, showing the furnace-bars, &c.

Common air-furnace.

Fig. 3 is a section of another air-furnace, with a horizontal flue above the fire-place. Fig. 4 is a section of a brass-founder's melting-furnace, which is found to answer the purpose extremely well. The body of the furnace is circular, composed of three courses of bricks formed to the arch, as shown in the plan, fig. 5. At the top and bottom, and at the two intermediate joints of the bricks, the whole is bound with hoops like a barrel, forming a very strong and durable construction. The flue is horizontal, and of small capacity compared with the fire-place. Above all there is an iron plate, with a flanch in front, holding the brick-work together, and an iron cover, *a*, shutting the opening. A is the ash-pit; B the pavement on the floor of the workshop.

Reverberatory furnaces.

The next sort of air-furnace is what is termed the reverberatory furnace. In this the metal is acted on, not by the heat generated among the combustible materials in the heart of the fire, but by the action of the flame and the heated air striking against it as it ascends up the chimney. The fuel best suited for this furnace, therefore, is coal, not coke; and for the purpose of directing the current, the space above the fire-place is arched over, and a horizontal or slightly descending flue is extended from this space to about three or four times the length of the fire-place, until it terminates in the bottom of the chimney. In this flue the metal is placed, and the flame and heated air striking against the top of the arch above the fire-place, is from thence reflected with full force against the metal, and from this sort of reverberation which takes place the furnace takes its name. From this action, and from the flame heating the interior of the chimney, the effect of this furnace is very powerful; and it is most extensively used in the iron manufacture.

At Pl. CCLXIV. figs. 6, 7, and 8, are represented a plan and sections of one of these reverberatory furnaces. A is the fire-place with the arch above; B the descending flue; C the chimney; *d* the damper; E the ash-pit; F is an opening for introducing the metal or other substance to be acted on, which is laid on the inclined hearth at B, where the flame, reverberating from the top of the arch, strikes with full force. If the substance is intended to be melted, it runs down, and can be taken out at the opening G.

At fig. 9 is a view of another reverberatory furnace, contrived by Dr Black. The hearth or bottom of the flue B here is horizontal. Immediately above the fire-place there is an arched cover, H, of iron, from the top of which an arch of brick-work is extended all the way to the chimney, in which the flame reverberates down upon the hearth. There is only one opening, F, for the introduction of the metal. This furnace may be used with advantage for roasting various substances, such as the ores of metals, for the purpose of expelling their volatile matter. It may also be employed for the cupellation of metals, the door, F, being a little opened for admitting atmospheric air.

Furnace by Mushet.

A furnace of great power was constructed and employed by Mr Mushet, in his numerous and valuable experiments on iron and steel, and was found very convenient for such operations. It is represented at Plate CCLXV. figs. 1, 2. 3. Fig. 1 is the section of an assay or melting and annealing furnace, and also a small reverberatory furnace for fusing in very high heats with the flame of pit-coal.

The assay-furnace is cased in cast iron, with a flanch projecting inward the breadth of a brick, and about half an inch more, which serves instead of bearers for the bars (see fig. 2 at D). Upon this flanch the brick-work is reared. It ought to be of good fire-bricks on the bed. The furnace is nine inches square; total height twenty-seven inches. From the top of the flanch to the bottom of the flue the interval is eighteen inches; the flue is four inches high; the height above is five inches; flue seven inches long, and keeps opening into the chimney, as may be seen at fig. 3 at E. If the chimney is under twenty-five feet in height, a larger flue is requisite; and if beyond thirty-five feet, a smaller flue will throw the heat more regularly through the furnace. In general, however, more harm ensues from too small than too large a flue. G is the floor-line, and also represents the edge of a grate which covers the ash-pit, which is better seen on the ground-plan, fig. 3, and in fig. 2 at H. This grate lies nine inches from the bars, having an open space for the admission of air. It projects twenty-four inches outwards, and serves the operator to stand upon.

I I, in figs. 1 and 2, is the ash-pit. In fig. 3, which is a ground-plan of the chimney and furnaces, C is the annealing or cementing furnace, in which the crucibles are annealed or baked to a bright red heat, and from thence introduced, along with the matter to be operated upon, into the assay-furnace. It also serves instead of a cementing furnace, being easily made to produce a heat of 100° of Wedgewood. It may be made of any size, from nine to fourteen inches square; a nine-inch chimney being sufficiently wide to the extent of an eighteen-inch furnace.

The chimney to each furnace is carried up five feet perpendicular; they then gradually incline to the centre opening, which they enter about twelve feet above the flues. L, L, L are dampers. From the grates of this assay-furnace to the top of the chimney the interval is thirty-three feet.

This furnace has melted 400 grains of malleable iron in ten minutes, and half a pound from lumps in forty minutes. If the materials to be operated upon are prepared with judgment, any experiment to the extent of half a pound of matter may be performed in half an hour, and less quantities in much less time. When approaching to its highest heat, a Stourbridge clay crucible (which drops in 168° of Wedgewood) will disappear in fifteen minutes from the time that it is put in. The first five bring it to 140° of Wedgewood, at which cast iron boils. Steel boils in it at 160°, and malleable iron boils in it at 170° to 172° of Wedgewood. It is probable, however, that the advantages of this furnace do not result from the height of the chimney (which is not so great), or from the size of its opening. More, it is likely, depends upon the flue, the opening of the grate bars, the size of the fuel, and particularly the feeding of the fire.

Muffle furnaces.

In many cases it is desirable to heat the articles of manufacture without exposing them to the smoke or dust arising from the fire or flame. This gives rise to a variety of furnaces variously adapted to the purpose; a kitchen oven is a furnace of this description; also the brass-founder's hot-plate or lacquering furnace; the furnaces used by enamellers; and all the different kinds known by the name of muffle-furnaces, in which a close vessel or cavity is formed above the fire-place, or in the draft of heated air from it, with a door opening externally, and by this the articles to be heated are introduced. Plate CCLXV. fig. 4, represents a very convenient lacquering furnace or hot-plate for brass-founders. It stands at some distance from the wall of the apartment. The fire-place is immediately under the plate, and the flue carried horizontally into the chimney. Above the plate there is a square cover or box of tin plate, open below, which can be let down over the plate, and encloses the articles as in an oven.

Figs. 5 and 6 represent a convenient furnace for enamellers. It is merely a common air-furnace, similar to those already described, with a close vessel of earthenware placed over the fire-place, the latter being swelled out to allow the heated air to ascend on each side of the vessel. A is the fire-place; B the ash-pit; *a* the grate; C the vessel with its door; D the chimney; and *d* the damper; the other parts to be understood. This furnace may also be used for assaying metals by cupellation.

Figs. 7, 8, and 9, represent a muffle-furnace for producing very intense degrees of heat, and which was employed by Pott, and afterwards by D'Arcet, in their experiments on earths and stones exposed to a continued and violent heat. The fire-place or body of the furnace, B B, is in the form of an oblong coffer, swelling out in the middle. A shows the hole for the muffle; and the dome or upper part of the furnace is shown in D D, with a large door C, for introducing the fuel; *g* is the grate, *s* the ash-pit; and the other parts will be understood.

For an account of the glass-house furnaces, and those in the potteries and other manufactories, we must refer to the respective articles in this work.

Steam boiler furnace.

In regard to furnaces for steam-boilers, the object of these, as already mentioned, is to produce rapidly a large quantity of heat for the generation of the steam. For this purpose the fire-place and grate are of great extent, and the flame and heated air, after striking the bottom of the boiler, is conveyed in flues along the bottom, and then round and round the sides, so as to deliver the whole of the heat, or as much of it as possible, to the water, before it ascends into the chimney. Figs. 8, 9, 10, Plate CCLXVI. represent a furnace and boiler of this description. A is the fire-place; B, B, the grate bars; C, C, the boiler; D, D, D, the flues running under and around the boiler, and terminating in the chimney, E. For a more particular account, we must refer to the article STEAM-ENGINE.

In all these furnaces, and particularly those for steam-engines, a very important object has often been attempted, namely, a consumption of the immense volumes of smoke occasioned by the large fires which must be kept up for their use. For an account of these, see SMOKE and STEAM-ENGINE.

Figs. 11, 12, 13, and 14, represent the forms of fire-tongs found useful in the operations connected with furnaces.

Chemical furnaces.

Furnaces are of very extensive use in the numerous processes of chemistry, and are variously constructed, according to the notion of the chemist, the uses required, or the means within his reach. They may be divided into three kinds; crucible-furnaces, wind-furnaces, and blast-furnaces. The first are used with charcoal, or, in the larger ones, with charcoal mixed with coke. The draft for the supply of air is obtained from the mere height of the crucible, or by the addition of a funnel pipe. In the wind-furnaces, the draft is obtained by connecting them with the chimney of the laboratory, and therefore more powerful, and better adapted for various uses. In the blast-furnace, again, the air is supplied by bellows; and furnaces of this kind are capable of producing the most intense degree of heat required. The crucible-furnaces are thus described by Professor Faraday, in his well-known work on Chemical Manipulation.

An exceedingly useful furnace, either in a large or small laboratory, may be made out of a black-lead or earthen crucible. The proper crucibles for this purpose are known by the name of *blue pots*, and may be had of almost every size less than the height of twenty-two inches, and of twelve or fourteen inches diameter in the top. They are made of clay and plumbago mixed, and are easily cut by a saw, rasp, or file. The price of one which will make a very good furnace for small operations is about six shillings.

One of these vessels, of the height of twelve inches, and seven inches in width at the top within (Plate CCLXVI. fig 1), will make a very useful furnace for the igniting of a small crucible, heating a tube, or distilling with large glass retorts at moderate temperatures, or with smaller glass or earthen retorts at higher temperatures. It is first, in the course of preparation, necessary to have certain round holes pierced in it. These are easily made; a gimlet, bradawl, or other small instrument, is to be used to penetrate the sides; and the small apertures thus produced are to be enlarged with a rat's-tail and round rasp, and ultimately finished with a half-round rasp, which will make them of the size required. Four of these holes are to be placed at equal distances from each other, and about two inches from the bottom of the pot. They may be one and a fourth or one and a half inch in diameter. A second ring of holes, five or six in number, is to be made half way between the top and bottom of the pot, and a third row of five or six within two inches of the top. These holes should be rather smaller than the four lower ones.

The pot should now be bound round with iron or copper wire, to hold it together when it cracks, and a handle made to it of iron wire.

A small round grate of cast iron is only wanting to render this furnace complete for many operations; and several of these grates of different sizes should be ready at hand to drop in, and fit at different heights, as may be required. The part below the grate then forms the ash-pit, and the part above forms the body of the furnace. For the purpose of regulating the fire, if this requires to be diminished, the air-holes can be closed with stoppers made of soft brick or old blue pots; and, to increase the temperature, the body of the furnace itself may be enlarged by setting on the top of it a portion of an old pot, as in fig. 2, cut off so as to form a ring, several of which may be added as occasion requires; and they increase considerably the draft as well as the capacity of the furnace. Another simple method of increasing the power of these furnaces is to set on the top a piece of straight funnel pipe, as at fig. 3, two feet long, four inches diameter, opening out below like a funnel, till it is about eight inches diameter, with a wooden handle for the convenience of taking off or putting on. These simple furnaces are very powerful, and are capable, without difficulty, of raising a crucible two and a half inches in diameter to a white heat. In fact, all the ignitings and heatings which belong to the analysis of siliceous and other minerals have long been made in furnaces of this kind at the Royal Institution.

If the funnel-pipe in one of these crucible furnaces be connected with any chimney or flue in the laboratory, which is easily done by kneeing the pipe at the top, and having two or three short pieces to fit in for adjusting it to different lengths, as at fig. 4, its power is greatly increased, and in fact it becomes a wind furnace. The funnel termination at the bottom should be lined with fire-clay, and have an opening for the introduction of fuel, to be closed by a stopper when the fire is in order; or a still better arrangement is to continue the furnace upwards by a deep ring with the feeding apertures in it, as at fig. 5.

On the same principle with the crucible-furnace is a small portable furnace contrived by Mr Knight, and represented at Plate CCLXVII. fig. 1, and consisting of a cylinder of sheet-iron lined with an earthy composition. A B is the fire-place; B C the ash-pit, closed on all sides excepting at the register door, D, where air is admitted; E is an opening for fuel; F a recess for the neck of a retort. Fig. 2 is a funnel top for the furnace, with a pipe above extending by other lengths into the chimney. Fig. 3 is a sand-bath, which can be used in place of the dome, with a pipe rising up from it.

Dr Black's portable furnace.

On the same principle is the well-known portable furnace of Dr Black, represented at fig. 4, Plate CCLXVII, which is the most complete of the kind which has yet been contrived. It is made of sheet iron, formed into an elliptic shape for the purpose of getting a chimney separate from the body of the fire-place, and is carefully lined with clay well tempered. A B is the fire-place; B C the ash-pit; E a sliding door for the admission of fuel; D another door for the same purpose, and also for the introduction of a muffle. Fig. 5 is a cover, and fig. 6 a sand-bath. F is the chimney, which is lengthened by pipes, and connected with the chimney of the house.

On the same general principle of the wind-furnace is the general laboratory or table-furnace, which, being of considerable magnitude, is fixed in the laboratory, and forms one of the most important and useful pieces of apparatus which the chemist employs. From the extreme facility which, if conveniently arranged, it gives to every operation, its use is partly domestic, partly chemical;

for it has to warm and air the place, occasionally to heat water, as well as to supply the means of raising a crucible to ignition, or of affording a high temperature to flasks through the agency of a sand-bath.

These objects are best obtained by those furnaces which are built with a table top. The fire-place itself is constructed of brick-work with iron front and fittings; and the flue being carried horizontally for three or four feet, is afterwards carried off to and connected with the main flue existing in the wall. The fire-place and horizontal flue are covered with a large plate of cast iron, of from two to three feet in width. This is formed in the middle, over the heated part, into sand-baths; a round moveable one over the fire itself, and a long fixed one over the flue. The sand-baths supply every gradation of heat, from dull redness, if required, down to a temperature of 100° or lower; whilst on each side of them exists a level surface, which answers every purpose of an ordinary table, and supplies extraordinary facilities to experiments going on in the sand-bath or furnace. Nor are these advantages gained by any serious sacrifice of heating power in the furnace itself; for it is easy so to construct it as to make its ordinary combustion not more rapid than that of a common fire, and yet, by closing the fire-door and opening the ash-pit, to obtain a heat that will readily melt gold, silver, or cast iron.

A furnace like this is best placed in the middle, or towards one end of the laboratory, independent of the wall; for then it most effectually warms the air of the place, and there is working room all round it. The flue may then either descend and be carried off for a short distance under ground, or it may be connected by a funnel pipe with the upright draught chimney. But if more convenient, either as occupying less of the room of a small laboratory, or for other reasons, it may be placed with advantage against one side; and where the laboratory is made out of a room previously built, the best situation is generally against the fire-place, and the flue of the furnace is then easily connected with the chimney previously existing. When a furnace of this kind stands against the wall, it is frequently advantageous to construct a wooden hood over the sand-bath, to receive the fumes evolved during the digestions and solutions made upon it, and conduct them away to the chimney.

Being in constant requisition as a table, a furnace of this kind should be about thirty-four or thirty-five inches in height; its other dimensions, and even its form, must depend upon the space that can be allotted for it; and the following is a more particular description of the one in the laboratory of the Royal Institution, constructed under the direction of Mr Brande. It is represented at fig. 7, Pl. CCLXVII., and in section at fig. 8 through the line AB. It has the brick-work fifty-two inches in length and thirty-eight in width; the iron plate, including sand-bath, being fifty-seven inches by forty-two. Others have been constructed, the plates of which are only forty inches by twenty-seven. The principal part of this furnace is necessarily of brick-work, only the top plate, with the backs and the front, being of iron. The front is a curved iron plate, having two apertures closed by iron doors, one belonging to the fire-place, and the other to the ash-pit. It is thirty-four inches high and fourteen inches wide. The ash-hole door moves over the flooring beneath; the bottom of the fire-place door is twenty-two inches from the ground, and the door itself is eight and a half inches by seven. This front is guarded within, at the part which encloses the fire, by a strong cast-iron plate, having an opening through it, corresponding to the door of the fire-place. It has clamps attached to it, which, when the furnace is built up, are enclosed in the brick-work. In the setting or building of the furnace, two lateral brick walls are raised on each side the front plate, and a back wall at such a distance from it as to leave space for the ash-hole and fire-place. These walls are lined with Welsh lumps where they form the fire-chamber. Two iron bars are inserted in the course of the work, to support the loose grate bars in the usual manner, the grate being raised nineteen inches from the ground. The side walls are continued until of the height of the front, and are carried backward from the front until in two parallel lines, so as to afford support for the iron plate which is to cover the whole. The back wall of the fire-place is not raised so high as the side walls by six inches and a half, the interval which is left between it and the bottom of the sand-bath being the commencement of the flue or throat of the furnace. In this way the fire-place, which is fourteen inches from back to front, and nine inches wide, is formed, and also the two sides of the portion of the horizontal flue which belongs to the furnace, and is intended to heat the larger sand-bath. The bottom of this part of the flue may be made of brick-work, resting upon bearers laid on the two side walls; or it may be a plate of cast iron, resting upon a ledge of the brick-work on each side, and on the top of the wall which forms the back of the fire-place. When such an arrangement is adopted, the plate must not be built into the brick-work, but suffered to lie on the ledges, which are to be made flat and true for the purpose; for, if attached to the walls, it will by alternate expansion and contraction disturb and throw them down. The ends of the side walls, forming as it were the back of the furnace, may be finished either by being carried to the wall against which the furnace is built, or enclosed by a piece of connecting brick-work, to make the whole square and complete; or a warm air cupboard may be built in the cavity beneath the flue, and the door made to occupy the opening between the walls. Occasionally the flue may be required to descend there, and pass some distance under ground. These joints should be arranged and prepared before the plate constituting the top of the furnace is put on to the brick-work, so that when the plate with its sand-baths are in their places, they may complete the portion of the horizontal flue by forming its upper side.

The size of this plate is the first thing to be considered, and having been determined upon from a consideration of the situation to be occupied by the furnace, and the places of the sand-bath also having been arranged, the brick-work must then be carried up, so as to correspond with these determinations, and with the plate itself, which in the mean time is to be cast. The sand-bath and the plate are to be formed in separate pieces. The bath over the fire is best of a circular form, and of such diameter, that when lifted out of its place, it may leave an aperture in the plate equal in width to the upper part of the fire-place beneath; so that a still or cast-iron pot, or a set of rings, may be put into its place over the fire. The other sand-bath must be of such a form as to correspond with the shape and size of the flue beneath. These vessels are to be of cast iron, about three tenths of an inch thick; their depth is to be two and a half inches or three inches, and they are to be cast with flanches, so as to act in the corresponding depressions of the plate, that the level of the junctions may be uniform. This will be understood from the accompanying sections of the furnace, see fig. 8, given through the line A B of the view. It is essential that these sand-baths be of such dimensions as to fit very loosely into the apertures in the plate, a space of the eighth of an inch or more being left all round them when cold, as shown in the section, otherwise, when heated, they will expand so much as entirely to fill the apertures, and even break the plate. The plate itself should be half an inch thick.

When the plate and its sand-baths are prepared, and the brick-work is ready, the furnace is finished by laying the plate on the brick-work, with a bed of mortar intervening. If the walls are thin, or any peculiarity in their arrangement occasions weakness, they should be bound together, within by cranks built into the work, and without by iron bands. The alternate changes of temperature from high to low and low to high, to which the furnace is constantly subject, renders it liable to mechanical injury, in a degree much surpassing that which would occur to a similar piece of brick-work always retained nearly at one temperature.

The sand-baths which have been described are liable to an accident that has induced some chemists to substitute others made of wrought iron. When first heated, they frequently, indeed generally, crack from the unequal expansion in different parts; and the plate itself is subject to the same accident. If constructed of wrought iron, this effect is not produced; but then, after being used some time, they warp into very irregular and inconvenient forms, especially if made of thin metal; whilst, on the contrary, those of cast iron, when cracked, are rarely injured for the uses to which they are to be applied, and seldom suffer further change.

These baths should have washed sea-sand put into them. It is heavy, and occasions no dust when moved; whilst, on the contrary, unwashed and bad sand contains much dirt, and occasions great injury in experimenting. A piece of straightened iron hoop, about twelve inches in length, should lie on the furnace, as an accompaniment to the baths, being a sort of coarse spatula with which to move away the sand.

The circular sand-bath is frequently replaced by a set of concentric rings, or a cast-iron pot, see fig. 9. The rings are convenient for leaving an aperture over the fire of larger dimension, according as a larger or smaller number are used at once; and being levelled at the edges, fit accurately into each other, without any risk of becoming fixed by expansion. The external one, like the sand-baths, should be made smaller than the depression in the furnace plate in which it rests. The iron pots are of various sizes, and adapted to the furnace by means of the rings. A red heat is easily obtained in them for sublimation.

In cases where a greater heat is required than can be obtained by the table furnace, or any of the portable furnaces already described, other wind furnaces may be constructed by proportioning the size of the chimney to that of the furnace, much surpassing these in the intensity of heat produced; but in these and other cases it is better to have recourse at once to the *blast-furnace*, the operations being more manageable and expeditious, the heat greater, and the consumption of fuel smaller. By a little contrivance, one of the crucible furnaces before described is easily converted into a blast-furnace, and a very high temperature for small vessels obtained. This is done by closing the holes of the ash-pit with the stoppers, except one, and applying to that the nozzle of a pair of double-hand bellows, from which a draft is to be urged, and the furnace aided at the same time by the piece of upright funnel pipe; the fuel is to be charcoal.

A very powerful blast-furnace on a small scale has been contrived by Mr Aikin; it is represented at fig. 10, and is all made out of broken pots. The lower piece, A, is the bottom of one of these pots, cut off so low as only to leave a cavity of about an inch deep, and ground smooth above and below. The outside diameter over the top is five and a half inches. The middle piece or fire-place, B, is a larger portion of a similar pot, with a cavity about six inches deep, and measuring seven and a half inches over the top, outside diameter, and perforated with six blast-holes at the bottom. These two pots are all that are essentially necessary to the furnace for most operations; but when it is wished to heap up fuel above the top of a crucible contained, and especially to protect the eyes from the intolerable glare of the fire when in full height, an upper pot, C, is added, of the same dimensions as the middle one, and with a large opening in the side, cut to allow the exit of the smoke and flame. It has also an iron stem with a wooden handle (an old chisel answers the purpose very well), for removing it occasionally. The bellows, which are double, D, are firmly fixed by a little contrivance, which will take off and on, to a heavy stool, as represented in the plate; and their handle should be lengthened so as to make them work easier to the hand. To increase their force on particular occasions, a plate of lead may be firmly tied on the wood of the upper flap. The nozzle is received into a hole in the pot, A, which conducts the blast into its cavity. Hence the air passes into the fire-place, through six holes of the size of a large gimlet, drilled at equal distances through the bottom of the pot, and all converging in an inward direction, so that if prolonged, they would meet about the centre of the upper part of the fire. No luting is necessary in using this furnace, so that it may be set up and taken down immediately. Coke, or common cinders taken from the fire when the coal ceases to blaze, sifted from the dust, and broken into very small pieces, form the best fuel for higher heats. The fire may be kindled at first by a few lighted cinders and a small quantity of wood charcoal. The heat which this little furnace will afford is so intense, that its power was at first discovered accidentally by the fusion of a thick piece of cast iron. The utmost heat procured by it was 167° of Wedgewood's pyrometer, when a Hessian crucible was actually sinking down in a state of porcelaneous fusion. A steady heat of 155° or 160° may be depended on if the fire be properly managed and the bellows worked with vigour.

The following is a description of a most excellent blast-furnace, which has been in use for some years in the laboratory of the Royal Institution, and is represented at fig. 11. It is sufficiently powerful to melt pure iron in a crucible in twelve or fifteen minutes, the fire having been previously lighted. It will effect the fusion of rhodium; and even pieces of pure platinum have sunk together into one button in a crucible subjected to its heat. All kinds of crucibles, including the Cornish and the Hessian, soften, fuse, and become frothy in it; and it is the want of vessels which has hitherto put a limit to its applications. The exterior consists of a blue pot, eighteen inches in height and thirteen inches in external diameter at the top. A small blue pot of seven and a half inches internal diameter at the top had the lower part cut off so as to leave an aperture of five inches. This, when put into the larger pot, rested upon its lower external edge, the tops of the two being level. The interval between them, which gradually increased from the lower to the upper part, was filled with pulverized glass-blowers' pots, to which enough of water had been added to moisten the powder, which was pressed down by sticks, so as to make the whole a compact mass. A round grate was then dropped into the furnace, of such a size that it rested about an inch above the lower edge of the inner pot: the space beneath it, therefore, constituted the air chamber, and the part above the body of the furnace. The former was seven and a half inches from the grate to the bottom, and the latter seven and a half inches from the grate to the top. Finally, a horizontal hole, conical in form, and one and a half inch in diameter on the exterior, was cut through the outer pot, forming an opening into the air-chamber at the lower part, its use being to receive the nozzle of the bellows by which the blast was to be thrown in. The furnace being thus completed, the next object was to dry it gradually, that when used it might not be blown to pieces by confined aqueous vapour; a charcoal fire was therefore made in it, and left to burn some hours, being supplied with air only by the draught through the hole into the chamber beneath. When vapours ceased to be formed, the furnace was considered to be ready for use.

This furnace has always been used with a pair of large double bellows mounted in an iron frame, the furnace being raised upon a stool, so as to bring the aperture of the air-chamber to a level with the nozzle of the bellows. The latter has generally been inserted in the aperture; for this and similar furnaces are of such depth compared to their width, that when charged with a crucible and fuel, there is so much resistance to the passage of the air, when urged by a blast competent to create and sustain a vivid combustion, that a part returns by the side of the nozzle, if the aperture be left open. The bellows spoken of is far larger than necessary for the furnace described, and is rarely worked to one third of its power; for otherwise the heat rises so high as to destroy the crucible, and the results are lost. It is, however, at all times advisable to have an abundant command of air.

The heat produced in this furnace is such as at every violent operation to cause the production of some slag from the melting of the inner surface of the furnace itself, where the combustion has been most vivid. The slag running down the interior, collects round the edge of the grate, and should be removed with a chisel and hammer, or with an iron rod, after each operation, that the grate may be clear and free of obstruction for the next process. When in the course of time the interior of the furnace is so far injured as to become thin and weak, it must be displaced, and the furnace restored to its original state by the introduction of a new inside, as before.

The fuel to be used in this furnace is coke. Its consumption is very small, considering the heat that is obtained in consequence of the short period of each operation. The superiority of the blast-furnace over the wind-furnace, in many operations for which high temperatures are required, depends upon the rapidity of its action. It is requisite to employ this furnace in the open air, or under a well-arranged vent; for an immense number of sparks, much flame, and a current of hot air, are projected during its operation, which might occasion serious mischief in a room, unless the ceiling were at a considerable height, or guarded by a metal screen.

The *fuel* to be used in furnaces is of three kinds, coal, coke, and charcoal. *Coal* is the ordinary fuel for the laboratory table furnace, or that intended to be in use every day, and to serve for fusions, roastings, and other operations, for which its temperature may be sufficient. It is very desirable that this coal should be good, and not of the kind which contains much sulphur, or an abundance of earthy matter; for the first interferes with various fusions and ignitions, and the latter renders the fire dirty and dusty, and, when the temperature is raised to a high point, causes an abundance of clinkers. On certain occasions to be hereafter distinguished, especially if the coal be sulphureous and bad, it may be necessary at times to use both coke and charcoal in the table-furnace. Coal should never be used in the blast-furnace; for, in consequence of its softening and swelling by heat, it aggregates, closes the small channels by which the air finds a passage through the fuel, and impedes the combustion.

Coke is in constant requisition. It varies in quality with the coal from which it is obtained. Such as is intended for the service of the blast-furnace should be free from sulphureous, earthy, and metallic matter. Of this kind is the Staffordshire coke, which may be obtained at various wharfs on the canals near London. It is frequently so little altered in appearance as to resemble the original coal. It burns completely away in a blast-furnace, leaving scarcely a trace of slag, so that after several successive portions have been introduced, no material quantity of refuse is produced upon the grate, nor any thing that will act seriously on the crucible as a flux.

On the contrary, if common gas-coke be used in this furnace, the oxide of iron and earthy matter which it contains is so abundant, that slag is soon produced, which flowing over the crucible, corrodes and destroys it.

The *charcoal* intended for laboratory use may be of the ordinary kind, and must not be either too large or too small. If large, the pieces should be broken down, or they will be unfit for use in the crucible furnaces, for which it is principally intended. Charcoal is a quick fuel; but burning with facility, a small quantity of it can be easily retained in a state of regular combustion; and hence, in cases where but little space intervenes between the substance to be heated and the side of the furnace, or when a small temporary fire is required in the air, it is very convenient. Where Staffordshire coke will burn, and, by means of a blast or a draught of air, will give sufficient intensity of heat, it is very superior to charcoal in duration. Occasionally a mixture of coke and charcoal is convenient, since it affords a combination possessing the qualities of permanency and freedom of combustion.

A charcoal box is almost as essential in a laboratory as one for coal, and should have its appointed place.

It must be remembered, that all operations with furnaces should be carried on in safe situations; care being taken that no danger be incurred by the ascent of sparks, flame, or hot air, by lateral vicinity to combustible bodies, or by standing on an unprotected wooden surface.

When small furnaces are placed upon tables, stools, or trays, a brick or a piece of sheet iron should be interposed, according to the mode by which the heat is likely to be communicated.

For further information on the subject of furnaces, see the articles already referred to, and others connected with particular arts where they are used. See also Lewis's *Philosophical Commerce of Arts;* Faraday's *Chemical Manipulation;* Parke's *Chemical Essays;* Aikin's *Dictionary of Chemistry;* Tredgold *on Warming and Ventilating Buildings;* Tredgold's *Account of the Steam-Engine;* Davies Gilbert, *Quarterly Journal of Science*, vol. xiii.; Watt's Patent Furnaces, *Repertory of Arts*, vol. iv. p. 226; Raley's Patent Furnaces, *Repertory of Arts*, vol. x. p. 155; Miche on Reverberatory Furnaces, in Rozier's *Journal*, vol. xxxii. p. 385; Howard's Improved Air Furnace, in Tilloch's *Philosophical Magazine*, vol. v. p. 190; Perceval's Chamber Lamp Furnace, *Repertory of Arts*, vol. iii. p. 29, and in the *Transactions of the Royal Irish Academy*, vol. iv., p. 91; Accum's Improved Universal Furnace of Dr Black, in his *System of Practical Chemistry*, vol. ii., p. 357, and in Nicholson's *Journal*, vol. vi., p. 273, 8vo. Curaudeu's new Evaporating Furnace is described in the *Annales de Chimie*, No. 149, an. xii.; and in Nicholson's *Journal*, vol. ix. For other descriptions of furnaces, see IRON-MAKING, &c. (G. B.)

FURNEAUX ISLANDS, a group of islands in Bass Strait, between Australia and Van Diemen's Land, consisting of four large and numerous smaller islands. Great Island, the principal, is about 40 miles in length by 10 in breadth; Cape Barren, Clarke's, and Preservation Islands, are the next in size. These islands are barren and unproductive, being sandy in the lower parts.

FURNES, a town of Belgium, province of W. Flanders.

26 miles W.S.W. of Bruges, on the canal from Bruges to Dunkirk, not far from the North Sea. It has a brisk trade in corn, cattle, butter, and cheese; and contains (1851) 4766 inhabitants.

FURRUCKABAD, a fortified town of Hindustan, province of Agra, and capital of the district of the same name. The town was built by a Patan colony about a hundred years ago, and is situated about a mile from the western bank of the Ganges. It contains a small citadel, and the palace of the nabob. The streets are wide, and the houses and open places are shaded with trees. It carries on an extensive trade with Cashmere and other parts of India, and derives considerable benefit from the extensive military cantonments of Futtehghur in its vicinity. Long. 79. 40., Lat. 27. 24.

The district of Furruckabad is situated for the most part in a country inclosed between the Ganges and the Jumna, and between the 27th and 28th degrees of north latitude. Area, 2122 square miles. Pop. 1,064,607; of which 936,747 are Hindus, and 127,860 Mohammedans. The latter are stated to be descendants of the Patans or Afghans, who early in the last century established themselves in the tract extending between Oude and the Punjaub. In 1749 the emperor of Delhi, marching to Furruckabad, confiscated the estates of the deceased ruler, and conferred them upon the vizier of Oude; from whom, however, they were again wrested by Ahmed Khan, brother of the former ruler. After a lapse of some years the territory appears to have reverted to the vizier of Oude, who in 1801 transferred it to the protection of the British. Upon assuming possession the East India Company effected an arrangement with the tributary nawaub, under which his claims were liquidated by an annual stipend, which is still enjoyed by his descendants. The district is represented as tranquil and prosperous. (E. T.)

FURSTENWALDE, a town in the Prussian province of Brandenburg, government of Frankfort, on the right bank of the Spree, and on the railway between Berlin and Frankfort, 28 miles E. of the former city. It has manufactures of linen and woollen goods, and about 5000 inhabitants. It was taken by the Swedes in 1631, and burned by the Imperialists in 1633.

FURTH, an important manufacturing town of Bavaria, circle of Middle Franconia, at the confluence of the Pegnitz with the Rednitz, 5 miles N.W. of Nurnberg, with which it is connected by railway. This town is chiefly indebted for its importance to the industry and perseverance of the Jews, who here enjoy privileges not accorded to them in other parts of the continent. At the beginning of the present century they composed nearly one-half of the whole population, and they now amount to about 2700. They have a college, a separate court of justice, several schools and synagogues, and two Hebrew printing establishments. The manufactures are various, including mirrors, jewellery, lacquered wares, chandeliers, spectacles, liqueurs, tobacco, leather, woollen and cotton goods, &c. A large annual fair is held here at Michaelmas, which lasts for fourteen days. In 1632 Gustavus Adolphus was defeated in the neighbourhood of this town, in attempting to carry the intrenchments of Wallenstein. Pop. (1849) 16,061.

FURTHCOMING, in *Scots Law*, is an action by which a person who has used an arrestment in the hands of his debtor's creditor may have the money or goods so arrested delivered up to him or sold in satisfaction of his claim.

FUSE, or FUZE, in *Artillery*, a small tube filled with a combustible composition, used for firing shells. This tube is cut to a length proportioned to the intended range of the shell, so that it may explode at the instant the shell touches the ground. The composition consists of nitre, sulphur, and mealed powder. A 13-inch fuze burns forty seconds. Naval service fuzes are made of gun-metal, calculated for certain ranges.

FUSEE (Lat. *fusus* a spindle), in *Clock-work*, a kind of grooved cone around which the chain or cord is wound. (See CLOCK AND WATCH WORK, vol. vii., p. 28.)

FUSELI, HENRY, an eminent painter and writer on art, was born at Zürich in Switzerland, 7th February 1741. His father was John Caspar Füssli, an artist of some note, and author of *Lives of the Helvetic Painters*. This parent destined his son for the church, and with this view sent him to the Caroline College of his native town, where he received an excellent classical education. One of his schoolmates there was Lavater, with whom he formed an intimate friendship. After taking orders in 1761, Fuseli was obliged to leave his country for a while in consequence of having aided Lavater to expose an unjust magistrate, whose family, however, was still powerful enough to make its vengeance felt. He first travelled through Germany, and then visited England, where he supported himself for some time by literary hack-work. At this time he had the good fortune to become acquainted with Sir Joshua Reynolds, to whom he showed his drawings. By Sir Joshua's advice he now devoted himself wholly to art. In 1770 he made an art-pilgrimage to Italy, where he remained till 1778, in which year he returned to England, taking Zürich on his way. He found a commission awaiting him from Alderman Boydell, who was then organizing his celebrated Shakspeare gallery. Fuseli painted a number of pieces for this patron, and about this time published an English edition of Lavater's work on physiognomy. He likewise gave Cowper some valuable assistance in preparing the translation of Homer. In 1788 Fuseli married, and soon after became an Associate of the Royal Academy. Two years later he was promoted to the full dignity of an Academician. In 1799 he exhibited a series of paintings from subjects furnished by the works of Milton, with a view to forming a Milton gallery, corresponding to Boydell's Shakspeare gallery. In that year he was appointed professor of painting to the Academy. Four years afterwards he was chosen keeper. In 1805 he brought out an edition of Pilkington's *Lives of the Painters*, which, however, did not add much to his reputation. Canova, when on his visit to England, was much taken with Fuseli's works, and on returning to Rome in 1817 caused him to be elected a member of the first class in the Academy of St Luke. Fuseli died at Putney Hill, 16th April 1825, at the advanced age of eighty-four, and was buried in the crypt of St Paul's Cathedral.

Though under any circumstances Fuseli would probably have made himself a great name in art, yet he enjoyed peculiar advantages in making his appearance at a time when English art was begining to recover from the degradation into which it had been gradually falling since the days of Rubens and Vandyke. Portrait-painting had been restored to its ancient dignity by Sir Joshua Reynolds: the great school of British landscape had been founded by Wilson and Gainsborough: but historical painting had nothing to show except a few specimens from the pencil of Reynolds, some hasty and superficial yet powerful and promising pieces by Mortimer, and the solemnly correct and tamely cold productions of West. The very qualities that were wanting in these men, Fuseli possessed in profusion. He had a daring invention, was original, fertile in resource, and ever aspiring after the highest forms of excellence. His mind was capable of grasping and realizing the loftiest conceptions, which, however, he often spoiled on the canvas by exaggerating the due proportions of the parts, and throwing his figures into attitudes of fantastic and over-strained contortion. In the treatment of his subjects, which he delighted to select from the region of the supernatural, he pitched everything upon an ideal scale, believing a certain amount of exaggeration necessary in the higher branches of historical painting. In this theory he was confirmed by the study of Michael

Angelo's works and the marble statues of the Monte Cavallo, which, when at Rome, he used often to contemplate in the evening, relieved against a murky sky or illuminated by lightning. But this idea was by him carried out to absurd extremes, not only in the forms, but also in the attitudes of his figures; and the violent and intemperate action which he often displays destroys the grand effect which many of his pieces would otherwise produce. A striking illustration of this occurs in his famous picture of "Hamlet breaking from his attendants to follow the Ghost." Hamlet, it has been said, looks as though he would burst his clothes with convulsive cramps in all his muscles. Even in pieces where calmness and simplicity are aimed at, the figures are sometimes twisted into monstrous convolutions, or twisted into the most abrupt and singular angles. This intemperance is the grand defect of nearly all Fuseli's compositions. On the other hand, however, his paintings are never either languid or cold. His figures are always full of life and earnestness, and seem to have an object in view which they follow with rigid intensity. Like Rubens he excelled in the art of setting his figures in motion. Though the lofty and terrible was his proper sphere, Fuseli had a fine perception of the ludicrous. The grotesque humour of his fairy scenes, especially those taken from the *Midsummer Night's Dream*, is in its way quite as remarkable as the poetic power of his more ambitious works. As a colourist Fuseli has but small claims to distinction. He scorned to set a palette as most artists do. He merely dashed his tints recklessly over it. Not unfrequently he used his paints in the form of a dry powder, which he rubbed up with his pencil either with oil, or with turpentine, or gold size, regardless of the quantity, and depending for accident on the general effect. This recklessness may perhaps be explained by the fact that he did not begin to paint in oil till he was twenty-five years of age. Despite these drawbacks, however, Fuseli possessed the elements of a great painter. He was an enthusiastic lover of his art, and had he enjoyed a better training, and adopted a more temperate habit of thinking, he might have taken rank with the masters of the sublime Italian school, which he so deeply admired. Fuseli's general powers of mind were great. He was a thorough master of French, Italian, English, and German, and could write in all these tongues with equal facility and vigour, though he preferred German as the vehicle of his thoughts. His writings contain perhaps the best art-criticism that English literature can show. Many interesting anecdotes of Fuseli, and his relations to contemporary artists, are given in his *Life* by John Knowles, who also edited his works in 3 vols. 8vo, London, 1831.

FUSIBLE Metal, an alloy of three parts of lead with two of tin and five of bismuth, which melts at 197° Fahr. Teaspoons made of this very fusible alloy often form part of a conjuror's apparatus.

FUSIL (Fr. from Lat. *fusus*, *fundo*), a light musket or firelock.

Fusil, in *Heraldry*, a bearing of a rhomboidal form, longer than the lozenge; so called from its shape, which resembles that of a *spindle*.

FUSILIERS, or Fusileers, a body of troops formerly armed with a fusil or light musket that might be slung over the shoulder. In former times the term was applied to infantry soldiers who bore fire-arms, as distinguished from pikemen and archers. The name is still retained in the British army, which has four regiments of fusiliers, viz., the 7th, 21st, 23d, and 87th, but their equipment does not differ from that of other regiments.

FUST (Ital. *fusto* a stalk or stem), in *Architecture*, the shaft of a column, or the part between the base and the capital.

FUST, John, a goldsmith of Mayence, in the middle of the fifteenth century, and a man not more distinguished for his riches than for his knowledge of the arts, shares with Guttemberg and Schœffer the glory of having invented printing. Guttemberg is generally considered as the first inventor of this art; and, according to some, Fust had only the merit (by no means a slight one) of supplying him with money; whilst others are of opinion that the goldsmith contributed both his funds and his industry towards the completion of the invention. But however this may be, a partnership was formed between them in 1450, and it appears that these associates practised successively three sorts of impressions: first, the *tabellary*, that is, in carved tablets or plates, like our engravings on wood; secondly, the *xylographic*, or in moveable characters of wood; and, lastly, the impression in characters cast in moulds or matrices, analogous to, if not identical with, the stereotype founding of the present day. There is reason to believe, however, that Fust, notwithstanding his acquirements, contributed but little of his own invention to the operations of the partnership contracted with Guttemberg; since the latter appears to have been the first who thought of applying to regular compositions the same mode which had been long practised at the foot of engravings for their explanation; and since Schœffer, in inventing the punch, completed the discovery, if indeed this ought not to be considered as the discovery itself. Fust, zealous in favour of all that regarded his art, was so much delighted with the invention of Schœffer that he gave the latter his daughter in marriage. The *Biblia Sacra Latina*, without date, in folio, and consisting of 637 leaves, is probably the first production of printing, and seems to have been executed between 1450 and 1455, during the partnership of Fust and Guttemberg; but some think that the impression was struck from the characters invented by Schœffer. In 1455 difficulties arose between Fust and Guttemberg, who, in consequence, separated on the 6th of November. But, in reimbursement of the sums he had advanced, Fust remained proprietor of the establishment, which he now carried on with Schœffer; and to this new partnership we are indebted for the Psalter, *Psalmorum Codex*, of 1457, the most ancient work printed with a date (reprinted in 1459 from the same characters, which also served for the re-impressions of 1490, 1502, and 1516); the *Durandi Rationale Divinorum Officiorum*, 1459; the *Constitutiones Clementis Quinti*, 1460; the celebrated *Biblia Latina* of 1462, the first Bible with a date; and the treatise *De Officiis* of Cicero. Fust and Schœffer exercised printing until 1466, when Fust went to Paris, and is thought to have died of the plague which then ravaged that city.

Fust, the goldsmith of Mayence, and the promoter of printing, has, however, been sometimes confounded with Faust the magician, whose name is associated with so many imaginary horrors. The latter, born about the commencement of the sixteenth century, was the son of a peasant of Weimar, or, as some say, of Kundling. He was educated by one of his uncles, who caused him to study theology; and, notwithstanding a strong propensity to debauchery, he completed his course, and obtained the degree of doctor. But having become disgusted with this pursuit, he cultivated medicine and astrology, and in particular applied himself to the study of magic. From this time his historians are only insipid romancers, who relate a thousand absurdities respecting him. They make him conjure up the devil himself; employ an infernal spirit named Mephistopheles, with whom he made a paction for twenty-four years; descend into hell, and travel through the celestial spheres, as well as through all the countries of this sublunary world, everywhere surrounding himself with illusions, playing mischievous pranks, having commerce with Helen the wife of Menelaus, causing Alexander the Great to appear to Charles V., and, lastly, to terminate the whole in a suitable manner, having his neck twisted by the devil at the expiration of his compact with that personage. Much more infallible than even the illustrious Mathew Laensberg, Faust yearly circulated in Germany almanacks, which, being dictated by Beelzebub, could scarcely fail to have great success. Such are the marvellous feats related by George Rodolph Widman, who published at Frankfort, in 1587, 8vo, the history of John Faust, and Christopher Wagner, his valet. This history, or rather this romance, reprinted at Berlin in 1590, and at Frankfort in 1591, re-appeared at Hamburg, 1598–1600, in three volumes 4to, with historical, physical, and moral commentaries, filled with ignorance and folly; and it was also translated into English, Dutch, and French. Adelung has honoured Faust with an article at the end of his *History of Human Follies*, where will also be found the *Conjurationes Fausti*, but without the mysterious figures which ought to have accompanied them, and by means of which the reader might easily perform the same prodigies as the magician of Weimar. The Germans, who are fond of the marvellous, have often brought upon the scene the descent of Dr Faust to the infernal regions. Of this number are the celebrated Goethe, Klinger, and J. F. Schink; whilst Trithemus, the most ancient of all, J. Manlius, Schaller, Wier, Del Rio, and even Camerarius and Gesner, have discoursed of Faust and his enchantments, of which Peter-Frederick Arpe has favoured the world with a catalogue. But, notwithstanding the testimony of these writers, many others (perhaps with reason) regard this personage as entirely imaginary, and consider his history as a romance intended merely for amusement. Some, indeed, including Conrad Durius, are disposed to think that the legend of Faust is a satire fabricated by the monks against John Fust, one of the inventors of printing, who had incurred the resentment of these cenobites by being concerned in a discovery which superseded their useful functions as copyists of manuscripts; but others have shown that this opinion is not well founded. Upon the subject of Faust, the curious reader may consult Zeltner's *Schediasma de Fausto præstigiatore ex Joanne Fausto a quibusdam ficto;* Struvius in his *Introductio in not. Rei Litterar.*, and in his *Bibl. Antiq.;* and Neumann's *Dissertatio Historica de Fausto præstigiatore*, Wittemberg, 1683, 1693, 1711, in 4to. (J. B—E.)

FUSTIAN, in *Commerce*, a kind of cotton stuff, twilled or ribbed on one side.

Fustian, in *Criticism*, an inflated or bombastical style of writing or speaking.

FUSTIC, the wood of *Morus tinctoria*, used as a yellow dye. See Dyeing, vol. viii., p. 295, &c.

FUSTUARIUM, in *Roman Antiquity*, a method of inflicting capital punishment upon any soldier guilty of theft, desertion, or similar crimes. When the accused had been found guilty, he was made to stand in front of the legion to which he belonged. One of the tribunes then touched him lightly with a stick, and all the soldiers immediately rushed upon the criminal and beat him to death with clubs (fustes). If he escaped—as he was allowed to do if he could, but which was rarely if ever possible—he was forbidden ever to return to his native country, and his nearest relatives were not allowed to receive him into their houses. This method of capital punishment continued to be enforced even under the empire. The "animadversio fustium" differed from the "fustuarium." It was a kind of corporal chastisement inflicted upon freedmen of the lower orders, and was less severe than the flogging with *flagella*, which was confined to slaves.

FUTTEHGHUR, a town of Hindustan, British district of Furruckabad, on the western bank of the Ganges, three miles from the city of Furruckabad. In the vicinity is the British military cantonment. The station is held in high estimation by the military, being healthful and abundantly supplied with provisions. Holkar, the Mahratta chief, appeared before the place in 1804, and was preparing for the assault of the fort, when the arrival of the British army under Lord Lake drove him into precipitate flight. Lat. 27. 22.; Long. 79. 41. (E. T.)

FUTTEHPOOR, a town of Hindustan, province of Agra, 24 miles from the town of that name. It was enlarged and embellished by Akbar, in honour of a celebrated saint, to whose prayers the Emperor Akbar thought that he was indebted for a son. The tomb of this saint is situated on a mountain near the town, and is still the resort of Mohammedan pilgrims. The place is inclosed with a high stone wall of great extent; but the space within appears never to have contained buildings. Futtehpoor presents at present a wide extent of ruined houses and mosques, interspersed with fields of rice and mustard, with a few tamarind trees; and nearly in the middle, on a high ridge of rocky hills, is a range of numerous palaces, serais, and other public buildings, in the best style of Mussulman architecture, with a noble mosque in good repair. Long 77. 44. E.; Lat. 27. 5. N.

FUTTEHPORE, in Hindustan, a town in the British district of the same name, on the route from Allahabad to Cawnpore. Lat. 25. 57.; Long. 80. 54. It is described as a large and thriving town, with a population (1853) of 20,864. The district, of which it is the chief place, is bounded N.E. by the Ganges, separating it from the kingdom of Oude, E. by Allahabad, S.W. by the Jumna, and N.W. by Cawnpore. Area, 1583 square miles. Pop. 679,787; of which 612,437 are Hindus, and 67,350 Mohammedans The district is described by a recent traveller (Captain Leopold Von Orlich) as a boundless garden, in which sugar-cane, indigo, cotton, poppy, wheat, barley, and many vegetables flourish. In 1801 the Vizier of Oude transferred the district to the East India Company in commutation of the subsidy which he had stipulated to pay for the defence of his territory. (E. T.)

FUTTOCKS, in a ship, the timbers raised over the keel, or the encompassing timbers which form her breadth and capacity. *Futtock plates* are iron plates crossing the sides of the top-rim perpendicularly. The dead eyes of the top-mast rigging are fitted to their upper ends, and the futtock shrouds to their lower ends.—(Dana's *Seaman's Manual.*)

FUTWA, a town of Hindustan, in the British district of Patna, under the jurisdiction of the Lieut.-Governor of Bengal, situated at the confluence of the Pompon with the Ganges, nine miles south of Patna, over which is a good bridge of brick. In 1574, when the Afghan army was retreating before Akbar, the bridge broke down, and the troops were mostly either drowned or put to the sword. It is noted for the manufacture of tablecloths and sheeting. Long. 85. 22. E.; Lat. 25. 30. N. (E. T.)

FYNE, Loch, an arm of the sea in Argyleshire, about 40 miles in length, and 5 in average breadth. See Argyleshire.

FYZABAD, a town of Hindustan, province of Oude, on the S. bank of the river Dewah or Gogra. This city is said to have owed its origin to the Nabob Sufder Jung, who in 1740 erected some temporary houses in an extensive garden at this place; and his son, Shuja Addowleh, after the battle of Buxar, made this his residence, and gave orders for erecting a palace and other public buildings. The city soon rose into importance; but Shuja having subsequently transferred his residence to Lucknow, many of the houses, which had been hastily built, fell into decay. It is still, however, a considerable city, and contains a numerous population, chiefly of the lower classes, the merchants and bankers having removed to Lucknow along with the court. Fyzabad was the residence of the two celebrated Begums, the mother and grandmother of the last-mentioned nabob. Adjoining is the ancient city of Oude or Ayodha, the capital of the great Ram, who conquered Ceylon. The city contains some handsome tombs belonging to the reigning family; and its gardens are celebrated for grapes and other fruits. It is 90 miles E. of Lucknow. Long. 82. 10. E.; Lat. 26. 46. N.

G.

G, the seventh letter and fifth consonant of our alphabet, and the third in the Hebrew, Phœnician, Chaldee, Syriac, Samaritan, Arabic, and Greek. The Hebrews call it *ghimel* or *gimel*, a camel, from its fancied resemblance to the hump on the back of that animal; and it bears the same appellation in the Samaritan, Phœnician, and Chaldee: in the Syriac it is called *gamel*, in Arabic *jim*, and in Greek *gamma*. The Greek gamma, Γ, is manifestly the ghimel, ג, of the Hebrews or Samaritans turned in the opposite direction. The early Latins used C for the Greek *gamma*, and hence C came to hold the third place in the alphabet. Diomedes (lib. ii., cap. *De Litera*) calls G a new letter. His reason is, that the Romans had not introduced it before the first Punic war, as appears from the *Columna Rostrata* erected by Duilius, in which C is everywhere found instead of G. It was Sp. Carvilius who, as we learn from Terentius Scaurus (120 A.D.), first distinguished between these two letters, and invented the figure of the G.

G, however, is found instead of C on several medals (Vaillant, *Num. Imperat.* tom. i., p. 39); and Beger produces a medal of the *Familia Ogulnia* where we find *Gar* instead of *Car*, which is the reading on those of Palin. But C is more frequently seen on medals instead of G, as *Aucustalis*, *Callæcia*, *Cartacinensis*, &c.; not that the pronunciation of these words was altered, but only that the G was unskilfully or negligently cut by the workmen; as may be seen in different inscriptions of the eastern empire, where AVC is frequently found for AUG, and so in other cases. The northern nations frequently changed the G into V or W, as in *Gallus*, *Wallus*; *Gallia*, *Wallia*, *Vallia*, &c. But it must not be supposed that the French have changed the W into G; because they wrote *Gallus* long before *Wallus* or *Wallia* was known, as appears from all the ancient Greek and Roman writers. And yet it is equally true that the French change the W of the northern nations, and V consonant, into G; as *Willielmus*, William, into *Guillaume*; *Wulphilas* into *Gulphilas*; *Vascon* into *Gascon*, and so in other cases.

The letter G is a mute, and cannot be sounded without the help of a vowel. It is formed by the reflection of the breath against the palate by the tongue, or, as Martianus Capella expresses it, G *spiritus cum palato*; so that G is a palatal letter. The modern G takes its form from that of the Latins. In English it has two sounds; one from the Greek Γ, which is hard, as before *a*, *o*, *u*, *l*, *r*; and the other soft, resembling that of *j*, as in *gesture*, *giant*. G is often hard before *i*, as *give*, &c., and sometimes before *e*, as *get*, &c. It is also hard in derivatives from words ending in *g*, as *singing*, *stronger*, &c.; and generally before *er* at the ends of words, as *finger*. G is mute before *n*, as *gnash*, *sign*. G*h* has the sound of the hard G in the beginning of a word, as *ghostly*; in the middle, and sometimes at the end, it is quite silent, as *right*, *though*. At the end of a word G*h* has often the sound of *f*, as *laugh*, *rough*, *tough*.

As a numeral, G was anciently used to denote 400; and with a dash over it thus, G̅, 40,000. As an abbreviature, G stands for *Gaius*, *Gellius*, *gens*, *genius*, &c. G. G. for *gemina*, *gessit*, *gesserunt*, &c. G. C. for *genio civitatis* or *Cæsaris*. G. L. for *Gaius libertus*, or *genius loci*. G. V. S. for *genio urbis sacrum*; G. B. for *genio bono*; and G. T. for *genio tutelari*. In music, G is the mark of the treble cleff; and from its being placed at the head, or marking the first sound in Guido's scale, the whole scale took the name of *gamut*.

GABARA, or GABBARA, in *Antiquity*, the dead bodies which the Egyptians embalmed and kept in their houses, especially those of such as had died as martyrs, or with the reputation of great piety and holiness.

GABARDINE (Span. *gabardina*, a coat with a hood and close sleeves) has been sometimes used to denote a coarse frock, or mean dress. In this sense it is used by Shakspeare in his *Tempest* and *Merchant of Venice*, and by Butler in his *Hudibras*.

GABEL (Fr. *gabelle*; Sax. *gafel* or *gafol*): a tax, impost, or duty, particularly that on salt, but afterwards applied to all other taxes.

GABIA GRANDE, a secular town of Spain, in the province and archbishopric of Granada. It contains 4000 inhabitants, and is situated on a rising ground on the left bank of the river Genil. Gabia has a public granary and several tile and gypsum kilns.

GABII, now CASTIGLIONE, in *Ancient Geography*, an old and at one time important city of Latium, on the Via Prænestina, between 12 and 13 miles from Rome. Long before the foundation of Rome, Gabii seems to have been one of the largest and most populous of the Latin cities. According to an old tradition, noticed both by Dionysius and Plutarch, Romulus and Remus are said to have been educated there. During the period of regal Rome, Gabii appears to have kept its ground against the growing power of that city, and only fell into the hands of Tarquin the Proud by a stratagem contrived by his son Sextus. On the expulsion of the Tarquins, Sextus took refuge at Gabii, and was murdered by the inhabitants in revenge for his treachery. After this period Gabii always appears in history as the ally or dependent of Rome, and gradually fell into such a state of decay as to become a proverb of desolation. In this condition it remained till the reign of Tiberius, when the fame of its cold sulphureous waters tended to revive it considerably. After the third century it disappears altogether from history. The only relic of the ancient Gabii now visible is a temple of Juno on a hill now crowned by the ruins of the mediæval fortress of Castiglione.

In the neighbourhood of Gabii were valuable and extensive quarries of an excellent building-stone, known as the "lapis Gabinus," which was largely used by the Romans. It was a hard and compact variety of the volcanic tufa found in abundance throughout the Campagna, and closely resembled the "lapis Albanus," to which, however, it was superior.

GABINIA LEX, in *Roman Antiquity*, a law proposed by the tribune Gabinius, B.C. 139, introducing the ballot in the election of magistrates.

GABION, in *Fortification*, a kind of basket of wicker-work, cylindrical in shape, generally about three feet high, open at both ends, and filled with earth. See FORTIFICATION.

GABLE (from the Celtic *gavael*), the upright triangular end of a house, from the cornice or eaves to the top.

GABLER, JEAN PHILIPPE, was a celebrated Protestant divine, to whom we are indebted for several important works, critical and exegetical, on the text of the New Testament. He was born at Frankfort-on-the-Maine, June 4, 1753. After having studied the ancient languages and their literature, as well as the philosophy of Wolf and the theology of Baumgarten, he resorted to the university of Jena. Being much dissatisfied with theology as then taught, Gabler was on the point of abandoning it altogether, when Griesbach, who was preparing for the publication of his New

Testament, and had just been appointed to a professorship at Jena, persuaded him to continue to pursue his theological studies. In 1780 he gave private lectures on theology at Gottingen, and soon got permission to open a public course. In 1783 he was nominated professor of philosophy at Dortmund, and two years after at Altdorf, where he became also deacon of the Protestant church in that town. He received the degree of D.D. in 1787, and in 1804 he became one of the professors of the faculty of Jena. Griesbach dying some years after, Gabler was appointed to fill his chair as first professor of theology; and, while still holding the rank of private, ecclesiastical, and consistorial counsellor, he died, Feb. 17, 1826.

The works which Dr Gabler has left show him to have been not only a man of consummate erudition, but a profound thinker. Rising above all prejudice, he gave expression to his ideas in the most candid and liberal manner. The principal of his works are: "*Essai d'herméneutique du Nouveau-Testament*, Altdorf, 1788; *Introduction Historico-critique au Nouveau-Testament*, Altdorf, 1789; and *Nouvel essai sur l'histoire de la création de Moïse*, Altdorf, 1795; a supplement to *L'Histoire Primative* by Eichhorn, of which he published an edition, much enhanced by a learned preface and notes. He took an active part also in the redaction of the *Journal Théologique*, Nuremberg, 1796–1811, in 16 vols.

GABRIEL SIONITA, a learned Maronite, was born near the end of the sixteenth century at Edden, a small town on Mount Lebanon. He was appointed professor of oriental languages at Rome, whence he was transferred in 1614 to Paris, in order that he might co-operate with Le Jay in the preparation and construction of his famous Polyglot. The Syriac and the Arabic texts were prepared by Sionita from copies which he made with his own hand from MSS. at Rome. The vowel points were added by himself as they still stand both in Le Jay and in the English Polyglot. His also is the Latin version which is in accordance with the punctuation of the texts. A dispute having arisen between him and Le Jay, he did not continue to superintend the Arabic and Syriac portions of the work to the end; in these Abraham Ecchel continued and completed the work. Sionita was the translator of the *Arabic Geography of Abu-Abdallah-Mohamed Edrisi* into Latin, and entitled *Geographia Nubiensis*, 4to, 1619. He published also an *Arabic Grammar*, which bore a high character in its day. He also translated the Psalms of David into Arabic; and soon after died in 1646 at Paris, where he had for some years been professor-royal of Syriac and Arabic.

GABRIEL (*i.e.*, *the mighty one of God*), the heavenly messenger who was sent to Daniel to explain the vision of the ram and the he-goat (Dan. viii.), and to communicate the prediction of the Seventy Weeks (Dan. ix.) Under the new dispensation he was employed to announce the birth of John the Baptist to his father Zechariah, and that of the Messiah to the Virgin Mary (Luke i.) Both by Jewish and Christian writers Gabriel is accounted one of the archangels, though the Scriptures affirm nothing *positively* respecting his rank.

GAD, a son of Jacob by his concubine Zilpah, and who became the progenitor of one of the twelve tribes. The Gadites were a warlike people, and at the time of the conquest of Canaan numbered 45,650 warriors. As a reward for having formed the vanguard of the army in war, they were allowed to appropriate to their exclusive use some pastoral districts beyond the Jordan. The inheritance of this tribe, called the *land of Gad*, was situated beyond the Jordan in Gilead, north of Reuben, and separated on the east from Ammon by the river Jabbok. According to 1 Chron. v. 11, the Gadites had extended their possessions on the east as far as Salkah, though the latter had been allotted by Moses to Manasseh (Deut. iii. 10, 13): a proof how difficult it is to draw a decided line of demarcation between the possessions of pastoral tribes. The territory of Gad forms a part of the present Belka (Burckhardt, *Syria*, ii. 598.)

Gad, a Jewish prophet, the domestic seer of king David, and his adviser in all matters of importance.

GADAMES, or Ghadames, an oasis S.W. of Tripoli, in the Sahara of Africa. It stands S. of the main chain of the Atlas Mountains, with a town near it, in Lat. 30. 10., Long. 90. 19. E. This important oasis contains numerous villages and a few antiquities of the Roman period, while it forms the centre of divergent routes to Tunis, Tripoli, the Oases of Ghraat, Twat, Gharglah, &c. See Tripoli.

GADARA, a city of Palestine, and by Josephus considered as the capital of Peræa, to the S.E. of the Lake of Tiberias. Pliny places it on the river Hieromax (now Yarmak). The country which took its name from Gadara—"the country of the Gadarenes"—was the eastern boundary of Galilee. At the time of its capture by Antiochus, Polybius states that it was the strongest city in those parts. It was restored by Pompey, and was the seat of one of the five sanhedrims instituted by Gabinius. This seems strange, since it was considered one of the Grecian cities, and so exempted from the jurisdiction of Archelaus, and put under the prefecture of Syria, though it had, by special grace, been granted to Herod the Great. The ruins of the ancient Gadara (now our Keis), to the south of the Yarmak, are very considerable. They are on the E. side of the Jordan valley, and about six miles S.E. by E. of the Sea of Galilee. The hot spring and baths of Gadara were celebrated in ancient times, ranking second only to those of Baiæ. These springs burst out from the foot of the mountain on which the city was built, and the baths were built over them. The temperature of the water is lower than the springs of Tiberias. The ruins of a Roman bath are still visible at the source of the springs.

GADES, Gaddis, or Gadis. See Cadiz.

GADOR, a royal town of Spain, in the province of Granada and bishopric of Almeria. It contains about 2000 inhabitants, and is situated on the bank of the river Almeria. The surrounding country produces of excellent quality all the cereals, as well as wine, silk, and oil, in abundance. The Sierra de Gador abounds with mines of various metals, especially of lead, in the working of which there are constantly employed above 10,000 hands. This Sierra is a lofty and enormous piece of marble, from which the finest species of lime is made. The marble of Gador dissolves completely in acids, without leaving the slightest residuum of sand or any other substance. It thus differs essentially from all the other limestones of Spain, but especially from that of Valencia; hence the ancient Spanish proverb is easily understood—*Donde hay yeso y cal, no hay mineral*—"where there is gypsum and lime there is no mineral," which is the fact in reference to the marble and limestone of Valencia. Hence also the immense difference between the ancient buildings of the city and the modern, the former being made with mortar formed of the pure water from the Rambla, while the moderns employ sea-sand.

GADFLY. See index to Entomology.

GAELIC LANGUAGE. See Language, Philology, &c.

GAERTNER, Joseph, an eminent botanist, who was born at Calw, in the duchy of Würtemberg, March 12, 1732. In the university of Gottingen he studied theology, law, and medicine, and attended the lectures of the celebrated Haller. Natural history was his forte, however; and the lessons of his illustrious teacher there, as well as those of Adrian Van Rogen at Leyden, rendered him still more devoted to its cultivation. After receiving his doctor's degree he travelled through Italy, France, England, and more recently Holland and England, and published several memoirs upon various subjects bearing upon marine botany and zoology. In 1768 he was appointed professor of natural history and botany at St Petersburg, where he commenced his great work, *Carpologia seu Descriptiones et Icones fructuum et seminum plantarum*, upon which his eminent reputation depends. At the end of two years he was obliged, by the severity of the climate, to leave Russia and return to his native land, where for eight years he arduously pursued his great undertaking. During his second visit to Holland and England, Sir Joseph Banks and Thunberg opened to him their valuable collections, the one from the South Seas and the other from Japan. So long as botany continues to be studied as a science, this great work will be held in high estimation. It contains the essential generic characters and particular descriptions of the fruits of 1000 genera, illustrated by figures drawn by himself. Gaertner excels in the anatomical elucidation, definition, and description of the parts of the seeds of plants. Schräber has named a genus of plants after him, *Gaertenera*. His other works are, *De fluctibus et seminibus plantarum*, Stuttgard, 1788, and Tubingen, 1791, in 2 vols. 4to.; a *Memoire sur les Mollusques*, printed in the *Transactions Philosophiques*. A notice of the life and writings of Gaertner was published by Deleuse in vol. i. of the *Annales du Musée D'Histoire Naturelle*.

GAETA, the ancient *Caieta*, a strongly fortified seaport-town of Naples, province of Terra di Lavoro, at the extremity of a peninsula forming the N.W. boundary of the gulf of Gaeta, 40 miles N.W. of Naples. The ancient town is said to have derived its name from Caieta the nurse of Æneas, who, according to Virgil and others, was buried here. The port became early an important shipping station, and Cicero describes it as being in his time "*portus celeberrimus et plenissimus navium.* The neighbourhood, too, became a favourite place of resort with the Romans, and the coast between Caieta and Formiæ, about four miles distant, was studded with numerous elegant villas. The town, however, seems to have been an inconsiderable place up to the time of Antoninus Pius, by whom it, together with the port, was much improved. After the fall of the western empire it for some time enjoyed a republican form of government, and was afterwards governed by dukes, who acknowledged the temporal supremacy of the pope. In 1435 it was taken by Alphonso V. of Aragon, and since that time it has belonged to the crown of Naples. It has sustained several remarkable sieges; in modern times may be mentioned those of 1702, 1734, and 1806. In 1815 and 1821 it held out for some time against the Austrians. The palace of the governor was for some time the residence of Pope Pius IX. after his flight from Rome in 1849. Of the ancient city the remains comprised a temple and aqueduct. The most interesting, however, is the sepulchre of L. Munatius Plancus, called *Torre di Orlando*, which stands on the highest part of the isthmus connecting the citadel with the mainland. It is of a circular form, in excellent preservation, and retains its inscription uninjured. Mola di Gaeta occupies the site of the ancient Formiæ, where Cicero had a favourite villa, and where he was put to death by order of Antony. Gaeta is surrounded by walls flanked by bastions and redoubts, and defended by a castle. It is the see of an archbishop, and has a fine cathedral, several other churches and convents, a public seminary, hospital, and foundling asylum. It has a considerable trade, and the port is one of the best in Italy. Pop. (exclusive of the garrison) about 10,000, of whom nearly three-fourths are in the suburbs.

GÆTULIA, in *Ancient Geography*, a district of Africa, bounded on the N. by Mauretania and Numidia, E. by the country of the Garamantes, S. by the basin of the Niger, and W. by the Atlantic. The Gætuli, who inhabited it, and from it took their name, are stated by Sallust to have been one of two great aboriginal races of Africa; the Libyans being the other. They originally occupied the northern sea-board of Africa, from which they were gradually driven out by the Asiatic invaders, who afterwards became known as Numidians and Mauretanians. They were a warlike race of fierce disposition, and without a settled government; and roved over the deserts, clad in skins, and living on milk and the proceeds of the chase. They engaged but little in trade, though their country yielded abundantly some valuable natural products. The shores of the Atlantic, especially, furnished in great quantities the murex, from which the famous purple dye of antiquity was obtained.

Till the Jugurthine war the Gætuli, according to Sallust, were ignorant of the Roman name. In that struggle they furnished a quota of cavalry to the armies of the Numidian king. Some of them afterwards served under Marius, and owned a kind of allegiance to Hiempsal. In the civil war large numbers of them sided with Cæsar; but in the time of Augustus conducted themselves in a manner so turbulent and disorderly, that they had to be kept in check by a powerful army.

GAFF, in nautical language, a spar to which the head of a fore-and-aft sail is bent. *Gaff-topsail*, a small sail set over a gaff, which serves to spread the foot of the sail.

GAGE, a pledge or pawn, given by way of security.

Gage, a challenge to combat; that is, a gauntlet, glove, cap, or the like, cast on the ground by the challenger, and taken up by the accepter of the challenge.

Gage, in nautical language, the depth of water a vessel draws, *i.e.* the number of feet she sinks in the water. In a different sense, when a ship is to windward of another, she is said to have the *weather-gage* of such vessel.

Gage, among letter-founders, a piece of hard wood variously notched, used to adjust the dimensions, slopes, &c. of the different sorts of letters. In joinery it denotes an instrument to strike a line parallel to the straight side of a board. *Sliding-gage*, among mathematical-instrument makers, a tool for measuring and setting off distances.

The term *gage*, implying *measure*, as of depth, height, force, quantity, &c., is frequently used in composition to denote particular kinds of instruments; as sea-gage, tide-gage, wind-gage, rain-gage, &c., &c.

GAILLAC, the capital of a cognominal arrondissement, department of Tarn, France, on the right bank of the Tarn, 12 miles W. of Alby. It has an agricultural society, a communal college, hospital, theatre, and manufactures of wine casks, leather, brandy, &c. The vicinity is very fertile, producing some good wines, which constitute its principal trade. Pop. (1851) 8152.

GAIN, in *Architecture*, is the workmen's term for the bevelling shoulder of a joist on other timber.

GAINAGE, Gainagium (*q.d.* wainage), in our ancient writers, signifies the draught oxen, horses, wain, plough, and their furniture, which, when a villein was amerced, were left free, that agriculture might not be interrupted. The word also denoted the land itself, or the profit derived from its cultivation.

GAINSBOROUGH, a market-town and river port of Lincolnshire, on the right bank of the Trent, 21 miles above its junction with the estuary of the Humber, and 16 miles N.W. of Lincoln. It consists chiefly of one long well-paved street running parallel with the river, which is here crossed by a fine stone bridge of three arches. It has a neat church erected in 1748, several dissenting places of worship, a town hall, and a small theatre. The old hall called John O'Gaunt's palace is a curious oak-timber framed building, forming three sides of a quadrangle, and having a tower 78 feet high. Gainsborough possesses a free grammar and other schools, an athenæum, savings-bank, dispensary, &c. Ship-building is carried on; and there are manufactures of linseed cake, ropes, malt, and tobacco. Vessels of 200 tons burden can come up to the town. The gross amount of custom duties received at the port in 1852 was L.20,637. On 31st

December 1853, 11 sailing vessels of 620 tons, and 5 steam-vessels of 356 tons, were registered at the port; while during that year 214 vessels of 13,292 tons entered, and 237 vessels of 12,725 cleared at the port. Market-day, Tuesday. Pop. (1851), 7506.

GAINSBOROUGH, Thomas, a celebrated English landscape-painter, was born in 1737, at Sudbury in Suffolk. His father was a man of humble fortune, and unable to give him any but the scantiest education. The time which he ought to have spent in the school-room, he thus passed in the woods and fields, where, at an early age, he became imbued with a taste for the quiet beauties of nature, which he afterwards reproduced with so much effect in his early landscapes. He made a habit of sketching every picturesque object that struck his fancy, and before the age of twelve had acquired great facility in drawing, and some skill in colouring. At that early age he was sent to London to master his art, and supported himself by portrait-painting till his nineteenth year, when he married a lady of fortune. After his marriage he removed to Ipswich, thence to Bath; and in 1774 returned to London, where he enjoyed an extensive practice as a portrait-painter. At the foundation of the Royal Academy, Gainsborough was appointed a member of it, but does not seem to have taken any active interest in its proceedings. During the latter years of his life he suffered much from a cancer in the neck, which ultimately proved fatal, 2d August 1788.

It is as a painter of landscapes and fancy pieces that Gainsborough will be longest remembered by posterity. Sir Joshua Reynolds, indeed, in his *Character of Gainsborough*, says, "Whether he excelled most in portraits, landscapes, or fancy-pictures, it is difficult to determine." But the difficulty has been already solved. His portraits, it is true, were very highly valued by his contemporaries, and possessed the prime merit of being always admirable likenesses. But this was often their sole merit, for they were very frequently so roughly and carelessly finished, and scumbled in a manner so peculiar, that though they looked well at a distance, they had a blurred and indistinct appearance when viewed near at hand. However, the artist himself always regarded this as a peculiar merit in his portraits, which he always requested might be hung low in the exhibition, so as to be within reach of the closest scrutiny. But Gainsborough's real fame rests on his landscapes and fancy-pieces. His early style differed greatly from his later. In the former he copied nature in all her details with the fidelity of a photographer. In the latter he aimed at producing grand impressions by the effects of great breadth, and a judicious chiaroscuro. It is perhaps too much to claim for him, as some of his admirers have done, an equality with Rubens, Claude, or Ruysdael; but no one will now refuse to accept the verdict of Sir Joshua Reynolds, who says, that if ever this nation should produce genius sufficient to acquire to us the honourable distinction of an English school, the name of Gainsborough will be transmitted to posterity as one of the very first of that rising name.

GAIUS, or Caius, a celebrated Roman jurist in the time of Antoninus Pius and Marcus Aurelius. Great use was made of his voluminous works in the compilation of the *Digest*. His *Institutiones*, an elementary treatise on Roman law, was one of his most celebrated works. This work was long the ordinary text-book for those beginning the study of Roman law; but after the compilation of the *Institutiones* of Justinian, it fell into disuse, and was finally lost. In 1816, however, this long-lost and valuable work was discovered by Niebuhr in the library of the chapter at Verona. The MS. containing "Gaius" was a palimpsest, with the new writing, in general, directly over the old. The Institutes of Gaius are composed in a terse, clear style, and seldom fail of pure Latinity.

GALACTODENDRON, or Milk-Tree (in Spanish called *Palo de Vaca*), a South American tree of the natural order *Urticaceæ*, from the stem of which, when wounded, there flows a milky and nutritious juice, which forms an important article of diet among the poor natives of the districts where it grows.

GALACZ, or Galatz, a town and port of Moldavia, on the left bank of the Danube, between the mouths of the Sereth and Pruth, in Lat. 45. 25. N., Long. 28. 1. E. The town is ill-built and dirty, but has latterly been much improved. It has a large bazaar always well filled with merchandise, and numerous warehouses for grain and other produce. Since 1834, when it was made a free port, its trade has rapidly increased, and various English and other foreigners have formed establishments here. Vessels of 300 tons can come up to the town, and regular steam communication is maintained with Vienna and Constantinople. Being the only port of Moldavia, and indeed in the best position for becoming the port of the Danube, it promises at no very distant period to become a first-rate emporium. Moldavia and Wallachia are very productive provinces, being rich both in corn and cattle. Our imports of corn from these two provinces in 1853 were, wheat 227,143 qrs., maize 373,790 qrs., and other kinds 64,173 qrs. In 1851, the exports by sea from Galacz amounted in value to L.496,368, being chiefly wheat, maize, rye, tallow, hides, wine, and timber. The chief imports were British and Austrian manufactures, colonial products, &c. Pop. estimated at 25,000. (See M'Culloch's *Commercial Dictionary*, 1854.)

GALÆSUS, or Galesus, in *Ancient Geography*, a small river of Calabria, falling into the gulf of Tarentum, a few miles W. of that city. It flowed through rich pasture-lands browsed by the sheep which produced the famous Tarentine wool. The value of this product was very great, and that none of it might be lost, the sheep were sent to feed completely enveloped in skins. Hence the force of Horace's allusion to the

> Dulce pellitis ovibus Galæsi
> Flumen.

The stream is often mentioned by the Roman poets, and has thus acquired a wider fame than many Italian rivers ten times its size. Indeed so small was the Galæsus, that it has not been identified with certainty. Swinburne, who is probably the best authority on the subject, supposes that the Cervaro is the real Galesus; and his supposition tallies better with the descriptions of Livy and Polybius than any other that has been advanced. The local antiquaries have tried, though not very successfully, to identify the Galæsus with a small stream called Le Citrezze, which falls into the Mare Piccolo, or great port of Tarentum, on its northern side.

GALAPAGOS, a group of islands in the Pacific Ocean, so called from the Spanish *Galápago*, a land tortoise, from their abounding in that animal. They consist of six principal and seven smaller islands, lying between 1 N. and 2 S. Lat., and between 89 and 92 W. Long., about 700 miles from the continent of South America. The largest, Albemarle Island, is 60 miles in length, by about 15 in breadth. The highest part is 4000 feet above the sea. They are all of volcanic origin, and along their shores black dismal-looking heaps of broken lava everywhere meet the eye. In many places the lava cliffs are very high, while close to them the water is so deep that a ship cannot anchor even in a calm. In the interior are some valleys and plains of moderate extent and of great fertility. The land tortoises, called the great elephant tortoises, their feet being like those of a small elephant, are numerous, and grow to a great size, frequently weighing several hundred pounds. A small colony has been established on Charles Island, in a plain about 1000 feet above the sea. They cultivate bananas, sugar canes, sweet potatoes and Indian corn, and supply with these articles the whalers who resort to the island. The climate is healthy and the heat moderate, considering the geographical position of these islands.

GALAROZA, a royal town of Spain, in the province of Sevilla. It is situated near the left bank of the Murtiga, about sixty miles N.E. of Huelva, among calcareous hills, and enjoys the advantage of a very copious spring, whose waters are skilfully applied to irrigate its beautiful gardens. Meat is extensively cured here for the markets of Cadiz and Seville. The population is nearly 3000.

GALASHIELS, a thriving manufacturing town of Scotland, in the counties of Roxburgh and Selkirk, and in the parishes of Galashiels and Ladhope. It stands on both sides of the Gala, about a mile above its confluence with the Tweed, and is 33 miles distant from Edinburgh by the North British Railway. Galashiels was made a burgh of barony in 1599, when it contained 400 inhabitants; but it is mentioned in history nearly three centuries before that date. Until late in the eighteenth century, however, it was a mere village standing on the side of Gala Hill. Being situated in a rich pastoral district, yielding abundance of wool, a woollen-mill was erected here in 1791, in which was placed one set of engines. Since that date the trade of the town has steadily increased, so that now more than a mile of the picturesque valley of the Gala is covered with neat modern houses and mills. There are at present (1855) fifteen of the latter, of large size, which contain 46 sets of carding engines, employing 32,200 spindles. Yarns spun in England, sufficient to employ 12 sets of engines, are also brought here for manufacture into cloths. The wool formerly used was all of home growth; but now the wools of Germany and Australia almost exclusively occupy the looms. There are about 2300 persons employed in the trade, who receive L.4600 per month in wages, and turn out annually from L.250,000 to L.300,000 worth of goods, at manufacturers' prices. These goods are chiefly Tweeds, shawls, plaids, and tartans. The drainage of agricultural lands has been found seriously to affect the water-power of the Gala, the stream being greatly swollen after rains, and nearly dry in their absence. This has led to the general introduction of steam power, and to migration to the neighbouring town of Selkirk and to the village of Innerleithen. Besides this staple manufacture, Galashiels has a tannery, a skinnery, brewery, saw-mill, bone-mill, savings-bank, four bank agencies, and one weekly newspaper, the *Border Advertiser.* The places of worship are—two parish churches, two Free churches, two United Presbyterian churches, one Episcopalian and one Roman Catholic chapel, an Independent meeting-house, a Glassite and a Baptist place of worship. There are five public schools, a town library, a public reading-room, and a mechanics' institution with library. The town is a burgh of barony; but in 1850 it adopted the provisions of the police act, 13th and 14th Vict., cap. 33, and is now governed by a chief magistrate, two junior magistrates, and five commissioners. Pop. (1851) 5918. Abbotsford is about a mile and a half from the town, on the right bank of the Tweed.

In connection with Galashiels it may be mentioned, that it was from observations made here that the salubrious nature of the employment in wool manufactures was first particularly pointed out. In working up the wool there is a large consumption of oil, with which the air becomes impregnated, and which is thus imbibed into the system. Children working in the mills are in consequence healthier and heavier than those in the town not so employed; and weakly children are purposely sent to mill employment for the strengthening and development of their bodily frames. Mr M'Dougall, surgeon in Galashiels, was the first to call attention to this fact, and his observations have been confirmed by the further investigations of Professor Simpson.

GALATA, one of the suburbs of Constantinople. See Constantinople.

GALATIA, afterwards called also Gallo-Græcia, in *Ancient Geography*, an inland division of Asia Minor, bounded on the N. by Bithynia and Paphlagonia, E. by Pontus, S. by Cappadocia and Lycaonia, W. by Phrygia. These boundaries, however, varied at different periods in the history of Galatia. The river Halys flowed in a northerly direction through the centre of the province, the eastern half of which was watered by tributaries of that stream, while the Sangarius and its affluents rose among the mountains of the western half.

According to Strabo, Galatia was occupied by three Gallic tribes: the Trocmi who dwelt in the east, the Tectosages in the centre, and the Tolistobogii in the west. Each of these tribes was subdivided into four parts; and these were each ruled over by a tetrarch of their own. The power of the tetrarchs was limited by a senate of 300, before which also all capital cases were tried. Minor offences came under the cognizance of the tetrarchs and special judges appointed by them. This system continued in force till within about fifty years B.C. The three tribes all spoke the same tongue; and though in course of time they became Hellenized, their original language was still in use among them as late as the time of Jerome.

The only towns of importance in Galatia were Tavium, the capital of the Trocmi, a small town which speedily fell into decay; Ancyra, the capital of the Tectosages, and Pessinus, the chief town of the Tolistobogii, where a splendid temple was consecrated to Agdistis, the mother of the gods. The only other place of note in Galatia was Gordium, the ancient capital of Phrygia, and the scene of Alexander's famous exploit of cutting the Gordian knot.

Galatia took its name from a body of Gauls who invaded Asia Minor about the year 279 B.C. They had formed part of the army which invaded Greece under Brennus; but having quarrelled with that commander had left his standard, and marching into Thrace under generals of their own choice, advanced to Byzantium, whence they were invited by Nicomedes, king of Bithynia, to cross into Asia and help him in his struggle against his brother Zibætas. After performing the required services, they turned their arms against their employer, and ravaged the western half of Asia Minor. Their success allured over hordes of their countrymen, who readily took service with the Asiatic kings in their wars against each other. No oriental prince was found able to check them, until Attalus king of Pergamus defeated them in a great battle B.C. 239; and compelled them to settle in that part of the country, which after them was called Galatia. They still remained independent, however, and proved a formidable foe to the Romans in their wars with Antiochus. It was found necessary to direct a special army against them, and the result of the campaign was their complete subjugation to the power of Rome. Galatia, however, was not at this time reduced to a Roman province, but the Gauls were still allowed to choose their own kings. One of the most famous of these was Deiotarus, who, in return for the assistance which he gave the Romans, was rewarded with a grant of Pontus and Armenia Minor, and styled king by the senate. On the death of his son Amyntas, B.C. 25, Galatia became a Roman province. Theodosius the Great subdivided it for purposes of government into Galatia Prima, of which Ancyra was made the capital, and Galatia Secunda, with Pessinus for its chief-town.

GALATIANS, Epistle to the. The Pauline origin of this epistle is attested not only by the superscription which it bears (i. 1), but also by the unanimous testimony of the ancient church, (Lardner, *Works*, vol. ii. 8vo.) It is corroborated also by the style, tone, and contents of the epistle, which are perfectly in keeping with those of the Apostle's other writings.

The parties to whom this epistle was addressed are described in the epistle itself as "the churches of Galatia."

Into this district the gospel was first introduced by Paul himself (Acts xvi.) Churches were then also probably formed; for on revisiting this district some time after his first visit, it is mentioned that he "strengthened the disciples" (Acts xviii.) These churches seem to have been composed principally of converts directly from heathenism, but partly, also, of Jewish converts, both pure Jews and proselytes. Unhappily, the latter, not thoroughly emancipated from early opinions and prepossessions, had been seized with a zealous desire to incorporate the rites and ceremonies of Judaism with the spiritual truths and simple ordinances of Christianity. So active had this party been in disseminating their views on this head through the churches of Galatia, that the majority at least of the members had been seduced to adopt them (i. 6; iii. 1, &c.) To this result it is probable that the previous religious conceptions of the Galatians contributed; for, accustomed to the worship of Cybele, which they had learned from their neighbours the Phrygians, and to the theosophistic doctrines with which that worship was associated, they would be the more readily induced to believe that the fulness of Christianity could alone be developed through the symbolical adumbrations of an elaborate ceremonial (Neander, *Apostol. Zeitalter*, s. 400, 2te Aufl.) From some passages in this epistle it would appear also that insinuations had been disseminated among the Galatian churches to the effect that Paul was not a divinely-commissioned apostle, but only a messenger of the church at Jerusalem; that Peter and he were at variance upon the subject of the relation of the Jewish rites to Christianity; and that Paul himself was not at all times so strenuously opposed to those rites as he had chosen to be among the Galatians. Of this state of things intelligence having been conveyed to the apostle, he wrote this epistle for the purpose of vindicating his own pretensions and conduct, of counteracting the influence of these false views, and of recalling the Galatians to the simplicity of the gospel which they had received. The importance of the case was probably the reason why the apostle put himself to the great labour of writing this epistle with his own hand (vi. 11).

Respecting the time when and the place where this epistle was written, great diversity of opinion prevails. It seems, however, probable that it was written and despatched not long after Paul had left Galatia for the second time, and perhaps while he was residing at Ephesus (comp. Acts xviii. 23; xix. 1, sqq.)

Of commentaries on this epistle the most important are the following:—Borger, *Interpretatio Ep. Pauli ad Galatas*, 8vo, Lugd. Bat. 1807; Winer, *Pauli Ep. ad Gal. perpet. Annot. illustravit*, 8vo, ed. tertia, Lipsiæ, 1829; Rückert, *Commentar. üb. d. Brief Pauli an d. Gal.*, 8vo, Leipzig, 1833; Usteri, *Commentar. üb. d. Br. Pauli an d. Gal.* 8vo, Zürich, 1833; Hermann, *De Pauli Epist. ad Gal. tribus primis capitibus*, 4to, Lips. 1832.

GALAXY, or Milky Way (Gk. Γαλαξίας), the great luminous tract which encompasses the heavens like a coronal or girdle, and which is easily perceivable in a clear night, especially when the moon does not appear. It passes between Sagittarius and Gemini, and divides the sphere into two parts. It is unequally broad, and in some parts is single, in others double. See Astronomy, vol. iv. p. 86.

GALBA, the name of a patrician family at Rome. The most noteworthy members of this family were Sulpicius Galba, who flourished at the beginning of the second century B.C., and distinguished himself in the wars with Philip of Macedon; Sergius Galba, who was prætor B.C. 151, and held Lusitania as his province, in which office he made himself notorious by his atrocious cruelties, for which he was tried on his return to Rome, and narrowly escaped punishment; and Sergius Sulpicius Galba, emperor of Rome from June A.D. 68 to January A.D. 69. (For the details of his life and reign see Roman History.)

GALBANUM, a gum-resin procured from incisions made in the stems of *Galbanum officinale*, a perennial plant growing in Africa (near the Cape of Good Hope), in Syria and Persia. It is imported into this country from the Levant, in ductile masses composed of distinct yellowish tears agglutinated together by a darker substance, and is generally much mixed with impurities. It has a strong nauseous odour, and a bitter acrid taste. It is sometimes used in medicine as a stimulant antispasmodic, but is a drug of little importance.

GALDAR, a royal Spanish town in the N.W. of the Island Gran Canaréa, beautifully situated five miles from Las Palmas, in a plain, with good air and fine temperate climate. It contains 4052 inhabitants, a church, a monastery a short distance from the town, and six hermitages, numerous ruined houses and caves of the ancient inhabitants, with the ruins of an edifice or palace of the Guanche chiefs.

GALDO, Santa Maria de, a district of Spain, in Galicia, province and bishopric of Mondoñedo, and jurisdiction of Galdo. It contains 2130 inhabitants, and stands in the valley of Vivero, which extends from N. to S. to the banks of the river Landrove. Its agricultural productions and its industry are altogether similar to those of Vivero. See Vivero.

GALENA, a city in the state of Illinois, N. America, on the Fêve, six miles above its junction with the Mississippi. It is the metropolis of the great lead region of northern Illinois, and the commercial dépôt of an extensive and fine country, the river being at all seasons navigable to this point for the largest river steamers. The Galena branch of the Illinois Central Railway passes through the city, and the Galena and Chicago Union Railway gives it access to the lakes and roads leading eastward. The city was first settled in 1826. Pop. (1850), 6500.

GALENA, native sulphuret of lead. See Mineralogy.

GALENISTS, in *Medical History*, a name given to the followers of Galen, in contradistinction to the practitioners of the chemical school. The distinction of *galenical* and *chemical* in the method of treating diseases was occasioned by a division of the practitioners of medicine into two sects, on the introduction of chemistry into medicine. The term *galenical* was applied to those medicines that were easily formed, as by infusion or decoction, in contradistinction to *chemical*, or such as required more elaborate preparation, as by calcination, digestion, fermentation, and the like.

GALENISTS, a sect of religionists, who were so named from their first teacher Galenus Abrahams de Haan, a doctor of medicine, and a minister among the Mennonites at Amsterdam. The schism in which the Galenists originated took place in 1664 in the church of the Flemings at Amsterdam, in which were the two preachers Galenus Abrahams de Haan and Samuel Apostool. Galenus was a man whom even his enemies applauded for his eloquence and penetration. His teaching was in accordance with the views of the Arminians, that the Christian religion is not so much a body of truths to be assented to as of precepts to be obeyed; and he would have admission to the church and to the title and privileges of brethren open to all persons who merely believe the books of the Old and New Testament to be divinely inspired, and lived pure and holy lives. The Galenists are equally ready with the Arminians to admit all persons into their communion who call themselves Christians, and they are the only Anabaptists in Holland who refuse to be called Mennonites. The Apostoolians admit no one to membership who does not profess to believe the doctrines contained in the public formula of their religion. *Mosheim's Hist.*, Cent. xvii., sect. ii., pt. ii., chap. v., 7; *Wagnaer*, Amsterdam, pt. ii., pp. 195 and 237; Schyn's *Plenior Deductio Historiæ Mennonit.*, cap. xv., p. 318, and cap. xviii., p. 237; *Description of the City of Amsterdam*, in Dutch, vol. i., p. 500, &c.; Stoupa, *La Religion des Hollandois*, p. 20, &c.; and Bentheim's *Holländischer Schul und Kirschenstaat*, pt. i., chap. xix., p. 830.

GALENUS, Claudius, commonly called Galen, the most celebrated of the ancient medical writers, and a man who has exercised a greater influence on medical science than any other individual author of ancient or modern times. Of his personal history little is known except what is gathered from his own works; but these are so full of personal detail as to furnish sufficient material for a life. He was born at Pergamus in Mysia towards the close of the year 130 A.D. His father, whose name was Nicon, was an architect and geometrician of that city, and is highly praised by Galen for his many good qualities both of heart and head. His mother, on the other hand, is described as a second Xanthippe, differing only from her prototype by being worse than she. No expense was spared in educating the young Galen, whose teachers were the most celebrated scientific men of his native town. Stratonicus, a disciple of the Hippocratic school; Satyrus, an eminent anatomist; and Æschrion, an empiric. After the death of his father, whom he lost in his twentieth year, Galen went to study successively at Smyrna, Corinth, and Alexandria, which last was the most famous medical school of the ancient world. He likewise seized the opportunity of travelling in various other foreign countries. In A.D. 158 he was publicly invited by his fellow-citizens to return home, and was appointed physician to the gladiatorial school. Five years later he was compelled, by civil dissensions, to quit his native city, and he then betook himself to Rome, where his unparalleled success drew down upon him the jealousy and hatred of the Roman practitioners. For some time he bore up against the ill-treatment which he met with at their hands, and wrote and lectured for a number of years with ever-growing success, but in daily dread of being poisoned by his rivals. In A.D. 167, Galen at length left, partly to avoid an introduction to the emperor M. Aurelius, partly to revisit his native city. His departure was probably hastened by the breaking out of the pestilence at Rome. He had hardly settled down at Pergamus when he received orders to join M. Aurelius in the north of Italy. Soon after he joined the emperor the plague broke out with great violence in the Roman camp, and M. Aurelius instantly returned to Rome, taking Galen in his train. It was probably about this time that he prepared for the emperor the famous medicine called "theriaca," of which the royal patient took a little every day. During his stay at Rome Galen composed two of his best known works in the leisure moments of his extensive practice. These were his treatises *De Usu Partium Corporis Humani*, and *De Hippocratis et Platonis Decretis.* After this time his history is not very clearly ascertained. He seems to have left Rome and returned to Pergamus, visiting on his way the island of Lemnos, where he learned the method of preparing the "terra lemnia" or sigillata, a medicine then much in vogue. It is not fully known whether he ever returned to Rome; but it seems probable that he did. Neither the year nor the place of his death is thoroughly ascertained. Suidas, whose testimony is generally followed, says that he died when he was seventy years of age, which would place his death in the year 201. One of his Arabian biographers, however, makes him survive till his eightieth year; and another, Abul-faraj, states that he died in Sicily at the age of eighty-eight.

Galen is, on the whole, one of the most remarkable writers of antiquity. As is frequently the case, his worth was ill appreciated during his lifetime, but after his death his native city caused medals to be struck in his honour; and he became generally known by the title of "the wonderful." During his early residence at Rome, indeed, his skill had earned for him the titles of "Paradoxologus," the wonder-speaker, and "Paradoxopæus," the wonder-worker. But it was not on his skill as a physician alone or chiefly that his fame depended. He was one of the most extensively and variously learned men of his age, and is known to have written nearly five hundred distinct treatises on different subjects, including logic, ethics, and grammar. He seems to have entertained a very justifiable respect for himself and his influence and position, and to have looked down with perhaps too great contempt on his rivals and detractors. But the bitter disgust which he felt towards them is excusable, if we remember that he lived among them in daily terror of his life. It is remarkable that though Christianity was in Galen's time spreading apace, he seems to have known no more about it than might have been picked up in ordinary conversation. At least he only alludes to the Christians in one of his works as remarkable for their self-denial, temperance, chastity, and other virtues, never indicating, however, any personal sympathy for them in the persecutions to which they were exposed. For a detailed account of Galen's influence and position in medical science, see Anatomy, vol. ii., pp. 752–754.

The works now extant, attributed to Galen, amount to 123 separate treatises. Of these only eighty-three are undoubtedly genuine; nineteen are doubtful; forty-five confessedly spurious; nineteen are mere fragments; fifteen are comments upon portions of Hippocrates; while fifty are enumerated as still lying unpublished in various European libraries. There have been numerous editions of Galen's complete works, and also of some of the individual treatises. A list of those who have edited or illustrated Galen is given by Conrad Gesner in the Basle edition of 1561. The most important of these, as well as of others who have since followed in the same track, are named in the following list:—Jo. Bapt. Opizo, A. Lacuna, Ant. Musa Brassavolus, Aug. Gadaldinus, Conrad Gesner, Sylvius, Cornarius, Joannes Montanus, Joannes Caius, Thomas Linacre, Theodore Goulston, Caspar Hoffmann, Réné Chartier, Haller, and Kühn. There have been numerous Latin translations of Galen. Altogether, according to Choulant, there was one version in the fifteenth century; twenty-two versions in the following century; and none since. There have been also four editions of the Greek text; the first by the Aldi at Venice, in 5 vols. fol., 1525; the next, also in 5 vols. fol., Basle, 1538; the third, by Réné Chartier, bears date Paris, 1679, and amounts to 13 vols. fol.; the last and best is that by C. G. Kühn, Leipzig, 1821–1833.

GALERUS, or Galerum, diminutive Galericulum (probably allied to *galea*, helmet), in *Roman Antiquity*, was originally a head-dress worn by priests, but especially by the *flamen dialis.*[1] Its shape was probably a round cap formed of leather, with its top terminating in an apex. In later times the *galerus* was any kind of cap fitting close to the head like a helmet.[2] *Galerus*, as well as *galericulum*, also came to signify a peruke, wig, or covering for the head made of hair.[3] *Flamen dialis solus album habet galerum.*[4] See Albogalerus, vol. ii., p. 449.

GALIANI, Ferdinando, an eminent political economist, was born at Chieti, in the Abruzzo, Dec. 2, 1728. At eight years of age he was sent to Naples, where he received his elementary education. He devoted himself with ardour to the study of history, antiquities, the belles-lettres, and philosophy, and more particularly to political economy. At the age of sixteen he produced a *Memoir on the Coins of the period of the Trojan War;* and this early production first inspired him with the idea of his great work on money. He also translated Locke's treatise on *Money and Interest.* At the age of eighteen he undertook a work on the *Ancient History of the Navigation of the Mediterranean;* and in his great work, we find that he there made use of part of the materials which he had collected at this early age. A *jeu d'esprit*, which had nearly been attended with serious consequences, diverted him for some time from his graver studies. Having been charged by his brother Bernard to deliver, in his absence, a discourse in an academy of which he was a member, the president, looking only at the youth of Ferdinand, and being ignorant of his talents, would not permit him to proceed. The latter resolved to revenge himself in a manner that showed more spirit than prudence. It was the custom in this academy, as in several others, that when any great personage died at Naples, all the academicians published, in his praise, a collection of pieces in prose and verse. The executioner at Naples having died, Galiani seized the opportunity of turning the academy into ridicule. With the assistance of a friend, he composed in the course of a few days, a collection of serious pieces on this event, which were ascribed to each of the members, and in which their peculiar style and manner were so well imitated, that one of them confessed he should have been himself deceived, if he had not been perfectly certain that he had not written the piece to which his name was subscribed. This malicious and witty little volume appeared in 1749, under the title of *Componimenti varj per la Morte di Domenico Jannacone, Carnefice della gran corte della vicaria, raccolti e dati in luce da Gian. Anton. Sergio Avvocato Napoletano*. This Sergio was the president of the academy. The publication was eminently successful, and excited a sensation which the authors had not foreseen; and as they became afraid of being discovered by the publisher, they went directly to the minister Tanucci, confessed the fact, and got off for the performance of some spiritual exercises.

[4] Var. in Gell. x. 15.

Galiani soon effaced the impression made by this piece of youthful folly, by the publication of his *Treatise on Money*, which had employed the labour of several years. It appeared at Naples in 1750, when the author was only twenty-one. It was first published anonymously, and the author did not make himself known until the success of the work was decided. He afterwards travelled through the whole of Italy, was presented at the various courts, and admitted a member of some of the most celebrated academies. His next publication was a treatise entitled *Della perfetta Conservazione del Grano*, written, with his usual elegance, for the purpose of recommending an ingenious machine, invented by his friend Intieri, for drying and preserving grain.

Galiani was the first to form a collection of the volcanic productions of Vesuvius; and he wrote a learned treatise upon this subject, which, however, was not printed until about fifteen years afterwards. He presented the manuscript to Pope Benedict XIV. along with the collection itself, which was arranged in seven boxes, according to the order of the treatise. The collection was placed in the Museum of the Institute of Bologna, where it still remains. In presenting this collection to the pope, Galiani had written upon one of the boxes, *Beatissime Pater, fac ut lapides isti panes fiant*. His holiness, understanding the hint, gave him the prebend of Amalfi, worth 400 ducats a-year. In the lifetime of his uncle, whom he lost in 1753, he enjoyed a benefice of 500 ducats, which conferred upon him the episcopal dignity, and another living worth 600 ducats. His funeral oration, on the death of his patron, Benedict XIV., who died in 1758, procured him a high character for eloquence, and was one of his works which he himself most esteemed.

Galiani was one of the members of the academy of Herculaneum, established by King Charles III. for the purpose of illustrating the remains of ancient art discovered among the ruins of that city; and he furnished several memoirs, which were inserted in the first volume of that magnificent work, the *Antiquities of Herculaneum*. With the other academicians who were engaged in this labour, Galiani enjoyed the royal bounty, in a pension of 250 ducats.

In the month of January 1759 he was appointed secretary of state and of the royal household, and, soon afterwards, secretary to the French embassy; and he arrived at Paris in the month of June following. He applied himself with great zeal and assiduity to the acquisition of a correct French style of writing, his mastery of which he afterwards showed in his celebrated *Dialogues sur le Commerce des Blés*. The style of this work is so easy and elegant, that one would never suppose it to be the work of a foreigner. The manuscript was left in the hands of Diderot, and was published in 1770, with the date of London, and without the name of the author. The work excited great attention in France, and the best writers were loud and unanimous in praise of it. Voltaire wrote to Diderot, who had sent him a copy, in the following terms: "The powers of Plato and Molière seem to be combined in the composition of this work. I have as yet only read about two-thirds of it; and I expect the *dénouement* of the piece with great impatience." The same author again praises the work in his *Questions sur l'Encyclopédie*, in the article *Bléd ou Blé*.

Meanwhile, Galiani had returned to Naples, where, in addition to his office of member of the Council of Commerce, he received that of secretary to the same tribunal. These two situations brought him a revenue of 1600 ducats. In 1777 he was made one of the ministers of the *junto* of the royal domains, which had the charge of everything connected with the private patrimony of the king; an office which added 200 ducats to his income. His partiality for the writings of Horace inspired him with the idea of a treatise *Des instincts ou des gouts naturels et des habitudes de l'homme, ou Principes du droit de la nature et des gens, tirés des Poësies d'Horace;* a work which he left nearly complete, but which has never been published. There is a Life of Horace prefixed, much better and more complete than that which is inserted in the works of Algarotti. The project which he entertained of a dramatic academy induced him to attempt the composition of a comic opera, in a new and singular style. This was *The Imaginary Socrates*, of which he gave the plan to the poet Lorenzi, who put it into verse, and it was set to music by the celebrated Paesiello. The piece was performed with the greatest success throughout Italy, Germany, and even at St Petersburg.

A work of a different kind soon afterwards engaged his attention. In the war which broke out in 1778, between England on one side, and France and Spain on the other, Naples and some other powers had remained neutral; but their rights, as they conceived, were not sufficiently respected by the belligerent parties. Numerous writings appeared throughout Europe on the rights and duties of neutrals; and, among others, Galiani produced a treatise in Italian, *On the Duties of Neutrals towards Belligerent Powers, and of the latter towards the former*. It was published at Naples in 1782, in 4to. In the same year he was appointed first assessor to the general council of finance; a situation which he accepted the more readily, as its duties were analogous to his other studies; but he refused to touch the salary. A few months afterwards, however, the king presented him with the abbacy of Scurcoli, which was worth 1200 ducats per annum, after deducting all charges and pensions. The office of assessor of economy in the superintendence of the crown funds, to which he was appointed in 1748, added to his public duties, and likewise increased his income. Meanwhile his health, which was naturally weak, declined daily. On the 13th of May 1785 he had an attack of apoplexy; and in order to prevent a return, he travelled the following year through Puglia. In 1787 he made a longer journey, and went as far as Venice, where he was well received by all the men of letters, as he was also at Modena by Tiraboschi, and by Cesarotti at Padua. On his return to Naples his health rapidly declined; and he died Oct. 30, 1787, at the age of fifty-nine.

Besides the works already mentioned, Galiani left behind him a variety of interesting manuscripts. Among them are The Commentary on Horace, with the Life; The Lexicon of Words peculiar to the Neapolitan Dialect; A Poetical Translation of the Anti-Lucretius; A Miscellaneous Collection of Poetical Pieces; Several volumes full of facetious Letters, Novels, and Anecdotes; His Epistolary Correspondence, which would form of itself a pretty voluminous collection. A part of it was published at Paris in 1818, in two vols. 8vo. (See art. GALIANI, *Biogr. Univ.*, tom. xvi.) (J. C.)

GALICIA, the largest province of Spain, called by the Spaniards "El Reino de Galicia" (the kingdom of Galicia), and written with one *l*, although they write the name of the inhabitants with two (los Gallegos), forms the N.W. angle of the Peninsula, and is bounded by the Bay of Biscay, the Asturias, Leon, and Portugal. It contains the four modern provinces of Coruña, Lugo, Orense, and Pontevedra, with a total area of 16,000 square miles, and a population of 2,000,000.

Surface.

Mountains.

The surface of Galicia consists almost entirely of hills and mountains, which here and there embosom a small plain, and are intersected by numerous valleys, narrow, rugged, and scarcely accessible. The whole province indeed forms the western extremity of the direct course of the great Cantabrian mountain range. From the boundary of Asturias and Leon, the Sierra de Peñamarela enters Galicia, and sweeps in a northerly direction round by Mondoñedo, then turning southward, and passing by Lugo and Orense on the west, it terminates on the coast between Vigo and Tuy. The basin of the Miño and its tributaries is inclosed by this mountain range, under the names of the Sierra de Peñamarela, de Mondoñedo, de Lobo, and other local denominations, separating it from the valleys of all the other rivers entering the Atlantic or the Bay of Biscay. During the greater part of the year, many of the summits of this series of sierras are covered with snow. Another offshoot from the Cantabrian chain, after passing through the province of Leon, enters Galicia at the S.E. angle, when it extends from E. to W. to the coast, and forms the boundary between Portugal and Galicia. The basin of the Sil is shut in by this offshoot, and joined to that of the Miño, of which the Sil is the largest tributary, and hence the second river in Galicia.

Rivers.

This territory is drained and watered by innumerable mountain torrents and streams, of which no fewer than seventy are called rivers. The principal of these is the Miño (Minho), which derives its name from its ancient name *Minius*, and was so designated from the *minium* or vermilion found along its banks. It rises near Mondoñedo in the Sierra de Mondoñedo, and after a course of 170 miles in a S. and S.W. direction, it enters the Atlantic near the port of Guardia. In its course it receives numerous affluents, of which the principal is the Sil, and passes the towns of Lugo, Orense, Ribadavia, and Tuy. The Sil, which enters the Miño about ten miles above Orense, receives in its course the affluents Cabe, Bibey, and numerous smaller streams, all of which come from the mountains of Leon and Asturias. The river Tea rises on the W. flank of Monte Faro, and falls into the Miño above Tuy. The Tambre, the Ulla, and the Lerez flow in a S.W. direction, and fall into the sea by wide estuaries, which respectively bear the names of Ria de Muros y Noya, Ria de Arosa, and Ria de Pontevedra (*ria* being the Spanish of estuary).

Coast and harbours.

The coast of Galicia is everywhere bold, and may be safely approached by mariners; it is much more broken, however, than the coasts of Asturias and Biscay, being more exposed to the violent action of the strong currents of the Atlantic, which run in these latitudes at the rate of half a mile an hour. Hence many secure havens have been in the course of ages scooped out by the storms and currents, and its deep inlets thus formed with its lofty promontories give this peculiar feature to this coast. Rivadeo, on the left bank of the Miranda, has a safe and capacious harbour, with three fathoms water at ebb-tide. Vivero Bay is one mile wide, and runs three inland, affording good anchorage throughout, with from six to eight fathoms of water. Still further westward, the Bay of Stanques la Verre, or inlet of Barquero, on the E. side of the Punta de la Estaca, is an excellent harbour, three miles wide and six long, with anchorage in six fathoms. The harbour of Ferrol is said to be the best in Europe; it is ten miles in length, and from a quarter to half a mile in breadth, with sufficient depth of water to allow the largest vessels to approach the town, which stands five miles from the entrance, and frigates may pass two miles further up. The shores on both sides of this fine harbour are lofty and well-guarded by the castles of San Felipe and Palma, while the entrance, which is formed by piers, may be closed by a boom. Here are docks, arsenals, and magazines, though now in a very neglected state, which might afford ready means of equipping the largest fleet; and until a few years since there were here also marine schools and barracks for the accommodation of 6000 artificers. Ferrol is strongly fortified on the land side by a wall, on which 200 cannon might easily be mounted; and it contains a population of about 17,000, who subsist without any trade, except that which is afforded by the presence of the fleet, as foreign goods are prohibited from entering the port. A long narrow peninsula separates the bays of Betanzos and of Ayres from the harbour of Ferrol, opposite to which stands the port of Coruña. The great bay which forms the common entrance to all these inlets is the Portus Magnus of the ancients. About one mile N. of Coruña stands the famous lighthouse called the Tower of Hercules, or the Iron Tower, which was repaired in 1788. It is 92 feet high, with walls 4½ feet thick. The construction proves clearly that it was built by the Romans, and an inscription discovered near its foundation informs us that it was built by Caius Servius Lupus, architect to the town of Aqua Flavia, and that it was dedicated to Mars. The principal port on the western coast of Galicia is the deep, capacious Bay of Vigo, in which the largest vessels may ride securely one mile above the town.

Climate, soil, and productions.

Manufacture.

The climate of Galicia is variable—cold in the interior as compared with the other provinces of Spain, but temperate on the coast. The skies are cloudy, and rains very frequent. Forest trees abound on the hill slopes, and also chestnut trees, which supply much of the food of the peasantry. Large herds of cattle, mules, and asses browse on the abundant rich pasture of the valleys. The soil is generally stony, but when carefully cultivated, produces flax, maize, barley, wheat, abundance of fruit, and a considerable quantity of wine. Great numbers of pigs are reared; and the hams cured in this province are in great request. The woods abound with game in great variety, while the rivers and indented shores teem with fish, especially trout, salmon, anchovies, tunny, lampreys, and the bezugos or hog-fish—a singular species, which has no bones, and resembles the lamprey in the richness of its flavour. The fisheries on the coast are a profitable branch of industry, not only supplying food for the inhabitants, but being largely exported into Leon and the Castiles. The chief manufacture is linen, which is made in large quantities, and of good quality for domestic use.

People.

The Galicians (Gallegos) are a hardy, docile, and industrious people, resembling their neighbours, the Portuguese, much more in their habits than the other inhabitants of the

Peninsula. To most of the rest of the Spaniards, Galicians are very little known. They form their ideas of them from those who emigrate into the other parts of Spain. The district of La Coruña supplies the Castiles, as Pontevedra and Orense do Portugal. The emigrants remain absent during four or five years, after which they pay their homes a visit, and start forth again. Others only go down for the harvest time, and return like the Irish to enjoy their hardly-earned gains. Those who settle in Madrid become *reposteros* and managers in families. They are also well calculated, by their muscular frames, to do the porters' work of Spain and Portugal; hence the term *gallego* is synonymous with a boor, *ganapan*, or *mozo de cordel.* They are very numerous in Lisbon, Portugal being nearer their own homes than the Castiles.

Women.

When the men migrate, the women do all the drudgery at home, in the house and field, and painful it is to see them tugging at the plough. They are never idle; and the *rueca* or distaff is part and parcel of a Gallega as is the fan of an Andaluza. This hard work, with their bad fare, nips their beauty in the bud; few indeed are born good-looking, or even retain their good looks long. They are aged at thirty, and then seem models for witches, and even as if they never had been young. From the Gallegos a direct answer is scarcely ever obtained. In their wretched huts they seem not a whit improved since the time of Justin and Strabo. Still, now as then, they are proud of their pedigrees.

Language.

The language of Galicia is a harsh, uncouth dialect, quite unintelligible to Spaniards, who sneer at their use of *u* for *o*; and yet from it and the dialect of the Asturias the modern elegant and refined Castilian has sprung. These interesting keys to the origin of their language has never yet received the attention they deserve from the Spanish philologists.

Wild animals.

Among the woody hills there are numerous wolves and wild boars that descend into the plains, and sometimes commit great depredations among the flocks and herds.

Minerals.

Advancing northward, primitive formations begin to appear as the outline of the hills becomes bolder; and near Coruña lofty granitic ridges stretch as far as Cape Ortegal. These granites, which seem to be a continuation of those of Cornwall, contain an abundance of the common tin ore, the working of which is laborious, and not very profitable to the Galicians, who are far behind in scientific and mechanical appliances. There is strong probability that the Phœnicians visited Galicia as well as Cornwall and the Cassiterides for this tin ore. In former times, gold and silver were also among its mineral wealth; but at present lead, tin, and copper, which are found chiefly along the northern coast and along the banks of the Miño, are the only riches of which the mines of Galicia can boast.

Towns.

Galicia contains 6 cities, 70 towns, and rather more than 3000 villages. Coruña is now the capital of Galicia, and chief town of the province of Coruña. *Betanzos*, 11 miles W.S.W. from Coruña, is situated on a peninsula, formed by the junction of two streams, which flow unitedly into the Bay of Betanzos. It is an old town, and some of the narrow streets are still entered by ancient granite gateways. The population, about 5000, are mostly employed in the fisheries. *Ferrol* has already been mentioned among the harbours. *Lugo* stands 52 miles S.E. from Coruña, and is the capital of the modern province of Lugo. Under the name *Lucus Augusti*, Lugo was celebrated in Roman times for its warm sulphur baths. These *thermæ* have disappeared, but some remains of a dike against inundations testify their former magnificence. The present incommodious baths are on the left bank of the Miño, and they are beneficial in cutaneous and rheumatic disorders from the middle of June till the end of September. Close to these there is a mineral spring containing nitre and antimony. In September 1842 the *Calle de Batitales*, a Roman mosaic pavement was discovered, with designs of fish, animals, and other devices. The population of Lugo is (1855) nearly 8000. *Orense* (aquæ) *urentes*, "warm sea," was anciently celebrated for its warm baths, and those called *Las Burgas* are still frequented from July to September. They gush forth at the W. of the town from a granite rock almost boiling, and are turned to many useful purposes besides medical ones. Orense has very narrow streets, but is a clean, neat town, and the capital of the modern province of Orense. The population is about 7000. The town is pleasantly situated, encircled with hills, and rising gently from the Miño. The bridge over the river is a striking object, being 1320 feet long and 18 wide, defended by a castle on the town side. The grand arch is 156 feet span, and 135 in elevation from the bed of the stream, which is subject to sudden inundations. It was built in the year 1230 by Bishop Lorenzo, and repaired in 1449 by one of his successors, Pedro de Silva. It was in this city that the Suevi-Goths first renounced Paganism. *Pontevedra* is 80 miles S.S.W. of Coruña, and situated on the S. bank of the Lerez at its entrance into the Ria de Pontevedra. The town has its name from the long bridge which here crosses the Lerez; it signifies "old bridge." The town is well built, surrounded with walls, well paved, clean, and has a commodious harbour for small craft. It contains a population of about 5000. The *other principal towns*—Mondoñedo, Santiago de Compostola (formerly the capital of Galicia), Tuy, and Vigo—are given in their alphabetic order.

History.

The origin of the name of Galicia is very uncertain. Some suppose that it was given by the *Galli*, who, pursued by the Kymri, took refuge in Spain; while others adopt the notion that the name was given by its first inhabitants, the *Callicai* or *Gallæci.* In A.D. 408 the Suevians, Alans, and Vandals entered Spain, and became masters of several provinces, which they partitioned among them. Galicia fell to the Suevians, who chose for their chief Hermeneric (A.D. 411.) In 559 Theodomir and his son established and warmly defended Christianity in their dominions; but in 590 Luvigildus, king of the Visi-Goths, rendered himself master of Galicia, which he united to his own estates. In 713 the Moors invaded the kingdom, and were in turn driven out of it by Troïla, king of Leon and the Asturias. In 1065 Ferdinand I. erected Galicia into a separate kingdom for his second son, Don Garcia. But his tyranny and debaucheries excited the hatred of the nation so much that he was first driven from his throne in 1071, and two years afterwards deprived of all his estates by Alfonso, king of Castile. After that, the younger sons of the kings of Castile often held Galicia as an appanage, but only with the title of Count. These Counts remained independent till 1474, the date of the complete destruction of feodality by Ferdinand the Catholic. Since that time, Galicia has preserved no trace of its ancient grandeur and independence, except the name of kingdom, though only considered as a province of Spain. In 1822 the Cortés subdivided it into the present four small provinces, as already mentioned.

GALICIA, *Kingdom of,* a province of Austria, formerly constituting a part of Poland.

GALILEE (Γαλιλαία), the Greek form of the name given to one of the three principal divisions of Palestine, the other two being Judæa and Samaria. This name of the region was very ancient. It occurs in the Hebrew forms of *Galil* and *Galilah*, Josh. xx. 7; xxi. 3; 1 Kings ix. 11; 2 Kings xv. 29; and in Isa. viii. 23 we have גליל הגוים "Galilee of the nations" (Γαλιλαία ἀλλοφύλων, 1 Macc. v. 15; Matt. iv. 15.)

Galilee was the most northern of the three divisions, and was divided into Upper and Lower. The former district had Mount Lebanon and the countries of Tyre and Sidon on the north; the Mediterranean Sea on the west; Abilene, Ituræa, and the country of Decapolis on the east; and Lower Galilee on the south. This was the portion of Galilee which was distinctively called "Galilee of the nations," or of the "Gentiles," from its having a more mixed population, *i.e.* less purely Jewish than the others. Cæsarea Philippi was its principal city. Lower Galilee had Upper Galilee on the north, the Mediterranean on the west, the Sea of Galilee or Lake of Gennesareth on the east, and Samaria on the south. Its principal towns were Tiberias, Chorazin, Bethsaida, Nazareth, Cana, Capernaum, Nain, Cæsarea of Palestine, and Ptolemais. This is the district which was of all others the most honoured with the presence of our Saviour. Here he lived entirely until he was thirty years of age; and although after the commencement of his ministry he frequently visited the other provinces, it was here that he chiefly resided. Here also he made his first appearance to the apostles after his resurrection; for they were all natives of this region, and had returned hither after the sad events at Jerusalem (Matt. xxviii. 7).

Hence the disciples of Christ were called "Galileans." They were easily recognised as such; for the Galileans spoke a dialect of the vernacular Syriac different from that of Judæa, impure in comparison with that of the metropolis. The Galilean dialect (as we learn from Buxtorf, Lightfoot, and others) was of a broad and rustic tone, which affected the pronunciation not only of letters but of words. It partook much of the Samaritan and Syriac idiom; but, in the instance of Peter, it must have been the tone which bewrayed him, the words being seemingly too few for that effect.

GALILEO GALILEI, the founder of experimental science, was born at Pisa on the 15th of February 1564, being descended of a noble and ancient Florentine family, which, under the surname of Bonajuti, afterwards changed to that of Galilei, had filled distinguished offices in the state. His father, Vincenzo Galilei, was a man of considerable talent and learning, with a competent knowledge of the mathematics, and particularly devoted to the study of music, on the theory and practice of which he published several treatises. Vincenzo had three sons, Galileo, Michel Angelo, and Benedetto, and the same number of daughters, Giulia, Virginia, and Livia; but he was not opulent, and being burdened with a numerous family, was unable to provide for them expensive instructors. The subject of this notice exhibited early symptoms of an active and original mind, and even in his childhood showed a singular aptitude for mechanical contrivances, imitating with infinite address all sorts of machines, inventing new ones, or when, as often happened, he wanted the necessary materials for constructing these, adding new pieces to old ones. It is worthy of observation, that the boyhood of his great follower, Newton, whose genius in many respects closely resembled his own, was marked by a similar talent. Galileo commenced his literary studies at Florence, where his family resided; but, for the reason already stated, his masters were of the humblest kind. Knowing the disadvantages of his situation, however, Galileo resolved to supply by industry the want of better opportunities; and he applied with so much assiduity to the study of the classic models, that he soon laid the foundations of that extensive and solid literature to which he was afterwards indebted for the purity of his language and the elegance of his writings. His leisure hours were applied to the cultivation of music and drawing, in both of which arts he excelled. For the former he inherited his father's talent, which he displayed by performing skilfully on several instruments, especially the lute; and during the whole of his life this continued to be his favourite recreation amidst more serious pursuits. In the latter, which he had at one time thoughts of cultivating as a profession, he acquired so perfect a taste, that eminent contemporary artists did not scruple to own their obligations to him for his counsel and suggestions. Such was Galileo at the age of eighteen, when his father, becoming daily more sensible of the extent of his genius, determined, at whatever sacrifice, to give him the advantage of an university education. In 1581 he accordingly commenced his academical career in the university of Pisa, which he entered with the intention of studying medicine, from the profession of which his father hoped that he might one day procure an easy and honourable subsistence.[1] And, that he might not lose any kind of instruction which was to be obtained, he attended a course of peripatetic philosophy, such as it was then taught, in addition to that of medicine. But, called by the predestination of genius to unveil to mankind those wonders of nature, which their fanatical confidence in the opinions of Aristotle prevented them from seeing even when revealed, he could not bring himself to assent without conviction, nor to admit the authority of a master in questions which reason and experiment ought alone to decide. Actuated by this spirit, he several times ventured, in the academical discussions, to combat the firmest supporters of the Aristotelian dogmas, and in consequence he obtained the reputation of possessing an obstinate and contradictory disposition; for men do not easily reconcile themselves to the subversion of opinions, the stability of which they have long been accustomed to consider as incapable of being shaken; and hence the partisans of Aristotle found as great difficulty in doubting as Galileo did in admitting the authority of that master. It is not a little remarkable that, some years later, Descartes commenced in France, as Bacon did in England, the same war which Galileo had so boldly declared at Pisa; thus proving that the great regenerative efforts of the human mind are inevitably brought on by the force of circumstances and the natural progress of ideas, and that the men of genius who attach their names to these memorable revolutions, are themselves carried onward by their age, and precede it only by a few steps.

It was at this period, 1582, when he had scarcely completed his eighteenth year, that Galileo made the first and perhaps the finest of his discoveries. Happening one day to be in the metropolitan church of Pisa, he remarked the regular and periodic movement of a lamp suspended from the roof of the cathedral; he also observed the equal duration of its oscillations, whether great or small; and this he confirmed by repeated experiments. Having satisfied himself as to the phenomenon itself, he immediately perceived the use to which it might be applied for the exact measurement of time; and this idea having remained in his mind, he employed it fifty years afterwards (in 1633) for the construction of a clock intended for astronomical observations. In what manner this instrument was constructed, does not exactly appear; but it seems certain that it was employed for the purpose stated; and this, in our opinion, is sufficient to entitle Galileo to the honour of having been the first to make an application which afterwards became of so much importance to astronomy; for Huygens, who, in truth, rendered it incomparably more perfect, by employing the pendulum as the regulator of clocks, and not as the motive power alone, did not publish his researches on this subject until about the year 1658.

At the time of which we are here speaking, Galileo had no knowledge of the mathematics, nor even the least desire to learn them, not conceiving in what respect triangles and circles could conduce to the advancement of philosophy. The study of geometry was then at a very low ebb, not only in Italy, but in every country of Europe. Commandine, it is true, had recently revived a taste for the writings of Euclid and Archimedes; Vieta, Tartalea, and others had made considerable progress in algebra; and Guido Ubaldi and Benedetti had done something towards establishing the principles of statics, the only branch of mechanics as yet cultivated. But, with these exceptions, the application of mathematics to the phenomena of nature was scarcely thought of. Galileo's first inducement to acquire a knowledge of geometry arose from his partiality for music and drawing; he had heard his father repeatedly state, that these arts, of which he was passionately fond, had their principles in the relations of numbers and of position taught by the mathematics; and he now entreated to be instructed in a subject which promised to unfold to him the true theory of his favourite pursuits. But his father, apprehensive that a study which so strongly attaches those who take pleasure in it would diminish his zeal for medicine, told him to wait until he had completed his course. Galileo, however, was not satisfied; and as Ostilio Ricci, professor of mathematics in the university, frequently visited at his father's house, he besought this person to give him secretly some lessons in geometry. The professor consented, after having privately asked and obtained the consent of the father. But the young man had no sooner entered into that field of investigation for which nature had destined him, than his mind became engrossed by the pleasure he felt in the certain and entire possession of truth; from that moment medicine and philosophy were abandoned for Euclid; and all the efforts and remonstrances of his father, who desired to recall him to pursuits which he thought more useful, and even went so far as to prohibit him from holding any intercourse with Ricci, proved unavailing. The impulse had been given, and all attempts to counteract it were fortunately useless. Galileo had learned enough to study alone. He accordingly continued in secret the perusal of Euclid, at the same time keeping open beside him a Galen or an Hippocrates, in order to conceal the favourite book when his father entered. Having thus by stealth advanced as far as the sixth book, and being transported with the utility which he discovered in the science of geometry for giving force and method to the understanding, he resolved to avow his progress to his father, and entreat the latter no longer to oppose the decided bent of his mind. Vincenzo, perceiving that he was born for the mathematics, yielded to the irresistible predilection of his son, and permitted him to enter freely upon those speculations to which he thenceforward devoted all the energies of his highly-gifted intellect.

---

[1] In the matriculation lists of Pisa he is styled Galileo, the son of Vincenzo Galilei, a Florentine, scholar in arts. His entry is dated the 5th November 1581.

Having thus abandoned medicine, Galileo read with avidity the works of the ancient geometers, and then proceeded to study the treatise of Archimedes on floating bodies, which greatly delighted him. He now sought to multiply the applications of the method employed by the illustrious ancient in determining the proportions of an alloy of silver and of gold by successive weighings in water and in air; and for this purpose he invented an instrument similar in its uses to that which was afterwards called the hydrostatic balance. This invention, joined to his previous discovery respecting the movement of oscillation, and his new and free method of discussing subjects in philosophy, had already procured him considerable reputation, when he formed a connection with the Marquis Guido Ubaldi, then one of the most learned mathematicians of Italy. At the suggestion of this distinguished person, Galileo applied himself to consider the position of the centre of gravity in solid bodies; a choice of subject sufficiently indicating the estimate which Ubaldi had formed of his powers, considering that the question was one on which Commandine had recently written, and which at that time engaged the attention of geometricians of the highest order. Galileo, however, discontinued his researches on meeting with Valerio's treatise upon the same subject; but Ubaldi was so much struck with the genius displayed in the essay which Galileo presented to him, that he introduced the young geometer to his brother the Cardinal del Monte, who again warmly recommended him to John de' Medici and the Grand Duke Ferdinand of Tuscany, as a person of the highest promise. These illustrious personages gave him a most favourable reception, and soon afterwards bestowed on him the chair of mathematics in the university of Pisa, although he had as yet scarcely completed his twenty-fifth year.

Excited by this distinction, Galileo neglected nothing calculated to justify the preference which had been given him; and conceiving that a knowledge of the laws of motion is the basis of all solid study of nature, he undertook to establish them, not by hypothetical reasonings, as was the practice in the schools, but by real experiments. He thus demonstrated that all bodies, whatever be their nature, are equally affected by gravity; and that, if the spaces through which they descend in equal times are different, this depends on the unequal resistance opposed to them by the air, according to their different volumes. This important proposition Galileo completed long afterwards, in a work entitled *Dialoghi delle Scienze Nuove*, in which he established the true theory of uniformly accelerated motion. The novelty and beauty of his first experiments, performed before an immense concourse of spectators, excited great enthusiasm. But they at the same time embittered the animosity of the partisans of the ancient philosophy, who, seeing their whole science attacked, sought to destroy the innovator in the opinion of persons in power, and at length succeeded in raising against him such a host of annoyances and persecutions, that, in 1592, he was obliged to resign his chair at Pisa. He returned to Florence without employment, but durst not present himself in the house of his father, who had already made so many sacrifices on his account. He had the good fortune, however, to obtain from Guido Ubaldi a letter of recommendation to an opulent gentleman of Florence, of the family of the Salviati, who received him with extreme kindness, and afforded him the means of prosecuting his discoveries, until he could find some employment. With a view to serve him, Salviati also made him known to a Venetian nobleman of the name of Sagredo; an enlightened and influential man, who soon afterwards obtained for the youthful philosopher the chair of mathematics at Padua, which was conferred on him for six years. It was in gratitude for these seasonable benefits that Galileo gave the names of Sagredo and Salviati to the two interlocutors in his dialogues who support the true philosophy.

In his new situation, where he enjoyed greater freedom than he had done at Pisa, Galileo continued, with still more brilliant success, both his public lessons and his experimental researches. He constructed, for the service of the state, various machines of great utility; and he wrote for his pupils treatises on gnomonics, mechanics, spherical astronomy, and even fortification, according to the usage of the age, when many things were united which the progress of knowledge has since separated. In 1597, he invented the thermometer[1] and the proportional compass or sector, which he called the military compass, because he had principally intended it for the use of engineers. In 1599, his commission having expired, the senate renewed it for another six years, with an increase of salary, which Galileo repaid to the republic by new discoveries. In 1604, an unknown star of extraordinary brightness having suddenly appeared in the constellation of Serpentarius, Galileo demonstrated, by his observations, that this body was placed far beyond what the peripatetics called the elementary region; nay, that it was much more remote than all the planets, contrary to the formal and infallible opinion of Aristotle, who maintains that the heavens are incorruptible and free from all mutation. He also made researches on natural magnets, and succeeded in considerably augmenting their power by means of capping or casing them. His commission as professor was renewed a second time in 1606, with additional advantages, for which he testified his gratitude, as before, by increased diligence in the prosecution of his discoveries. But envy, which had never lost sight of him, exerted herself to disturb that peace which is so necessary to the successful pursuit of science. In 1604, on the occasion of his researches respecting the new star, he had been grossly abused by one Baltasar Capra of Milan. This man had the audacity to publish a Latin treatise on the proportional compass, in which he represented himself as the real inventor of that instrument; but the calumny was so gross that nobody was deceived by it; Galileo confounded his adversary, and the work of Capra was prohibited as a defamatory libel. Nor was this the only instance in which he had to vindicate his right of property in his own inventions. He frequently found himself ill recompensed for the readiness with which he communicated the results of his investigations; but he always raised himself by new discoveries, far above these disgraceful attempts to appropriate the fruits of his genius.

---

[1] The original idea of this instrument belongs to the Greek mathematician Hero; and even Santorio, who has been named by Italian writers as the inventor, and, at one time, claimed the invention as his own, refers it to him. In 1613, Sagredo, who has been

The year 1609 was signalised by a discovery on the part of Galileo, which forms one of the most solid foundations of his glory. In the month of April or of May, a rumour was circulated in Venice that a Dutchman had presented to Count Maurice of Nassau an instrument, by which means distant objects appeared as if they were near at hand. On this slight and cursory hint Galileo immediately applied himself to discover whether the thing was possible, conformably with the passage of the luminous rays through spherical glasses of various forms. Some attempts made with lenses which he had at hand produced the desired effect; and next day he gave an account of his success to his friends, which, in fact, was nothing less than the invention of the telescope. A short time afterwards he presented several of these instruments to the senate of Venice, accompanied with a description in which he unfolded the immense consequences for nautical and astronomical observations which would certainly result from the discovery; and in recompense of his ingenuity his commission as professor was continued for life, with an allowance of salary triple that which he had previously received. Galileo neglected nothing calculated to evince his gratitude, or to add to the claims which had merited these favours. Indefatigable in his researches, he invented the microscope; he also improved his telescope, and soon brought it to a state fit to be applied to the observation of the heavens. He then perceived what as yet no mortal eye had ever seen; the surface of the moon, like that of the earth, bristled with high mountains and ploughed with deep valleys; Venus, presenting, like the moon, phases which prove her rotundity; Jupiter environed with four satellites, who accompany him in his course; the milky way; the nebulæ; in a word, the whole heavens bespangled with a countless multitude of stars too small to be even perceived by the naked eye. It is more easy to conceive than describe the surprise and delight which the first view of so many wonders must have inspired him withal, as well as the admiration which they could not fail to produce when they were known. A few days having sufficed to pass them in review, he hastened to announce his observations to the world in a publication entitled *Nuncius Sidereus*, or Celestial Courier, which he dedicated to the princes of Medici, and which he continued at intervals, in proportion as he discovered new objects. He also observed that Saturn sometimes appeared under the form of a simple disc, and sometimes with two appendages which seemed two small planets; but it was reserved for another astronomer (see HUYGENS) to demonstrate that these appearances were produced by the ring with which Saturn is surrounded. Galileo also discovered moveable spots on the globe or disc of the sun, whom the peripatetics had declared incorruptible, and did not hesitate from these to infer the rotation of that planet. He remarked that feeble light which, in the first and last quarter of the moon, renders visible, by means of the telescope, the part of her disc which is not then directly enlightened by the sun; and he concluded rightly that this effect was owing to the light reflected towards the moon by the earth. The continued observation of the spots of the moon satisfied him that that planet always presents nearly the same aspect; but in these he nevertheless recognised a species of periodic oscillation, to which he gave the name of libration, the exact laws of which were afterwards made known by Dominic Cassini. In a word, not less profound in following new truths to their consequences than subtile in discovering them, Galileo perceived the use to which the motions and eclipses of the satellites of Jupiter might be turned for the measure of longitudes; and he even undertook to make a sufficient number of observations of these stars to enable him to construct tables for the use of navigators.

After so many and so admirable discoveries, we have good reason to be astonished that any one should dream of denying to Galileo the invention of the telescope, with which he had made them; as if, in such a case, the inventor was not he who, guided by certain rules and by great views, knew how to perform wonders with that which chance had thrown rude and unfashioned into incapable hands. If he who, in Holland, accidentally joined two glasses of unequal curvature, was really the inventor of the telescope, why then did he not turn it towards the heavens, the most beautiful and sublime application of that instru-

---

already mentioned as the friend of Galileo, writes to him in the following terms:—"I have brought the instrument which you invented, into several convenient forms, so that the difference of temperature between two rooms is seen as far as a hundred degrees." The date of this communication, which incidentally establishes the invention of Galileo, is anterior to the claims of Santorio, and also to those of Drebbel, a Dutch physician, who obtained, and still preserves in Germany, the honour of having invented this instrument. Another testimony may be added. In 1638, Castelli wrote to Cesarini that he remembered an experiment shown to him more than thirty years before by Galileo, who took a small glass bottle, about the size of a hen's egg, the neck of which was twenty-two inches long, and as narrow as a straw. "Having well heated the bulb in his hands, and then introduced its mouth into a vessel containing water, he withdrew his hand from the bulb, on which the water rose in the neck of the bottle more than eleven inches above the level of that in the vessel; and this principle he employed in the construction of an instrument for measuring heat and cold." Galileo's thermometer, therefore, consisted merely of a glass tube ending in a bulb, the air in which, being partly expelled by heat, was replaced by water from a glass in which the open end of the tube was immersed; and the different degrees of heat were indicated by the expansion of the air which still remained in the bulb, so that the scale would be the reverse of that now in use, as the water would stand at the highest level in the coldest weather. In other words, it was a compound of the barometer and thermometer.

ment? Why did he leave to Galileo the happiness and glory of overturning, in the eyes of all, ancient prejudices, of consolidating by the clearest proofs the system of Copernicus, and of aggrandising the celestial spaces beyond all that the imagination could have conceived? But however this may be, it is easy to comprehend to what a height so many and so great discoveries must have raised the views of Galileo; he perceived all the consequences which resulted from them relatively to the constitution of the universe; and, indeed, how could they escape him who, having taken nature as his guide, had, during his whole life, preserved his mind open to her impressions?[1] He concealed none of these high consequences, which formed as it were the soul of his writings and conversation; and he considered himself as henceforth entitled to despise errors too gross to be honestly maintained.

But, unfortunately for himself, he was no longer under the protection of Venice. Yielding to the instances of the Grand Duke of Tuscany, who had named him mathematician extraordinary, and loaded him with favours, he had quitted Padua, where he enjoyed the utmost freedom, for Florence, where such a thing as liberty was scarcely known. Honoured by the senate of Venice, and united by the ties of friendship with several of the most distinguished senators, he could publish his opinions without danger to himself as long as he remained within the territories of that state. But, in the end, experience proved that he could have no such security at the court of a prince, obliged at least to keep up appearances with the court of Rome. Besides the number of envious persons whom his great merit had exasperated against him, his discoveries made to him enemies of all those who had hitherto taught the ancient doctrines; and of these persons by far the greater part were ecclesiastics. Accordingly, some spread it abroad that his discoveries in the stars were pure visions, comparable only to the voyage of Astolphus; others affirmed that they had had the telescope in their possession during entire nights, and that they had seen nothing of all that which Galileo had announced; and a preacher was found who, malicious enough to convey a dangerous allusion in a pun, took as his text the words of the Gospel, *Viri Galilæi, quid statis adspicientes in cœlum?* It was thus that the countrymen of Copernicus had publicly ridiculed him on the stage; and it was thus that, at a later period, the reformed of Holland persecuted Descartes, who had taken refuge amongst them.

But the most certain method of reaching Galileo was to begin by prohibiting the doctrine of Copernicus, which he supported and propagated with so much distinction. This was accordingly effected by representing it as contrary to Scripture, and denouncing it to the holy see. Galileo endeavoured in vain to allay the storm, by publishing, in 1616, a letter addressed to the Grand Duchess of Tuscany, in which he undertook to prove theologically, and by reasons deduced from the Fathers, that the terms of Scripture might be reconciled with his new discoveries respecting the constitution of the universe. But this production only afforded a new handle to his adversaries, who maintained that he had rested his defence on an opinion which was itself erroneous in point of doctrine. He was cited to appear personally at Rome, and constrained to repair thither to defend himself. But neither the arguments which he urged in support of his opinions, nor the justice which they were forced to render to his knowledge, his merit, and even his catholicity, could prevent an assembly of theology, named by the pope, from coming to the following conclusion: "To maintain that the sun is placed immoveable in the centre of the world, is an opinion absurd in itself, false in philosophy, and formally heretical, because it is expressly contrary to the Scriptures; to maintain that the earth is not placed in the centre of the world, that it is not immoveable, and that it has even a daily motion of rotation, is also an absurd proposition, false in philosophy, and at least erroneous in point of faith." Confounded at this deliverance, Galileo employed all the arguments which the truth suggested to him in defence of a doctrine which his observations had rendered indubitable; but his efforts were unavailing; his reasonings were disregarded; and as he had not showed sufficient deference to the decision of the holy office, he was personally interdicted from professing in future the opinion which had just been condemned.[2]

---

[1] "The interpreter of the works of nature is experiment," says Leonardo da Vinci; "that is never wrong: it is our judgment which is sometimes deceived, because we expect results which experiment refuses to give. We must consult experiment, and vary the circumstances, till we have deduced general rules, for it alone can furnish us with them. But, it will be asked, what is the use of these general rules? I answer, that they may direct us in our inquiries into nature and the operations of art. They keep us from deceiving ourselves and others, by promising ourselves results which we can never obtain." (Venturi, *Essai sur les Ouvrages de Leonardo da Vinci.*)

[2] It has been contended that the treatment which Galileo experienced on this and a subsequent occasion was caused, not by his maintaining the true system of the world, which, in the above declaration, is formally condemned as "false in philosophy and erroneous in faith," but solely by his persisting in the endeavour to prove that the Scriptures were reconcilable with the Copernican theory. "Ce philosophe (Galileo)," says Bergier, "ne fut point persécute comme bon astronome, mais comme mauvais théologien. C'est son entêtement à vouloir concilier la Bible avec Copernic, qui lui donna les juges. Mais vingt auteurs, surtout parmi les Protestans, ont écrit que Galilée fut persécuté et imprisonné pour avoir soutenu que la terre tourne autour du soleil, que ce système a été condamné par l'Inquisition comme faut, erroné, et contraire à la Bible." (*Encyclopédie Méthodique*, art. *Sciences humaines*, Paris, 1790.) This is a complete misrepresentation of facts known to every one. So far was Galileo from persisting in an attempt to reconcile the Bible with Copernicus, that he regarded this as a matter altogether indifferent, and indeed beside the real question. "I am inclined to believe," says he in his letter to the Grand Duchess of Tuscany, "that the intention of the sacred Scriptures is to give mankind the information necessary for their salvation, and which, surpassing all human knowledge, can by no other means be accredited than by the mouth of the Holy Spirit. But I do not hold it necessary to believe that the same God who has endowed us with senses, with speech, and with intellect, intended that we should neglect the use of these, and seek by other means for knowledge which they are sufficient to procure us; especially in a science like astronomy, of which so little notice is taken in the Scriptures, that none of the planets, except the sun and moon, and once or twice only Venus, under the name of Lucifer, are so much as named there. This therefore being granted, I think that in the discussion of natural problems we ought not to begin at the authority of texts of Scripture, but at sensible experiments and necessary demonstrations; for from the divine word sacred Scripture and nature did both alike proceed; and I conceive that, concerning natural effects, that which either sensible experience sets before our eyes, or necessary demonstrations prove unto us, ought not upon any account to be called in question, much less condemned, upon the testimony of Scripture texts, which may under their words couch senses seemingly contrary thereto." Can any thing be more explicit than the contradiction of the assertion of Bergier contained in these words? Is there any evidence here of Galileo's alleged "entêtement à vouloir concilier la Bible avec Copernic?" But the philosopher proceeds in continuation: "Again, to command the professors of astronomy that they of themselves should see to the confuting of their own observations and demonstrations, is to enjoin a thing beyond all possibility of being done; for it is not only to command them not to see that which they do see, and not to understand that which they do understand, but it is to order them to seek for and find the contrary of that which they happen to meet with. I would entreat these wise and prudent fathers that they would with all diligence consider the difference which exists between opinionative and demonstrative doctrines; to the end that, well weighing in their own minds with what force necessary inferences urge

Galileo returned to Florence in 1617, and resumed, with what grief may be easily imagined, the course of his astronomical labours. But his love for these sublime truths, of which he considered himself as the depositary, increasing in proportion to the efforts made to extinguish it, he undertook to silence, if he could not persuade, his adversaries, by collecting into a body all the physical proofs of the motion of the earth and the constitution of the heavens; and during sixteen entire years he was engaged in this work. All that the finest genius could imagine in point of ingenuity, or the purest tāste admit in point of elegance, he employed to render the truth attractive. But it is not a learned treatise which he presents to us as the fruit of his labour and talents; it is merely a continued simple dialogue between two of the most distinguished personages of Florence and Venice, and a third interlocutor, who, under the name of Simplicius, undertakes to re-produce the "invincible arguments" of the peripatetics; and each perfectly sustains the part assigned to him. The two men of the world possess instruction, without system, and without prejudices; they discuss, examine, propose doubts, and only yield to cogent reasons. The good Simplicius, on the other hand, is altogether scholastic; he neither understands nor desires to comprehend any thing but Aristotle; he judges things true or false according as they are conformable or opposed to the assertions of his master; the least pleasantry on this subject is insupportable to him, and he yields not to any kind of conviction. The style of each of the interlocutors is also perfectly adapted to his character, without ceasing however to preserve, amidst these shades of distinction, an exquisite elegance, united with the most felicitous choice of expressions.

But if great genius was required for the composition of such a work, equal address was necessary to obtain permission to publish it; and this Galileo undertook to procure even in Rome itself. In 1630 he proceeded to that city, and having waited on the master of the sacred palace, boldly presented his work as a collection of new scientific fancies, at the same time requesting him to have the goodness to examine it scrupulously, to retrench whatever might appear to him exceptionable, and indeed to criticise it with the greatest severity. The prelate, not suspecting any thing, read it once and again; handed it to one of his colleagues for his opinion; and, not seeing any thing reprehensible in the work, set his hand to the most ample approbation of its contents. But the permission thus obtained was not sufficient; for, in order to profit by it, the work must be printed at Rome; and the numerous enemies of Galileo in that city would not have failed to explode the mine which the philosopher was himself charging to blow them up. On the pretext of some difficulty of communication between Rome and Florence, occasioned by a contagious distemper which then prevailed, Galileo accordingly wrote to the master of the sacred palace, soliciting permission to print his work at Florence, on the condition of having it again examined in that city. But the prelate, who perhaps began to suspect some deception, made difficulties; pointed out to Galileo a new censor; and demanded to see the approbation which he had previously given, in order, as he said, to revise the terms in which it had been conceived. With this request Galileo could not refuse to comply; but the prelate having once got hold of the document, refused to restore it, or to give any answer in explanation of his conduct; so that Galileo, after making every effort to recover it, and even causing it to be demanded by the ambassador of Tuscany, was compelled to abandon the pursuit as hopeless; and, contenting himself with the approbation of the censor of Florence, which he now managed to obtain, he published his work in 1632.

To shield himself as much as possible from prosecution, he however imagined the singular expedient of presenting his dialogues to the public as an apology for the judgment of Rome, by which the doctrine of Copernicus had been condemned. "Some years ago," says he, in the commencement of the introduction, which is addressed to discreet readers, "a salutary edict was promulgated at Rome, which, in order to obviate the perilous scandals of the age, enjoined an opportune silence as to the Pythagorean opinion of the earth's motion. There were not wanting persons who rashly asserted that this decree had originated, not in a judicious examination, but in ignorance and passion; and complaints were even heard that councillors unexperienced in astronomical observations should have attempted by hasty prohibitions to clip the wings of speculative minds. When I heard these rash lamentations, my zeal would not suffer me to remain silent; and being fully informed in regard to that most prudent determination, I thought it proper to appear publicly on the theatre of the world as a witness of the actual truth. I happened at that time to be in Rome; I was admitted to the audiences, and enjoyed the approbation, of the most eminent prelates of that court; nor did the publication of the decree pass without my receiving some previous intimation of the circumstance.[1] Wherefore it is my intention, in this present work, to show to foreign nations that as much is known of this matter in Italy, and particularly in Rome, as ultramontane diligence ever formed any notion of; and, collecting together all my own speculations on the Copernican system, to give them to understand that the knowledge of these preceded the Roman censures, and that from this country proceed not only dogmas for the salvation of the soul, but also ingenious discoveries for the gratification of the understanding. With this object in view, I have taken up in the dialogue the Copernican side of the question, treating it as purely a mathematical hypothesis, and endeavouring in every artificial manner to represent it as having the advantage, not over the opinion of the stability of the earth absolutely, but according to the manner in which that opinion is defended by some who indeed profess to be peripatetics, but retain only the name, and are contented without improvement to worship shadows, not philosophizing with their own reason, but only from the recollection of four

---

us, they might the better assure themselves that it is not in the power of professors of demonstrative sciences to change their opinions at pleasure, and adopt first one side and then another; and that there is a great difference between commanding a mathematician or a philosopher, and the disposing of a lawyer or a merchant; and that the demonstrated conclusions touching the things of nature and of the heavens cannot be changed with the same facility as the opinions are what is lawful or not in a contract, bargain, or bill of exchange. Therefore, first let these men apply themselves to examine the arguments of Copernicus and others, and leave the condemning of them as erroneous and heretical to whom it belongs; yet let them not hope to find such rash and precipitate determinations in the judicious and holy fathers, or in the absolute wisdom of him who cannot err, as those into which they suffer themselves to be hurried by some particular affection or interest of their own. In these and such other positions, which are not directly articles of faith, no man doubts but his holiness has always an absolute power of admitting or condemning them; but *it is not in the power of any creature to make them to be true or false, otherwise than of their own nature and in fact they are.*"

[1] Delambre, whose prejudice against Galileo is as unreasonable as his partiality to Kepler is marked, quotes this sentence as an instance of mis-statement of facts on the part of Galileo. With all his acknowledged ability, the historian of astronomy does not seem to have perceived, what must be obvious to almost every reader, that the whole passage is ironical, and that in the very sentence which he has cited there lurks a bitter sarcasm. (*Histoire de l'Astronomie Moderne*, tome i. p. 666.)

principles imperfectly understood." Any one who peruses a few pages of the dialogues will be at no loss how to interpret this declaration, nor will he feel any surprise that those whom Galileo here pretended to vindicate should have evinced but little gratitude for such a justification. But what can scarcely be imagined now, is the fury which the appearance of this work excited amongst the theologians of Rome, almost all of whom were ardent peripatetics. In vain did Galileo attempt to escape by alleging that his book had been submitted to the judgment of the holy see; in vain did he, as a last resource, protest that his only object had been to expound, in a philosophical manner, the two systems of Ptolemy and Copernicus. His enemies would not suffer any such excuse to be listened to. Still there remained to him some hope, founded upon the personal esteem of Pope Urban VIII., who, on a former occasion, had given him a most gracious reception, and had even paid his astronomical discoveries the compliment of celebrating them in bad verse; but the holy father having been persuaded that Galileo had intended to represent him under the character of Simplicius, his wounded self-love rendered his severity inexorable.[1] Notwithstanding the intercession of the Grand Duke of Tuscany, and the earnest solicitations which this prince caused to be made by his ambassador, the work of Galileo was delated to the Inquisition, and the author himself ordained to appear before that formidable tribunal.

The power of Rome was then supreme; it was necessary to obey. Neither the infirmity of his health, nor the pain he suffered from a rheumatic complaint which afflicted him, could procure an exemption from that sorrowful journey. This was in 1633, Galileo being then in the sixty-ninth year of his age. "I arrived at Rome," says he, in one of his letters, "on the 10th February, and was remitted to the clemency of the Inquisition, and of the sovereign pontiff, Urban VIII. who had some esteem for me, although I could not compose epigrams or write little amatory sonnets. I was put under arrest in the delicious palace of the Trinità de' Monti, the residence of the ambassador of Tuscany. Next day I received a visit from Father Lancio, commissary of the holy office, who took me with him in his coach. By the way he put to me a number of questions, and showed a great desire that I would repair the scandal which I had given to all Italy by maintaining the opinion of the motion of the earth; and to all the mathematical reasons which I could oppose to him, he could make no other answer than this: *Terra autem in æternum stabit, quia terra in æternum stat.* In discoursing thus we arrived at the palace of the holy office. I was presented by the commissary to the assessor, with whom I found two religious Dominicans, who civilly informed me that I would be permitted to explain my reasons before the congregation, and that afterwards I should be heard as to my grounds of excuse, if I was found guilty. The Thursday following I appeared before the congregation, and applied myself to the exposition of my proofs. But, unfortunately for me, they were not apprehended; and, notwithstanding all the pains I took, I could not succeed in making myself understood. My reasonings were cut short by bursts of zeal; they spoke to me only of the scandal which I had occasioned; and always opposed to me the passage of Scripture on the miracle of Joshua as the victorious piece of my process. This brought to my recollection another passage where the language of the sacred book is evidently conformable to popular ideas, since it is said that *the heavens are solid, and polished like a mirror of brass.* This example appeared to me one in point to prove that the expression of Joshua might be similarly interpreted; and the consequence seemed to me perfectly just. But no regard whatever was paid to it; and all the answer I received consisted of shrugs of the shoulders."[2] On the 30th of April Galileo was sent back to the residence of the ambassador, with a prohibition not to go beyond the *enceinte* of the palace, but with permission to walk freely in the extensive gardens attached to it. On the 22d of June he was again brought before the tribunal to hear the sentence read, and pronounce the abjuration dictated to him, according to which the venerable philosopher was made to say, "I abjure, curse, and detest the error and heresy of the motion of the earth," &c. and to promise that he would never more in future say or assert any thing, verbally or in writing, importing "that the sun is the centre of the world, and immoveable; and that the earth is not the centre of the world, and moveable." This expiation being completed, his dialogues were prohibited; he was condemned to suffer imprisonment for an indefinite period; and, as a salutary punishment, he was ordained to recite once a week for three years, the seven penitential psalms. Such was the unworthy recompense of one of the greatest geniuses that has ever enlightened humanity.[3]

[2] Letter of Galileo, cited by Tiraboschi.

[3] The sentence of the Inquisition on Galileo, one of the most remarkable records of intolerant ignorance and bigoted folly to be found in the history of science, is conceived in the following terms:—"We, the undersigned, by the grace of God, cardinals of the Holy Roman Church, Inquisitors General throughout the whole Christian Republic, Special Deputies of the Holy Apostolical Chair against heretical depravity: Whereas you, Galileo, son of the late Vincenzo Galilei of Florence, aged seventy years, were denounced in 1615 to this holy office, for holding as true a false doctrine taught by many, namely, that the sun is immoveable in the centre of the world, and that the earth moves, and also with a diurnal motion; also, for having pupils whom you instructed in the same opinions; also, for maintaining a correspondence on the same with some German mathematicians; also, for publishing certain letters on the solar spots, in which you developed the same doctrine as true; also, for answering the objections which were continually produced from the holy Scriptures, by glozing the said Scriptures according to your own meaning; and whereas thereupon was produced the copy of a writing, in form of a letter, professedly written by you to a person formerly your pupil, in which, following the hypothesis of Copernicus, you include several propositions contrary to the true sense and authority of the holy Scripture: therefore this holy tribunal, being desirous of providing against the disorder and mischief which was thence proceeding and increasing, to the detriment of the holy faith, by the desire of his holiness, and of the most eminent lords cardinals of this supreme and universal Inquisition, the two propositions of the stability of the sun, and motion of the earth, were *qualified* by the *theological qualifiers* as follows: 1st, *The proposition that the sun is in the centre of the world, and immoveable from its place, is absurd, philosophically false, and formally heretical, because it is expressly contrary to the holy Scripture*; 2dly, *The proposition that the earth is not the centre of the world, nor immoveable, but that it moves, and also with a diurnal motion, is also absurd, philosophically false, and, theologically considered, at least erroneous in faith.* But whereas being pleased at that time to deal mildly with you, it was decreed in the holy congregation, held before his holiness on the 25th day of February 1616, that his eminence the Lord Cardinal Bellarmine should enjoin you to give up altogether the said false doctrine; if you should refuse, that you should be ordered by the commissary of the holy office to relinquish it, not to teach it to others, nor to defend it, nor ever mention it, and in default of acquiescence that you should be imprisoned; and in execution of this decree, on the following day, at the palace, in presence of his eminence the said Lord Cardinal Bellarmine, after you had been mildly admonished by the said lord cardinal, you were commanded by the acting commissary of the holy office, before a notary and witnesses, to relinquish altogether the said false opinion, and in future neither to defend nor teach it in any manner, neither verbally nor in writing; and upon your promising obedience you were dismissed. And in order that so pernicious a doctrine might be altogether rooted out, nor insinuate itself farther to the heavy detriment of the Catholic truth, a decree emanated from the holy congregation of the index prohi-

It is said that, after having pronounced his abjuration, Galileo, as he rose from the kneeling posture, indignant at the monstrous injustice of his age, stamped on the ground, and said in an under tone, *E pur si muove*, It moves notwithstanding. No doubt it does move, and this is the only answer which those who study nature should at all times make to their detractors and persecutors. What signifies the opinion of men when nature herself speaks? Of what value are their prejudices, or even their wisdom, in opposition to her laws? Why denounce as an impiety the observation of the works of God? Such, indeed, are now the sentiments of persons the most enlightened on the subject of theology; the motion of the earth and the immobility of the sun are no longer contrary to the words of Scripture; it is at length admitted that the Holy Spirit spoke to men in the only language which they could comprehend. It is true that this interpretation, which is now universally received, did not appear good in the time of Galileo, since we have seen that he was himself reprehended for having attempted to give it effect; but, from what we have related of the history of his life, it is evident that the persecution exercised against him was the effect, unhappily too common, of the envy which always attaches to great celebrity. There are arms peculiar to every country. Galileo was a heretic in Italy, as Descartes was an atheist in Holland. However, in denouncing to posterity the shameful injustice done to this great man, it must in fairness be admitted that the formidable tribunal by which he was condemned did not exercise towards him its extreme severity. It has been pretended, without any probability, that he was put to the question. But although it is true that, in the inquisitorial style, this seems to be indicated by the words *rigorosum examen* which are found in the text of the judgment, and although, by a singular coincidence, he began about this time to be afflicted with an intestinal hernia, the ordinary consequence of the particular species of torture (*il tormento della corda*) to which he is supposed to have been subjected; yet, for the honour of humanity, these presump-

---

biting the books which treat of this doctrine; and it was declared false, and altogether contrary to the holy and divine Scripture. And whereas a book has since appeared, published at Florence last year, the title of which showed that you were the author, which title is, *The Dialogue of Galileo Galilei, on the two principal systems of the world, the Ptolemaic and Copernican*; and whereas the holy congregation has heard that, in consequence of the printing of the said book, the false opinion of the earth's motion and stability of the sun is daily gaining ground, the said book has been taken into careful consideration, and in it has been detected a glaring violation of the said order, which had been intimated to you; inasmuch as in this book you have defended the said opinion, already and in your presence condemned; although in the said book you labour with many circumlocutions to induce the belief that it is left by you undecided, and in express terms probable; which is equally a very grave error, since an opinion can in no way be probable which has been already declared and finally determined contrary to the divine Scripture. Therefore by our order you have been cited to this holy office, where, on your examination upon oath, you have acknowledged the said book as written and printed by you. You also confessed that you began to write the said book ten or twelve years ago, after the order aforesaid had been given. Also, that you demanded license to publish it, but without signifying to those who granted you this permission that you had been commanded not to hold, defend, or teach the said doctrine in any manner. You also confessed that the style of the said book was, in many places, so composed that the reader might think the arguments adduced on the false side to be so worded as more effectually to entangle the understanding than to be easily solved, alleging in excuse that you have thus run into an error, foreign (as you say) to your intention, from writing in the form of a dialogue, and in consequence of the natural complacency which every one feels with regard to his own subtilties, and in showing himself more skilful than the generality of mankind in contriving, even in favour of false propositions, ingenious and apparently probable arguments. And, upon a convenient time being given to you for making your defence, you produced a certificate in the handwriting of his eminence the Lord Cardinal Bellarmine, procured as you said by yourself, that you might defend yourself against the calumnies of your enemies, who reported that you had abjured your opinions, and had been punished by the holy office; in which certificate it is declared that you had not abjured, nor had been punished, but merely that the declaration made by his holiness, and promulgated by the holy congregation of the index, had been announced to you, which declares that the opinion of the motion of the earth, and stability of the sun, is contrary to the holy Scriptures, and therefore cannot be held or defended. Wherefore, since no mention is there made of two articles of the order, to wit, the order 'not to teach,' and 'in any manner,' you argued that we ought to believe that, in the lapse of fourteen or sixteen years they had escaped your memory, and that this was also the reason why you were silent as to the order, when you sought permission to publish your book, and that this is said by you not to excuse your error, but that it may be attributed to vain-glorious ambition rather than to malice. But this very certificate, produced on your behalf, has greatly aggravated your offence, since it is therein declared that the said opinion is contrary to the holy Scripture, and yet you have dared to treat of it, to defend it, and to argue that it is probable; nor is there any extenuation in the license artfully and cunningly extorted by you, since you did not intimate the command imposed upon you. But whereas it appeared to us that you had not disclosed the whole truth with regard to your intentions, we thought it necessary to proceed to the rigorous examination of you, in which (without any prejudice to what you had confessed, and which is above detailed against you, with regard to your said intention) you answered like a good Catholic. Therefore, having seen and maturely considered the merits of your cause, with your said confessions and excuses, and every thing else which ought to be seen and considered, we have come to the underwritten final sentence against you. Invoking, therefore, the most holy name of our Lord Jesus Christ, and of his most glorious Virgin Mother Mary, by this our final sentence, which, sitting in council and judgment for the tribunal of the reverend masters of sacred theology, and doctors of both laws, our assessors, we put forth in this writing touching the matters and controversies before us, between the magnificent Charles Sincerus, doctor of both laws, fiscal proctor of this holy office of the one part, and you, Galileo Galilei, an examined and confessed criminal from this present writing now in progress as above of the other part, we pronounce, judge, and declare, that you, the said Galileo, by reason of these things which have been detailed in the course of this writing, and which, as above, you have confessed, have rendered yourself vehemently suspected by this holy office of heresy; that is to say, that you believe and hold the false doctrine, and contrary to the holy and divine Scriptures, namely, that the sun is the centre of the world, and that it does not move from east to west, and that the earth does move, and is not the centre of the world; also that an opinion can be held and supported as probable after it has been declared and finally decreed contrary to the holy Scripture, and consequently that you have incurred all the censures and penalties enjoined and promulgated in the sacred canons, and other general and particular constitutions against delinquents of this description. From which it is our pleasure that you be absolved, provided that, first, with a sincere heart and unfeigned faith, in our presence, you abjure, curse, and detest the said errors and heresies, and every other error and heresy contrary to the Catholic and apostolic church of Rome, in the form now shown to you. But, that your grievous and pernicious error and transgression may not go altogether unpunished, and that you may be made more cautious in future, and may be a warning to others to abstain from delinquencies of this sort, we decree that the book of the Dialogues of Galileo Galilei be prohibited by a public edict, and we condemn you to the formal prison of this holy office, for a period determinable at our pleasure; and, by way of salutary penance, we order you, during the next three years, to recite once a week the seven penitential psalms, reserving to ourselves the power of moderating, commuting, or taking off the whole or part of the said punishment and penance. And so we say, pronounce, and by our sentence declare, decree, and reserve, in this and in every other better form and manner, which lawfully we may and can use. So we, the subscribing cardinals, pronounce. Felix, Cardinal di Ascoli; Guido, Cardinal Bentivoglio; Desiderio, Cardinal di Cremona; Antonio, Cardinal S. Onofrio; Berlingero, Cardinal Gessi; Fabricio, Cardinal Verospi; Martino, Cardinal Ginetti." This document is decisive as to the fallacy of the allegation, that "Galileo was not persecuted as a good astronomer, but only as a bad theologian."

tions seem completely destroyed by the conduct which was subsequently observed towards him. It is certain, from the letters of the ambassador of Tuscany, that he was not thrown into the dungeons of the holy office, although the judgment bears so. The prison assigned him was the lodging of one of the superior officers of the tribunal, with permission to walk throughout the whole palace; he was allowed to retain his domestic; and, so far from being put in solitary confinement, he was permitted to receive the visits of his friends as often as he pleased. All this is established by numerous letters of Galileo himself, dated at this period, and which, fortunately for the cause of truth and humanity, have been preserved. If he did not at once recover his entire liberty, his captivity was at least mitigated as much as it could well be, since the prison assigned him was the magnificent palace of the Archbishop of Sienna, Piccolomini, his friend and pupil, surrounded with beautiful gardens, in which he was allowed to take exercise at pleasure. In the beginning of December 1633, the pope granted him permission to reside openly in the country near Florence; and at a somewhat later period, he was allowed to enter the city as often as his infirmities required. Nevertheless, these restrictions prove that he still remained under the surveillance of the Inquisition; and the Italian writers even say that he several times received, from that tribunal, threatening letters, on account of the pursuits to which he still applied himself, and on pretence of the too intimate connection which he maintained with the learned in Germany.

It was no doubt too much thus to afflict an old man who had committed no other error than that of unfolding truths previously unknown. This treatment made a deep impression on his mind, as may be seen from the preface to his two new dialogues on the motion and resistance of solids, which he confided in manuscript to the Count de Noailles, when the latter was on his return to France from Rome, where he had been ambassador. "Confounded and afflicted with the bad success of my other works," says he, "and having resolved to publish nothing more, I have wished at least to place in sure hands some copy of my works; and as the particular affection with which you have honoured me will certainly make you desirous to preserve them, I have chosen to confide these to you." The count lost no time in communicating them to the Elzevirs, by whom they were printed at Leyden, in 1628, 4to; and it may be presumed that this publication did not occasion Galileo as much uneasiness as his disciple Viviani, writing, like himself, near Rome, would lead us to believe; a presumption confirmed by several letters, addressed to his intimate friends, which have fortunately been preserved. In these two dialogues Galileo created a science altogether new, namely, that of the resistance of solids; and he established, with admirable sagacity, the laws, not less novel, of the accelerated motion of heavy bodies, whether falling freely through space or descending on inclined planes. Nor is this the only production of Galileo which the French have had the honour of saving from his enemies. It was a Frenchman, Father Mersenne, who first published his mechanics; a book which, in a few pages, contains, among other discoveries, a demonstration of the laws of equilibrium on the inclined plane, and that other principle so fruitful in consequences, since called the principle of virtual velocities, which consists in this, that, in any machine whatsoever, the power and the weight in equilibrio are inversely proportional to the spaces which they would pass through in a time infinitely small, if the equilibrium were ever so little disturbed.

Oppressed with the weight of years and misfortunes, Galileo still pursued his observations, and worked with indefatigable courage to continue his tables of Jupiter's satellites, when the loss of sight obliged him, at the age of seventy-four, to discontinue his labours. But his faculties survived this deprivation, and he did not cease to meditate on nature though it was now concealed from his view. Surrounded by attentive and respectful pupils, and by the most distinguished persons of Florence, he lived four years in this state of blindness, after which a slow fever terminated his long and brilliant career, on the 9th of January 1642 (the same year in which Newton was born), at the advanced age of seventy-eight. His body was transported to Florence, and buried in the church of Santa Croce; but it was not until near a century later that the splendid monument was erected which now covers his remains and those of his celebrated pupil and friend Viviani.

The most masterly, and at the same time the most impartial estimate which has yet appeared of the services rendered to the cause of human knowledge by the Florentine philosopher, will be found in the Third Dissertation prefixed to this work (see particularly p. 469, 470), to which the reader is accordingly referred; more especially with respect to the preference which Biot, supported by Hume, has been pleased to assign to Galileo over Bacon in pointing out the true method of studying nature, and showing the art, if it may be so called, of interrogating her by means of experiment. On this subject Professor Playfair has left little or nothing to be said by those who come after him. The accomplishments of Galileo as a scholar were scarcely less remarkable than his discoveries in science. His style, which has been happily characterised by Hume, is so elegant and pure that it has become a classical authority; and we have already shown by what happy preparation he attained this excellence in the art of writing. He loved literature, especially poetry, and was so passionate an admirer of Ariosto that he knew the whole of the Orlando by heart. This predilection indeed he carried so far as to suffer it to betray him into injustice towards Tasso; at least if we may judge from an early composition published after his death, but which he most probably never intended to see the light. But if the manner in which he speaks of the *Jerusalem Delivered* be not always consistent with the respect due to so great a poet, something must at the same time be allowed for that freedom with which the mind gives scope to its own impressions when it converses as it were with itself alone, and is not obliged to observe any of those restraints which publication imposes. It is probable that Galileo would have softened his criticism if he had published it; and it may be believed that when his taste was formed, he would have judged it proper to suppress it entirely; for in several passages of his letters he renders justice to the merit of Tasso, although Ariosto always appeared to him superior as a poet. We have entered into this detail, because an interest attaches to all the distinctive characteristics or peculiarities of celebrated men. For the same reason, we shall add, that Galileo was a man of amiable character and agreeable appearance, particularly in his old age; that his temperament was animated, his manners cheerful, and his conversation attractive; and that he preferred living in the country, where his favourite relaxations consisted in the cultivation of his garden, and in the conversation of his friends. He was never married; but he left three natural children, a son, and two daughters, who, after his death, entered a convent, and took the veil.

Without pretending to give an accurate list of all the works of Galileo, we shall content ourselves with the following enumeration of his principal productions:—1. Nuncius Sidereus, Florence, 1610, in 4to, reprinted the same year at Venice in 4to, and at Frankfort in 8vo; 2. Il Saggiatore, nel quale, con bilancia esquisita e giusta, si ponderano le cose contenute, &c. Rome, 1623, in 4to, being a refutation of the Libra Astronomica of the Jesuit Grassini; 3. Dialogi quattro sopra i due massimi Sistemi del

Mondo, Tolemaïco e Copernicano, Florence, 1632, in 4to, translated into Latin by Bernegger, with other pieces, under the title of Systema Cosmicum; 4. Epistolæ Tres de conciliatione Sacræ Scripturæ cum Systemate Telluris mobilis, quarum duæ posteriores nunc primum cura M. Nevræi prodeunt, Lyons, 1649; 5. Considerazioni al Tasso, printed for the first time in 1793, Venice, in 12mo, and Rome, in 4to; 6. Lettere inedite di Uomini Illustri, published by Fabroni, Florence, 1773, in 8vo, in which are included several unedited letters of Galileo. His treatise on Fortification and Military Architecture is preserved in manuscript in the Bibliotheca Riccardiana, of which Lami published a catalogue in 1756. The editions of his collected works, in which is contained much that was never published separately, are, 1. Opere di Galileo Galilei, Bologna, Charles Manolessi, 1656, in 2 vols. 4to, but very incomplete; 2. Opere, &c., Florence, Bothni, 1718, in 3 vols. 4to, scarcely less so; 3. Opere, &c., Padua, 1744, in 4 vols. 4to, being the first edition of the collected works, containing the Dialogue on the System of the World, after the copy corrected and improved by the author; 4. Opere, &c., Milan, 1811, in 11 vols. 8vo, which is the most complete of all. The most extended life which has yet appeared of this illustrious philosopher is that by Louis Brenna, which has been inserted by Fabroni in the first volume of his *Vitæ Italorum*, 1778. Many precious notices are also to be found in Tiraboschi, and in the work of Targioni-Tozetti on the History of the Sciences in Tuscany. (See *Biographie Universelle*, art. Galileo Galilei, by Biot; *Saggio della Filosofia del Galileo*, by Andrès; and Drinkwater's Life of Galileo, in the *Library of Useful Knowledge.*) (J. B—E.)

GALL, in the animal economy, the same thing as bile. (See ANATOMY.) It was customary among the Jews to give gall or a bitter potion to persons suffering death under the sentence of the law, for the purpose of rendering them less sensible to pain. At our Saviour's crucifixion, according to St Matthew, "They gave him vinegar to drink, mingled with gall"—ὄξος μετὰ χολῆς; whereas in St Mark it is said to be "wine mingled with myrrh."—a very bitter ingredient. It would hence appear that the word χολή was used figuratively, or generally for whatever is exceedingly bitter.

The clarified gall of the ox is employed in the arts for several purposes. It is used by the scourers of clothes to remove spots of grease; and by painters in water-colours.

GALL or GALL-NUT (Lat. *galla*). Gall-nuts are excrescences which are formed on the *Quercus infectoria*, a species of oak that abounds in Asia Minor, Syria, Persia, &c., and on some others. They are produced by the attacks of the cynips, a small insect which deposits its eggs in the tender shoots of the tree; and when the maggot is hatched, it occasions a morbid excrescence of the surrounding parts. Galls are inodorous, and have a nauseously bitter and astringent taste. They are nearly spherical, and vary in magnitude from the size of a pea to that of a hazel-nut. When good, they are of a black or deep olive colour, and the surface is tubercular. In commerce they are distinguished into *white*, *green*, and *blue* galls. The two latter kinds are the best. The chief products of galls are tannin and gallic acid. Galls are very extensively used in dyeing, and in the manufacture of ink. (See DYEING.) They are the most powerful of all the vegetable astringents, and are frequently used in medicine. Galls are chiefly imported from Aleppo, Tripoli, Smyrna, and Said. It is not unusual to dye the white or inferior kind blue, in order to increase their value; but this fraud is easily detected by their being perforated, and lighter than the genuine blue galls. (M'Culloch's *Dict. of Com.*) The term *gall* is also applied generally to any protuberance or tumour produced on trees by the puncture of insects.

GALL OF GLASS, called also *sandiver*, is the neutral salt skimmed off the surface of crown-glass in the melting pots.

GALL, FRANCIS JOSEPH, the founder of Phrenology, as it is now called, was descended of a respectable family residing at Tiefenbrunn, two leagues distant from Pforzheim, in Suabia, and born on the 9th of March 1757. His father was a shopkeeper or merchant, and mayor of the village. His parents, who were of the Roman Catholic persuasion, originally intended him for holy orders; but his natural dispositions were adverse to such a destination. He pursued his studies first at Baden, then at Brucksal, and afterwards at Strasburg, where he completed his literary education. Having resolved to study medicine with a view to the practice of physic, he, in 1781, proceeded to Vienna, the medical school of that capital having acquired great celebrity, particularly since the times of Van Swieten and Stoll; and, after passing through the ordinary course, he took his degree.

Being early given to observation, Gall, whilst yet a boy, was struck with the fact, that each of his companions and schoolfellows possessed some peculiarity of talent which distinguished him from the others. One excelled in penmanship, another in arithmetic, a third in the acquisition of languages. The compositions of some were remarkable for elegance, whilst those of others were hard, stiff, formal, and dry; several connected their reasonings in the closest manner, and clothed their arguments in forcible language; many were devoid of the talent for logical arrangement, and incapable of expressing themselves with clearness and precision. Nor were their dispositions less various than their intellectual endowments. Not a few manifested a capacity for employments which they had not been taught, such as cutting figures in wood, or delineating them on paper; some devoted their leisure to drawing or gardening, whilst others abandoned themselves to noisy games, or traversed the woods to gather flowers, search for birds' nests, or catch butterflies. In short, each presented a character peculiar to himself, and Gall did not observe that the individual who, one year, displayed selfish or knavish propensities, became a kind and faithful friend the next. Of his schoolfellows, those with whom he experienced the greatest difficulty in competing, were the boys who committed their lessons to memory with the greatest facility; and such individuals frequently gained from him by their repetitions the places which he had obtained by the merit of his original compositions. Several years afterwards, having changed his place of residence, and still meeting with individuals possessed of the same faculty, he observed that the individuals so gifted had all prominent eyes, and he also recollected that his rivals in the first school had been distinguished by the same peculiarity. On entering the university, he accordingly directed his attention to those students who had large eyes, and, upon inquiry, he found that they all excelled in committing pieces to memory and giving correct recitations, although many of them were by no means remarkable for general talent. As the coincidence thus observed was recognised by the other students in the classes, Gall conceived that it could not be entirely accidental; and hence, from this period, he seems to have come to the conclusion that they stood in an important relation to each other. But if verbal memory was thus indicated by an external sign, it required no great effort of generalization to conceive that the other intellectual powers might have each its appropriate manifestation. Proceeding on this idea or assumption, Gall now directed his attention to individuals distinguished by any remarkable faculty; and, after a course of observation, he conceived himself to have discovered and defined the external characteristics indicative of decided talents for painting, music, and the mechanical arts. Having also become acquainted with several persons remarkable for determination of character, he observed that a particular part of their heads was largely developed, and this development he set down as the external sign or manifestation of the character referred to.

His next step was to look in the head for the indications of the moral sentiments as well as of the intellectual faculties; but here he experienced considerable difficulties. Hitherto he had been ignorant of the opinions of physiologists concerning the brain, and of metaphysicians respecting the mental faculties; and, on turning to books, he became so much perplexed by the discordance of the views therein inculcated, that, for a time, he hesitated as to the correctness of his own observations. He found that, whilst Pythagoras, Plato, Galen, Haller, and others, placed the sentient soul in the brain, Aristotle fixed its residence in the heart, Van Helmont in the stomach, Descartes in the pineal gland, and Drelincourt in the cerebellum; that, according to many philosophers and physiologists, all men are born with equal mental faculties; and that the differences observable amongst mankind are not ascribable to any original or constitutional inequality of powers, but the result partly of education, and partly of the diversified circumstances in which individuals are placed. But if all differences are accidental, it is evident that there can be no natural signs of predominating faculties, and, consequently, that the project of attempting, by observation, to discover the functions of the different portions of the brain, must be abandoned as hopeless. Sensible of this, Gall combated the difficulty by denying the truth of the doctrine of original equality on which it is founded. He contended that persons who have all received the same or very nearly the same education unfold each a distinct character, over which circumstances appear to exercise only a limited control; that individuals, whose education has been conducted with the greatest care, and on whom the labours of instructors have been most freely lavished, frequently remain far behind their companions in attainments; that many, even with the most ardent desire, followed out by the most persevering efforts, cannot, in some pursuits, attain even to mediocrity; that, in point of fact, instructors of youth do not appear to attach much faith to the system which teaches the equality of mental faculties, and think themselves entitled to exact more from one scholar and less from another; that the doctrine of Scripture, according to which, each will be required to render an account only in proportion to the gifts which he has received, serves to confirm this view, and is, moreover, in accordance with observation and experience. On these grounds, Dr Gall concluded that there is a natural and constitutional diversity of talents and dispositions amongst men; and that, supposing the exercise of the mental faculties dependent on the functions of the brain, the external signs of these faculties may be determined by observation.

Abandoning every theory and preconceived opinion, therefore, he applied himself to the discovery of those signs of the existence of which he had thus satisfied his own mind. Being physician to a lunatic asylum at Vienna, he had opportunities of making observations on the insane; he visited prisons, and resorted to the seats of learning; he was introduced to the courts of princes and the tribunals of justice; wherever he heard of an individual remarkable either for his mental endowments or defects, he studied the development of his head; and at length he conceived himself warranted in maintaining that particular mental powers are indicated by particular configurations of the shell or case in which the brain is lodged. Hitherto he had resorted only to physiognomical indications in order to discover the functions of the brain; but, being convinced that physiology is imperfect when separated from anatomy, he felt the necessity of instituting anatomical researches into the structure of the brain.[1] Accordingly, in every instance where an individual whose head he had examined whilst alive happened to die, he used every means to obtain permission to examine the brain, and frequently did so; and he states it as a general fact, that, on the skull being removed, the brain, covered by the dura mater, presented a form corresponding to that which the skull had exhibited in life. Thus, by successive steps, by first observing a concomitance between particular talents and dispositions, and particular forms of the head, and next by ascertaining that the figure and size of the brain were indicated by these external forms, Dr Gall conceived that he had determined the intellectual dispositions corresponding to about twenty organs, or, in other words, ascertained the residences of as many intellectual faculties of the first order; and these organs he named according to the faculty or propensity which he attributed to each respectively. In short, he maintained that the intellectual dispositions being innate, have their seats in the brain, where the organs of the faculties are also situated; that the more prominent any isolated point on the skull is, the greater is the activity of the faculty, the organ of which is there placed; and that the part of the brain where such faculty resides and acts, by pressing on the skull, forms, on its convex surface, a protuberance, which indicates externally the organ, and is, in fact, its invariable sign.

Dr Gall first became known as an author by the publication of two chapters of a work entitled *Philosophisch-Meicinishe Untersuchungen über Natur und Kunst im gesunden und krauken Zustande des Menschen*, Vienna, 1791. This work was not continued; but in the two chapters published, Dr Gall evinced the spirit which subsequently guided his researches into the intellectual and moral nature of man. The first written notice of his inquiries respecting the differences of form observable in the human head was contained in a familiar letter addressed to Baron Retzen, which appeared in the *Deutschen Mercur* of December 1798; but two years before this Dr Gall had commenced giving courses of private lectures at Vienna, where his doctrines soon attracted general attention; and Froriep, Martens, and Walther, were among his hearers. He continued his lectures for five years, with increasing success, when, at length, upon the 8th of January 1802, the Austrian government issued an order, interdicting them, on the ground that the doctrines therein promulgated were dangerous to religion; and, in a general regulation which accompanied the order, all private lectures were prohibited, unless specially permitted by the public authorities. Dr Gall understood the object of this regulation, and never solicited permission; but, as usually happens, the prohibition stimulated curiosity, and the doctrines thus interdicted were studied with greater zeal than before. It is difficult to perceive what object the Austrian government proposed to attain by this foolish interposition, more especially as publications on the subject continued to be permitted, provided they abstained from reflecting on the government for issuing the order above mentioned. On the 6th March 1805, Dr Gall left Vienna, in company with Dr Spurzheim, whom he had now associated with him in his pursuits, and proceeded to Berlin, where he remained a short time; he then visited all the principal towns and universities of Germany, and in November 1807 repaired to Paris, where he established himself as a medical practitioner, and remained till the time of his death. To the charge of Spinozism or atheism, which was strongly urged against him, particularly by some of the French scholars, Dr Gall replied in a work entitled *Des Dispositions innées de l'Ame et de l'Esprit, ou du Matérialisme,* Paris, 1812, in 8vo, which he seems to have intended as an authoritative exposition of the metaphysics of the new science. But a much ruder onset awaited it. In 1815, and again in 1826, craniology was attacked in able articles inserted in the *Edinburgh Review,* where the united powers of argument and ridicule were forcibly directed against it by writers possessing an equal mastery over both; but the results of Dr Gall's observations were not, in the opinion of his followers, destroyed, nor even materially affected, by the critical severity with which these had been examined in the Review; and their confidence in the truth of the system, which to the uninitiated appeared to be overthrown, gained strength from each successive shock to which it was exposed. But whatever may be thought of Dr Gall's discoveries, either in reference to the philosophy of mind, or to the moral and religious opinions of mankind, it seems to be pretty generally conceded, that, by his dissections and observations, he has considerably advanced the knowledge of the cerebral system, and that, even if he be accounted a bad philosopher, he has at least shown himself an able anatomist. He demonstrated, what before was only conjectured, that cerebral matter does not derive its origin from the brain, but from the spinal marrow; which, expanding as it proceeds, at length forms the two hemispheres into which the brain is divided. In conjunction with Spurzheim, Dr Gall published at Paris, in 1810, *Anatomie et Physiologie du Système nerveux en général, et du Cerveau en particulier;* but of this work there only appeared a volume and a half. The most elaborate of his productions, however, is *Organologie, ou Expositions des Instincts Penchans, &c. et du siège de leurs Organes,* which was completed in 1825. His *Histoire des Fonctions du Cerveau* had appeared in 1822, in two vols. 8vo. In 1828 Dr Gall died at Paris, where he had for many years practised medicine with success, leaving his mantle to Dr Spurzheim, who had been long associated with him both in the pursuit and the propagandism of phrenology. (See *Biographie des Hommes Vivants,* art. Gall; and *Transactions of the Phrenological Society,* Edinburgh, 1824; *Nécrologie,* 1828; *Edinburgh Review,* vols. xxv. and xlv.) (J. B—E.)

---

[1] Having observed a woman, aged fifty-four years, who from her youth had been afflicted with water in the head, yet possessed a mind as active and intelligent as that of any other individual of her class, Dr Gall declared his conviction that the structure of the brain must be different from what it was generally supposed to be; a conclusion which Tulpius had already drawn from observing a hydrocephalic patient, whose mental faculties remained unaffected by the disease under which he was labouring. This, and other analogous cases, convinced Dr Gall of the necessity of instituting minute anatomical researches into the structure and functions of the brain.

GALL, St (German *Sankt Gallen*), a canton in the N.E. of Switzerland, occupying the fourteenth place in the Swiss confederation, and bounded on the N. by the canton of Thurgau and the lake of Constance, E. by the Rhine, which separates it from Tyrol and the principality of Liechtenstein, S. by the cantons of Grisons and Glarus, and W. by those of Schwyz and Zürich. Area 753 square miles. This canton was formed in 1798, by the union of the territories of the abbot of St Gall with the free town of St Gall, and several districts previously subject to the older cantons. As these all lay around the canton of Appenzell, that canton is wholly surrounded by the canton of St Gall. The surface is greatly diversified, and for the most part mountainous, particularly in the south, where it is almost wholly covered with Alpine ranges. The summits of some of these rise to the height of 7000 or 8000 feet, and Mount Scheibe at the S.W. extremity has an elevation of about 9000 feet. These mountain ranges inclose some extensive and fertile valleys, the principal of which are those of the Rhine and Toggenburg. Besides the Rhine, the principal rivers of this canton are the Thur, Sitter, Seez, Linth, and Tamina. St Gall includes parts of the lakes of Constance and Zürich, and the greater portion of that of Wallenstadt. The plains and valleys are in many parts well cultivated, but the produce of corn is not equal to the wants of the inhabitants. Potatoes are extensively grown, and fruits of various kinds are raised in large quantities, especially apples, from which cider, the common drink of the people, is made. Some wine is also made; and *kirschwasser* (cherry-water) is an important product of the mountainous parts of the canton. The country being generally better adapted for pasturage than tillage, the rearing of cattle constitutes the chief branch of rural industry. The forests in the south are extensive, and consist chiefly of pine and fir trees. Coal and turf are found in several districts, and iron mines are wrought in one or two places. Mineral springs are numerous,—the most celebrated being those of the Pfeffers. Manufactures constitute an important branch of industry in this canton. Its capital, St Gall, was long celebrated for its linen manufactures, but these have been in a great measure replaced by the manufacture of cotton goods, especially muslins. Cotton goods are also largely manufactured in the valley of Toggenburg and other places. The women are much employed in embroidery. There are numerous bleaching establishments, glass-works, and wax-bleaching factories; but the manufactures have generally decreased since the peace. The imports are chiefly corn and other provisions, and raw materials for the manufactures; and the chief exports are manufactured goods, cattle, and hides. The government is one of the most democratic in Switzerland. It consists of a great and a little council. The former is composed of 150 members chosen in the different districts, by citizens above 21 years of age, who hold office for two years. The little council or executive consists of seven members, chosen by the great council from among its own members, and holding office for four years. The people enjoy the right of a *veto* on any law passed by the councils, within 35 days of the time of its passing. The canton of St Gall returns eight members to the national council. The language of the people is a dialect of the German, resembling the Suabian. St Gall is the only town of importance in this canton,—none of the others having a population of above 2500 inhabitants. Pop. (1851) 169,625, of whom 105,370 were Catholics, 64,192 Calvinists, and the remainder chiefly Jews.

Gall, St, the capital of the above canton, is situated in an elevated valley on the Steinach, 7 miles S.W. of the lake of Constance. It is a well-built town, surrounded by old walls, but the ditch has been filled up and converted into gardens. Among its public buildings may be noticed the cathedral, formerly the abbey church; an orphan asylum outside the walls; the assembly-rooms; and the townhouse. It has also a Catholic and a Protestant gymnasium, several learned and benevolent societies, natural history collections, a public library, &c. The Catholic gymnasium occupies the abbey buildings, and the abbot's palace is now used for public offices. This is one of the principal manufacturing towns of Switzerland. Its manufactures are chiefly muslins and other cotton goods; and in the town and vicinity are numerous bleaching establishments. This town is said to have taken its rise from a cell founded here in the early part of the seventh century by St Gallus, a monk from Iona. Fifty years after his death was erected, under the auspices of Pepin l'Heristhal, an abbey, which between the eighth and tenth centuries was one of the most celebrated schools in Europe. About the end of the tenth century the abbey buildings were fortified, and subsequently the abbots obtained possession of considerable territory, and became princes of the empire. Early in the fifteenth century Appenzell threw off the yoke of the abbot, and the town of St Gall acquired its independence at the Reformation. The abbey was secularized after the French Revolution, and in 1805 its revenues were sequestrated. Pop. (1850) 11,234, chiefly Protestant.

Galland.

Gallas ‖ Gallia.

GALLAND, Antoine, a celebrated orientalist and numismatist, was born in 1646, at Rollat, near Montdidier in Picardy. His father died when he was a mere child; but his mother contrived to place him in the college of Noyon, where he was carefully educated. After leaving this establishment he had to contend with many difficulties and hardships, arising from the poverty of his family; but he manfully continued to prosecute his oriental studies, till in 1670 he was attached to the French embassy at Constantinople. His special duty was to procure from the Greek churches formal attestations of the articles of their faith, which then formed the subject of a grand controversy between Arnauld and Claude. He also accompanied the French ambassador to Jerusalem, and availed himself of the opportunity to copy a great number of inscriptions, and even to remove them, as often as he found it practicable to do so. Of these, Montfaucon has published some fragments in his *Palæographia Græca*. From Syria Galland returned directly to France, whence he immediately set out again for the Levant with the intention of collecting medals. In 1679 he undertook a third voyage, being charged by the India Company to collect everything calculated to enrich the cabinet of Colbert; but this commission having ceased in consequence of changes which took place in the company, Colbert, and, after his death, Louvois, instructed Galland to continue his researches, and caused the title of "antiquary to the king" to be conferred on him. On his return to Paris, Thevenot, keeper of the king's library, and D'Herbelot, the celebrated oriental scholar, availed themselves of his labours. After their death he attached himself to Bignon, and finally to Foucault, intendant of Lower Normandy, who received Galland into his house, where, in the midst of a fine library, and a numerous collection of medals, he applied himself to the composition of different works, in which he turned to account his knowledge of the Arabic, Persian, and Turkish languages, with which he had rendered himself familiar during his residence in the east. In 1701 he was admitted into the Academy of Inscriptions, although he resided at Caen. In 1706 he returned to take up his habitation in Paris; and three years afterwards he obtained the chair of Arabic in the Royal College of France. This learned man terminated his laborious, useful, and irreproachable life on the 17th of February 1715, at the age of sixty-nine.

The following is a list of his printed works:—1. Trois Lettres touchant la critique de M. Guillet, sur le Voyage de Grèce de Spon, printed in the reply of Spon, Lyons, 1679, in 12mo; 2. Paroles remarquables, bons mots, et maximes des Orientaux, traduits de leurs ouvrages Arabes, Persans, et Turcs, avec des remarques, Paris, 1694, in 12mo; 3. Lettres touchant l'Histoire des quatre Gordiens, prouvée par les Médailles, Paris, 1696, in 12mo; 4. Lettre touchant quatre médailles antiques, publiées par le P. Chamillard, Caen, 1697, in 12mo; 5. Lettre touchant la nouvelle explication d'une médaille d'or du cabinet du Roi, Caen, 1698, in 12mo; 6. Lettre sur le même sujet, printed in the Journal des Savants, 15th August 1705; 7. Observations sur quelques médailles de Tétricus le père, et d'autres tirées du cabinet de M. Ballonseaux, Caen, 1701, in 8vo; 8. De l'origine et du progrès du Caffé, translated from an Arabic manuscript in the library of the king, Caen, 1699, in 12mo; 9. Les Mille et Une Nuits, contes Arabes, traduits en Français, Paris, in 12 vols. 12mo: Relation de la Mort du Sultan Osman, et du couronnement du Sultan Mustapha, translated from the Turkish, Paris, 1678, in 12mo; 11. Several articles in the Journal de Trévoux; 12. Letters written from Smyrna and Constantinople; 13. Contributions to the Menagiana, as well as to the Bibliothèque Orientale of D'Herbelot, who died before the printing of the work was completed; 14. Ten dissertations and memoirs for the collection of the Academy of which he was a member. Since the death of Galland there have been published of his, 1. Contes et Fables Indiènnes de Pidpaï et de Lokmann, Paris, 1724, in 12mo; 2. Dissertation sur une médaille Grecque de l'Empereur Diaduménien, frappée à Ephèse, 1739; 3. Relation de l'esclavage d'un Marchand Français de la ville de Cassis à Tunis, 1809. The manuscripts left by Galland were, 1. Histoire des Princes de la lignée de Tamerlan, depuis le Sultan Abou-Saïd-Bahadur, jusqu'au Sultan Abou-Saïd-Kourkan; 2. Histoire Othomane, traduite du Turc de Naïma Effendi; 3. Vocabularium Turkico-Latinum; 4. A translation of the History of Djenguyz-Khan, extracted from the Persian History of Mirkhoud; 5. Catalogue d'écrivains Arabes, Persans, et Turcs; 6. Journal de mon séjour à Constantinople pendant l'année 1672 et 1673; 7. Dictionnaire Numismatique; 8. Relation de ses Voyages; 9. Traduction de l'Alcoran; 10. Nécrologie de la mort des Savants pour chaque jour de l'année de 1500 à 1701; 11. Relation d'un Voyage fait à Constantinople en 1679 et 1680; 12. Etat present des îles de Samos, de Nicaire, de Patmos, et du Mont Athos; 13. Description de la Ville de Constantinople en 1671 et 1672; 14. Relation des Evénemens qui se sont passés à Constantinople en 1671 et 1672. (J. B—E.)

GALLAS, a rude and savage people of Africa, who have overrun the greater part of Abyssinia from the south. See Abyssinia, and Africa.

GALLEGO, a river of Spain, in the province of Aragon. It rises in the valley of Tena, among the Pyrenees, on the mutual boundary between France and Spain, in a large fountain near Tormigal. After a course of about 100 miles it falls into the Ebro a mile below Zaragoza.

GALLEGOS, San Felices de los, a secular town of Spain, in the province of Salamanca. It contains 2000 inhabitants, and is situated 25 miles from Ciudad Roderigo, in a plain encompassed with hills, abounding in springs of excellent water and mineral wells. About six miles west of it flows the river Agueda, crossed by an excellent bridge. The industrial occupations of the inhabitants are chiefly the manufacture of oil, wine, and linseed for domestic use.

GALLEON, the name given by the Spaniards to a very large kind of ship with three or four decks, such as those formerly employed by them to transport the precious metals from the mines of Mexico and Peru.

GALLEOT, or Galliot, a small galley or large felucca, used chiefly in the Mediterranean. Galliot also denotes a peculiar kind of flat-bottomed vessel, very strongly timbered, used as a bomb-ship against forts and batteries. *Bomb-ketch* is likewise applied by the Dutch, Swedes, and other northern nations, to a strong-built trading vessel, rounded at stem and stern, and registering from 200 to 300 tons.

GALLERY, in *Fortification*, an underground passage, either cut through the soil or built of masonry. Galleries (reverse) or *niches* are sometimes constructed in the counterscarp of a ditch, so as to afford a flanking musketry fire. They are closed in front, and the men fire through loopholes.

Gallery, in the *Fine Arts*, see Exhibition.

GALLEY, a low-built long and narrow vessel, with one deck, propelled by oars and sails, and much used in the Mediterranean previous to the introduction of steamboats. Galleys of the largest size were about 166 feet by 32 in breadth, with 26 or more pairs of oars. The rowers were usually either convicts or Turkish prisoners, who were chained to the benches on which they sat. The word *galley* is from the Latin *galea*, a helmet—a designation said to be derived from a kind of basket-work at the mast-head of the vessel.

GALLI, in *Antiquity*, a name given to the priests of Cybele, and said to be derived from the river Gallus in Phrygia. See Corybantes, and Curetes.

GALLIA, in English Gaul, the country inhabited by the Galli. By the Romans the term "Gallia" was restricted in its use to those portions of Europe occupied by tribes of the Gallic name. In classical times these fell naturally into two great divisions, the one lying on the southern or Roman side of the Alps, and thence called "Gallia Cisalpina;" and the other on the northern or further side of that mountain-range, and thence called "Gallia Transalpina." Transalpine Gaul, as understood by Cæsar, comprised the whole of France and Belgium, a small part of the Netherlands, Luxemburg, Germany west of the Rhine, the greater part of Switzerland, and a part of Savoy. This country, the entire area of which was about 240,000 square miles, was bounded on the east and north-east by the Alps, extending from Genoa to Mont St Gothard, and the Rhine from its source to the sea. On the south it extended along the Mediterranean from the small river Varus (the Var), which separated it from Italy, to a short distance beyond Portus Veneris (Bellegarde), at the eastern extremity of the Pyrenees, which mountain-range separated it from Spain. The western and northern shores of Gaul were washed by the ocean.

Gallia Cisalpina extended southwards from the Alps to the confines of Etruria and Umbria. Only a small portion of this country, however, was occupied by tribes of Gallic origin, but the Romans who had at first employed the term in a somewhat vague sense to northern Italy, ended by applying it to the basin of the Po and the Alpine country north of that river, so far as it had been subdued by them. The Inalpini, or tribes that dwelt within the Alps, were not finally subdued till the times of Augustus.

The most important of the tribes inhabiting both the Gauls will be found described under their respective heads.

GALLIC ACID. See Dyeing, vol. viii. p. 281.

GALLICISM, an idiom of the French language employed in an expression, or in the construction of a sentence belonging to another language.

GALLIENUS, P. Licinius, emperor of Rome from 253 to 268 A.D. In the beginning of his reign he gave proof both of bravery and ability in his defeat of the barbarians who had invaded Italy from the north. He afterwards belied the promise of his youth, and gave himself up to excess and debauchery of every kind. Usurpers soon appeared in almost every province of the empire, and this period of Roman history came to be called the reign of the thirty tyrants. Gallienus was killed at Milan while besieging one of his refractory vassals in that city.

GALLIPOLI, anciently *Callipolis*, an important seaport town of Naples, province of Terra di Otranto, beautifully situated on a rocky islet, on the east shore of the Gulf of Taranto, and connected by a long stone bridge of twelve arches with the mainland, on which is its suburb of Lizza. The town is well-built and fortified, and has a castle erected by Charles I. of Anjou, a cathedral, and a fountain decorated by antique bas-reliefs. It is chiefly noted for its extensive cisterns cut in the solid rock for containing the olive oil collected from all parts of Puglia, and which constitutes its chief export. It has no harbour, but a bay or roadstead north-east of the town, with from ten to twelve fathoms water, but trending towards the shore so that vessels of considerable burden should not come within less than a musket shot of the land. Gallipoli has also a considerable trade in corn, fruits, &c., and a productive tunny fishery. The chief manufactures are muslins, cotton stockings, and woollen goods. Pop. upwards of 10,000.

Gallipoli, anciently *Callipolis*, a seaport town of European Turkey, province of Rumilia, on the northern shore of the Hellespont, at the entrance to the sea of Marmora, 90 miles south of Adrianople. It is situated on a peninsula, and protected by two ports, and is one of the chief stations of the Turkish fleet. Its trade is chiefly in corn, wine, and oil, and it has several extensive and well-furnished bazaars. The chief manufactures are cottons, silks, earthenware, and Morocco leather, which last is the best made in Turkey. It is the see of a bishop of the Greek Church. The houses are mean, and the streets narrow and dirty. It was once fortified, but its walls have been destroyed, and its only defence is now an old square castle with a tower, built probably by Bajazet. On the south side of the town are some tumuli, said to be the sepulchres of the ancient Thracian kings, and on the north are some undefined ruins, supposed to be the remains of the ancient city. Fragments of sculpture and architecture are to be seen in all parts of the town. A considerable improvement was effected here by the allied troops in 1854. Pop. probably about 20,000, including Turks, Armenians, Jews, and some Greeks.

GALLOIS, Jean, one of the founders of the *Journal des Savans*, was born at Paris on the 11th of June 1632. From his infancy he evinced a strong inclination for learning, which his father, an advocate in the parliament, cultivated with the greatest care. Having entered the ecclesiastical state, he turned his studies towards theology, and at the same time endeavoured to perfect himself in the knowledge of Greek and of Hebrew, that he might be able to read the sacred books in the originals; he also devoted his leisure hours to literature and the sciences; and as he was endowed with an excellent memory, as well as a sound judgment, his different acquisitions arranged themselves without confusion or disorder in his mind. To learning equally solid and various he joined the talent, then rare among scholars, of writing his vernacular with precision and elegance; and hence no one could be better qualified than he for conducting a work having for its object to make known the literary and scientific productions of other nations. Such was the object of the *Journal des Savans;* and as the privilege had been withdrawn from Sallo, on the complaints of some writers whom he had censured with too great bitterness, Colbert bestowed it on the Abbé Gallois in 1666. The latter had the sole charge of this journal till 1674, when the amount of labour which it imposed, with his other avocations, forced him to abandon it altogether. Colbert, who had appreciated the merit of Gallois, gave him at first an apartment in his hôtel, and afterwards, during his journeys to Versailles, intrusted it entirely to his care. It has been alleged that this minister desired to learn Latin, and that he retained the Abbé Gallois for the purpose of instructing him in that language. It is believed that Gallois furnished the plan of the Academy of Inscriptions, although he did not become a member; but he had been admitted into the Academy of Sciences in 1668, and in 1673 he filled the place of Bourzéis in the French Academy, being admitted the same day with Fléchier and Racine. After the death of his illustrious protector, he obtained the place of keeper of the king's library; and, some years afterwards, when he lost this situation, he was, by way of compensation, appointed professor of the Greek language in the Royal College. After the remodelling of the Academy of Sciences, he was placed in the class of geometry; and he then proposed to publish the treatise of Pappus, of which there only existed a defective Latin translation; but this design was not carried into execution. The Abbé Gallois died on the 19th of April 1707, in the seventy-fifth year of his age. Notwithstanding the extreme mediocrity of his fortune, he had collected more than twelve thousand choice volumes, a catalogue of which was printed in 1710. Besides his contributions to the *Journal des Savans*, the Abbé Gallois wrote, 1. Traduction Latine du Traité de Paix des Pyrenées, Paris, 1659, in fol.; 2. Remarques sur le projet de l'Histoire de France, dressé par Ducange, printed in the new edition of the *Bibliothèque Historique de France*, tome iii.; 3. Réponse à l'écrit de David Gregory, touchant les lignes appelées Robervalliènes, qui servent à transformer les figures, Mém. de l'Acad. des Sciences, 1692; with some others of less note. The éloge of Gallois was pronounced by Fontenelle. (J. B—E.)

GALLON, a measure of capacity both for dry and liquid articles, containing four quarts.

GALLOON, a rich kind of lace made of gold or silver, or of silk only.

GALLOWAY, a district of Scotland comprehending the stewartry of Kirkcudbright and Wigtonshire. See Kirkcudbright, and Wigtonshire.

Galloway, *Mull of.* See Wigtonshire.

Galloway, *New*, a royal and parliamentary burgh of Scotland, stewartry of Kirkcudbright, on the Ken, 19 miles

N. of Kirkcudbright. It unites with Wigton, Stranraer, and Whithorn in returning a member to parliament, and is governed by a provost and eighteen councillors. Loch Ken and Kenmure castle are in the vicinity. Pop. (1851) 447.

GALLOWAY, Thomas, a distinguished Scottish mathematician, was born at Symington in the upper ward of Lanarkshire, 26th February 1796. After receiving such education as the best schools of his own and some adjoining parishes could give, he removed in 1812 to Edinburgh, at the university of which city he distinguished himself, especially in the department of mathematical study. In 1823 he was appointed one of the teachers of mathematics at the military college of Sandhurst. On the death of Sir John Leslie in 1832, Galloway applied for the vacant chair of natural philosophy in Edinburgh, and was one of the three candidates among whom the chances of success ultimately lay. He was not the successful competitor; but in the following year was appointed actuary to the Amicable Life Assurance Office, the oldest institution of that kind in London. In this situation Galloway remained till his death, November 1, 1851.

Galloway was a voluminous though for the most part an anonymous writer, and took a leading part in the proceedings of the principal scientific societies of London. He contributed largely to the *Encyclopædia Britannica*, and other works of a similar nature. Some of his more elaborate treatises, such as that on *Probability*, have been published separately. His contributions to the *Edinburgh* and *Foreign Quarterly Reviews*, like the rest of his writings, display extensive erudition, great soundness of judgment, and fine powers of critical analysis.

GALLS. See Gall.

GALLUS, C. Cornelius, a distinguished Roman poet, orator, and politician. He was born of humble parents at Forum Julii (Fréjus) in Gaul, about the year 66 B.C. At an early age he removed to Rome, where he was taught by the same master as Virgil and Varius, with both of whom he afterwards lived on terms of the most intimate friendship. In political life he espoused the cause of Octavianus; and in reward for his services was made first prefect of Egypt. His good fortune, however, turned his head, and urged him to a course of conduct which brought him into disgrace with Augustus. The accusations of arrogance, extortion, and even cruelty, brought against him were so numerous and well supported, that Gallus, in order to escape exposure, put an end to his life by throwing himself on his sword, B.C. 26 years.

Gallus enjoyed a high reputation among his contemporaries as a man of intellect. He associated on terms of equality with all the literary notabilities of his day, Virgil, Ovid, Varius, Asinius Pollio, and others. He wrote four books of elegies, which were so good that Ovid claimed for their author the first place among the elegiac poets of Rome. His fame as an orator was hardly inferior to his renown as a poet; but as not a fragment of his composition has descended to our times, we have no means of judging the worth of his literary pretensions, and have to content ourselves with the somewhat partial estimate of his personal friends.

GALSTON, a small market-town of Ayrshire, on the left bank of the Irvine, and on the South-Western Railway, 22 miles S. by W. of Glasgow. Pop. (1851) 2538, chiefly cotton weavers.

GALT, John, a popular Scottish novelist, born in 1779 at Irvine in Ayrshire—a small town that enjoys the triple literary distinction of having been the birth-place of Galt and James Montgomery, and the residence of Burns during an interesting portion of his early career. From the same place, too, Galt derived the prototypes of some of his best Scottish characters. Having received his education at Greenock, and acquired a knowledge of mercantile affairs, Galt proceeded to London to push his fortune. He was unsuccessful in a partnership scheme, and afterwards entered himself of Lincoln's Inn, intending to study the law. He was tempted abroad, however, partly by delicate health and partly to carry out some mercantile speculations. At Gibraltar he met with Lord Byron and Mr Hobhouse, and sailed in the same packet with them to Sardinia and Malta. This accidental acquaintance, which was afterwards slightly renewed, led Galt to write a life of Byron after the decease of the noble poet, but the work did not add to his reputation. After three years' residence and wanderings in Sicily, Greece, and Turkey, during which he was engaged in several commercial enterprises of importance, though not of profit, Mr Galt returned to England, published his travels, and entered on what may be called a professional literary life. A Scottish tale, *The Ayrshire Legatees*, published in *Blackwood's Magazine*, was highly popular; and this was followed by a series of works of a similar character—*The Annals of the Parish*, *The Provost*, *The Steam-Boat*, *Sir Andrew Wylie*, *The Entail*, and *The Last of the Lairds*. In these novels Galt opened up views of Scottish life and character scarcely touched upon by Scott, yet as true to nature as the portraits of that great master. They were types of classes fast disappearing—old-fashioned ministers, magistrates, and lairds, whose oddities are portrayed in lively colours, interspersed with scenes of genuine pathos and winning simplicity. Another charm in these works was their rich and copious Scottish diction—the fine old quaint Doric, so simple yet figurative and expressive—which is now rarely heard in the same unsophisticated purity and force even among the village elders. The *Annals of the Parish* stands at the head of these works, and there is little hazard in predicting that it will form Galt's best passport to a durable fame. He wrote many other novels, several plays and poems, the life of Cardinal Wolsey, and that of Benjamin West the artist. No author was ever more unequal than Galt—extravagant improbable fictions followed some of his happiest creations, and much of what he published must be considered as mere task-work written to meet the exigencies of the day. In one other novel he was eminently successful. He was appointed agent for the Canada Land Company, and was placed among the woods and wildernesses of the new world, and amidst settlers and squatters of various descriptions. New phases of life and strange adventures were thus brought before him, and he embodied his observations in a tale entitled *Lawrie Todd*, founded on the real experiences of a pawky Scottish emigrant. This is a powerful and interesting work, resembling the fictions of De Foe in its life-like reality and teeming variety of incidents. The latter years of this ingenious writer were clouded by poverty and disease. All his splendid commercial and trading schemes had failed, his inventions, like those of most inveterate projectors, brought him only trouble or disappointment, and though his mind and pen were still as facile and ready as ever, he had exhausted his fine original vein, and had to contend with confirmed ill-health. Repeated attacks of paralysis reduced his frame to a helpless wreck, but still left his restless and energetic mind to work on its way eager and unsubdued. Having attained his sixtieth year, he died at Greenock, April 11, 1839. (R. C—S.)

GALVANI, Aloïsio, or Luigi, the celebrated discoverer of galvanism, or, as he himself called it, "animal electricity," was born at Bologna in Italy in 1737. In his youth he gave evidence of a strongly devotional cast of thought, and he was accordingly educated with a view to taking orders. He changed his plans, however, and studied medicine at the university of his native town. Shortly after graduation, he obtained a public appointment as a medical lecturer, and increased his fame by publishing his *Observations on the Organs of Hearing in Birds; Observations on* *the Urinary Organs*, and by various contributions to the transactions of the university. An event, however, apparently accidental in its origin, occurred, which directed into a new channel the study of electrical science, and identified the name of Galvani with one of the most important branches of that great department of physics. His wife was preparing frogs for soup, and having skinned the animals, had placed them near the conductor of a newly charged electrical machine. Happening to touch them with a scalpel which had been in contact with the machine, she saw to her surprise the muscles of the frogs convulsed with violent spasmodic action. Galvani repeated the experiment in a variety of forms, and came to the conclusion that there existed what he called an "animal electricity" both in nerves and muscles. To this erroneous idea he clung through life, even after it had been disproved by his countryman Volta and other experimenters. He took great pains to develop his theory in regard to the phenomena in question as fully as possible, by publishing in 1791 his *Commentarius de viribus electricitatis in motu musculari*. The purport of this work, and its influence on electrical science, are fully discussed under ELECTRICITY.

In 1797 Galvani made a tour of the shores of the Mediterranean, with a view to verifying his theory by experiments on the electric eel. Soon after returning home he lost his wife; and his affliction was enhanced by his being expelled from his chair for refusing to take the oaths of allegiance when Bologna was incorporated with the Cisalpine Republic. His health and spirits gave way under these calamities, and though he was ultimately reinstated in his professorship, his death, in 1798, prevented him from profiting by his good fortune.

GALVANISM, that branch of physical science which treats of the chemical agencies of electricity, and of its influence upon the animal frame. The chemical effects of electrical action had been previously studied by Cavendish as a branch of ordinary electricity; and it was not till the year 1790, when Galvani made the interesting discovery that muscular contractions were excited in dead frogs by the contact of metals, that the new science of Galvanism was established. The boundaries of Galvanism were widely extended by the invention of the pile in 1800, by M. Volta of Corna, in consequence of which the name of Voltaic Electricity has been very generally substituted instead of Galvanism. The subject of Galvanism, including *Animal Electricity*, is treated of under VOLTAIC ELECTRICITY.

GALVANIZED IRON, iron alloyed superficially with zinc, by plunging the metal, previously well cleaned by friction with dilute acid, into a bath of melted zinc covered with sal ammoniac, and stirring it about for some time. When iron thus treated is exposed to humidity, the zinc is said to become oxidized in consequence of galvanic action. This coating protects the iron beneath from rusting; and hence galvanized iron will retain its whiteness for a long period under circumstances that would cause ordinary tinned iron to exhibit marks of corrosion.

GALVESTON, a seaport-town of the state of Texas, North America, near the eastern extremity of Galveston Island, at the entrance of Galveston Bay, Gulf of Mexico. It is the commercial emporium of Texas, and has the best and most accessible harbour on the whole coast. Its trade is chiefly coastwise with New Orleans and New York. Galveston Island is about 36 miles in length, by an average width of 2 miles. Pop. of town 4167.

GALVEZ, a town of Spain, in the province of Toledo. It stands 15 miles south-west of Toledo, has a serge manufactory, and contains 3000 inhabitants.

GALWAY, a maritime county in the province of Connaught, in the extreme west of Ireland, bounded on the north by Mayo and Roscommon, on the east by Roscommon, King's County, and Tipperary, on the south by Clare and the Bay of Galway; extending the entire breadth of the province of Connaught from the river Shannon to the Atlantic Ocean, which forms the western boundary of the county. According to the Ordnance Survey, it comprises an area of 2447 square miles, or 1,566,354 acres, of which 742,805 are arable, 708,000 uncultivated, 23,718 in plantations, 1801 in towns, and 90,030 under water. Excepting the counties of Antrim, Clare, and Fermanagh, this county comprises, in proportion to its area, a greater quantity of land under water than any other in Ireland.

Name. The name of Galway, originally applied to the town of the same name, is generally supposed to have been derived from "*Gaelis*, or *Gailes*, 'traffic or commerce,' signifying a *merchant*, and *ibh* in Irish, signifying *tribes* or *families*, whence *Gailibh, tribes of merchants*," which name was pronounced *Gallive*, and afterwards in 1440 corrupted into Galway. In the time of Ptolemy it was inhabited by the Auterii. At a later period it was divided into the districts of Clanconow, Hy-Maine, Maghullen, Lilanchia, Hy-Fiacrin-Aidne (afterwards Clanrickard), and Hy-Tartagh. In the commencement of the sixteenth century it was portioned out amongst a number of families or septs, of which the principal were the O'Flahertys and O'Maleys in the west; the Burkes and Berminghams in the north; the O'Naghtens, O'Kellys, and O'Dalys in the east; and the O'Heynes, the O'Maddens, and the O'Shaughnessys in the north. It was made shire-ground by Elizabeth in 1569, and is now divided into eighteen baronies. These are sub-divided into 120 parishes, forming the entire diocese of Kilmacduagh and portions of the dioceses of Tuam, Clonfert, Elphin, and Killaloe. The dioceses of Kilmacduagh and Clonfert are now united with Killaloe and Kilfenora under one bishop; the former archbishopric of Tuam, together with Killala and Achonry, is a bishop's see; and Elphin is united with Kilmore and Ardagh: the county is therefore under the ecclesiastical jurisdiction of the bishops of Tuam, Killaloe, and Kilmore. It is the seat of the Poor-Law Unions of Ballinasloe, Clifden, Galway, Glennamaddy, Gort, Loughrea, Mountbellew, Oughterard, Portumna, and Tuam, but small portions of the county are comprised in the neighbouring unions of Scariff and Roscommon. Galway is within the military district of Limerick, with barrack stations at Loughrea, Dunmore, Portumna, Galway, Gort, and Oughterard. The headquarters of the constabulary force, numbering about 750 men, are at Galway for the West-Riding, and Loughrea for the East-Riding.

Divisions—Eastern. The county is naturally divided by Lough Corrib into two great divisions, differing from each other in several striking points. The eastern division, which comprehends all the county except the four western baronies, rests on a limestone base, is convertible into good tillage land, and is, generally speaking, a level champaign county, but containing large quantities of wet bog; the western has a substratum of granite, and is barren, rugged, and mountainous. The southern part of the former of these divisions is supposed by some to be a continuation of the Golden Vale of Limerick, so celebrated for its fertility, and produces the finest wheat, except in the region of the Slieveboghta Mountains, which form part of the boundary between this county and Clare. The northern part of the same division is also rich pasture and tillage ground, beautifully diversified with hill and dale. Some of the intermediate country is comparatively barren; but those parts which would not repay the expense of tillage form excellent pasturage for sheep, which is the great staple commodity of the county.

Western. The western division is divided into the three districts of Connemara, Jar-Connaught, and Joyce's Country, which correspond in boundary with the three modern baronies of Ballynahinch, Moycullen, and Ross. The name of Connemara is, however, often applied to the whole district, and signifies the Bays of the Ocean. Its highest mountains are the grand and picturesque group of Binabola, or the Twelve

Pins, which occupy a space of about 25 square miles, midway between Lough Corrib and Aghris Point, the most western projection of the county. Knockenhiggen, the highest of these, is about 2400 feet high. The vale of Glen Ina is overhung by a naked perpendicular cliff 1200 feet in elevation, over which a considerable sheet of water is precipitated. But this district, although mountainous, is not an elevated country; the surface of most of it is not 100 feet above the level of the sea, rising from the edge of Galway Bay, in a gently sloping plain, to a height of not more than 300 feet, with some hills about 700 feet high. Joyce's Country, more northwards, is an elevated tract, with flat-topped hills of from 1300 to 2000 feet high, and deep narrow valleys lying between them.

Rivers.

The rivers are few, and excepting the Shannon, which forms the south-eastern boundary of the county, are of small extent. The Suck rises in Roscommon, and forms the eastern boundary, passing by Ballinasloe, and unites with the Shannon at Shannon Bridge. This latter river then forms part of the boundary of the county, passing by Shannon harbour, Banagher, Meelick, and Portumna, and presenting little that is attractive to the eye; "the banks are chiefly wide and apparently interminable plains, unenclosed—almost level with the river—bearing luxuriant crops of herbage, and feeding innumerable herds. We see scarcely any habitations; no villages or hamlets; and no road or traffic on the banks. The meadows of which I speak extend on both sides of the river for the greater part of its course from Banagher to Portumna. These meadows are all overflowed during the winter, and are let for grazing at a very high rent. For many miles there is nothing to relieve the monotony of these vast flats, excepting an old castle called Torr Castle—no otherwise remarkable than as being the only object which breaks the level. The views on this part of the Shannon brought forcibly to my recollection the banks of the Guadalquiver, between Seville and Cadiz."—*Inglis.* After leaving Portumna, the Shannon swells into the great expanse of water called Lough Derg, which skirts the county of Galway as far as the prettily situated village of Mount Shannon. The Suck is joined by the Shevin and Ahascragh rivers. The Blackwater, a trifling stream, forms part of the northern boundary between Galway and Mayo, and discharges itself into Lough Corrib. Near Shrule it sinks into the ground through an open called a shallow, and, after a short underground course, bursts forth again through several springs. The Carnamart, a small stream, passes through the southern baronies, and falls into Galway Bay. The Ballynahinch, which is considered one of the best salmon-fishing rivers in Connaught, rises in the Twelve Pins Mountains, passes through Ballynahinch Lake, and after a short but rapid course empties itself into Birterbuy Bay.

Lakes.

The lakes are numerous. Lough Corrib extends from Galway town northwards over 30,000 acres, and embraces a coast of fifty miles in extent, affording a large scope for inland navigation. It communicates with the sea by the Galway river, but as its level is 13 feet above high-tide mark, the fall is such as to prevent a water passage by the river from the bay to the lake. A former attempt made to connect them by a canal having failed, was long pointed out under the name of Lynch's Folly; but the whole extent of Loughs Corrib and Mask are now being made navigable to the sea at Galway. The lake is studded with many islands, some of them thickly inhabited. Near it is Lake Ross, which, with some smaller lakes, receives a large supply of water from streams, but has no visible outlet. In Connemara are a number of lakes extending nearly 20 miles from Lough Corrib to the sea, besides several others in other parts. About 25 of these are more than a mile in length each, and there are upwards of 100 of smaller dimensions extending almost the whole length of Connemara. "It was impossible to cast the eye over the vast inclined plains of bog-land, skirted by fine water levels, which seemed to invite draining, without feeling a conviction of the immense capabilities of this part of Ireland; and seeing, in prospective, these vast tracts bearing abundant produce—and the chains of lochs carrying that produce—on the one side to Lough Corrib and Galway Bay, and on the other to Birterbuy Bay, or one of the other bays which lie to the westward."—*Inglis.* Lough Rea, at the town of the same name, is more remarkable for scenic beauty than extent. Besides these perennial lakes, there are several low tracts which are covered with water during a great part of the year: they are called Turloughs. The largest is Turloughmore, extending from Tuam nearly to Clare Galway. Another of large size is near Rahasane. A few sheep are grazed on them during four months in summer, but they are unprofitable in winter. They are, however, mostly of easy drainage, and some of them have already been drained, whilst others are now undergoing the process.

Coast.

Galway enjoys the advantage of a very extended line of sea-coast, indented by numerous and safe harbours, rarely used except by a few coasting and fishing vessels. Commencing at the coast of Mayo in the north are the Killeries, two bays which separate the counties of Galway and Mayo. The first bay on the western coast capable of accommodating large ships is Ballynakill, sheltered by Truchelaun or Heath Island. Next in succession is Cleggan Bay, having Ennisbofin in its offing. Streamstown is a narrow inlet, within which are the inhabited islands of Tarbert and Innisturk. Ardbear harbour divides itself into two inlets, the northern of which is terminated by the town of Clifden, with excellent anchorage opposite the castle; the southern inlet has also good anchorage within the bar, and has a good salmon-fishery. Mannin Bay, though large, is much exposed, and but little frequented by shipping. From Slyne Head the coast turns eastward to Roundstone Bay, having its entrance protected by the islands of Innisnee and Innislacken; here the whole British navy could lie in safety. Next in order is Birterbuy Bay, studded with islands, islets, and rocks, but deep and safe. Between it and Kilkerrin Bay are the islands of Mason, Mynish, and Fynish, all inhabited; Elanmaedara, and Cruanakeely which was used as a deer park by Mr Martin of Ballynahinch. Kilkerrin Bay, the largest on this coast, has a most productive kelp shore of nearly 100 miles, including its islands of Annaghvane, Garomna, Lettermore, Lettermullen, Knappagh, and Furnish, yet its mouth is but eight miles broad. Between Garonna and the main-land is Greatman's Bay, and close to it Costello Bay, the most eastern of those in Connemara. Next is the bay and harbour of Galway. At the Oranmore the coast turns southwards, and presents the harbours of Rynville, Ardfry, Ballynacourty, Stradbally, Killeen or New Arran, Kinvarra, and Duras, where the county joins that of Clare. The whole of this coast, from Greatman's Bay eastward, together with the northern shore of Clare, to Blackhead, is comprehended in the Bay of Galway, the entrance of which is protected by the three limestone islands of Arran, Innishere, Ennismain, and Arranmore, forming a distinct barony, and remarkable as well for many relics of ancient pagan and monastic institutions, as for the singular mode of life of the inhabitants, who are partly agriculturists and partly fishermen, wholly uncivilized, very ignorant and superstitious, and are occasionally reduced to great distress.

Climate.

The climate, though most variable, and exposed to frequent and violent gales from the west, is mild and salubrious. The country is subject to no diseases except those incident to a population not attentive to domestic neatness, and frequently in a state of great destitution. Frost or snow seldom remains long on the western coast, and cattle of every description continue unhoused during the winter.

Geology.

The boundary line between the limestone and granitic district is easily discernible by the diminution of the verdant hue which marks the latter. The high road from Galway to Oughterard nearly marks the division. All the country to the north and east of this limit is limestone, all to the south and west granite, excepting some detached masses of primitive limestone between Oughterard and Clifden, and some scattered portions of other minerals, of great variety of appearance. The component rock of Binabola is quartz, in general distinctly stratified, or at least schistose. The position of its beds is various. Towards the western shore they are vertical, easily splitting by intervening mica plates, and affording good building stone. Limestone occurs in some places along the foot of these mountains, where also is some green serpentine, which is conveyed to Galway and elsewhere for ornamental purposes. Round the basis of this group are also gneiss and mica slate, with bands of hornblende and primitive mica. Along the north side of Lough Corrib to Ballynakill the mica slate and hornblende rise into mountains, and the limestone disappears. From Lough Mask to the Killeries is a transition country of greenstone and grauwacke slate, covered by the old red sandstone or glomerate. The hill of Glan on the shore of Lough Corrib exhibits, in a small compass, all the formations which occur in the district. The western end is quartz; the north-eastern side mica slate; the middle is penetrated by beds of mica slate, containing hornblende and granular mica covered by thick beds of pyritous greenstone. On the south and east are granite and syenite, which runs under the sandstone, conglomerate towards Oughterard, and this again passes under the flœtz limestone, which, passing Lough Corrib, occupies the greater part of Connaught and Leinster. Along the borders of the flœtz limestone is a series of vast caverns, usually traversed by subterraneous rivers, a phenomenon which, though not of unfrequent occurrence in limestone countries, is peculiarly striking here. The succession of the stratified rocks may be distinctly seen at the water-fall at Oughterard. A fine gritstone, highly valued for making mill-stones, is raised near Dunmore. Crystalline sand, of a superior quality for scythe boards, occurs at Lough Coutra. Lead, zinc, copper, sulphur, ore, mundic, and bismuth, have been discovered in various parts of the western division of the county. Iron was raised at Woodford, and smelted until the timber was exhausted. The mountains of Slieveboghta, which separate Galway from Clare, are siliceous. A beautiful black marble, without spots or flaws, and susceptible of a high polish, is raised near the town of Galway in large quantities, particularly for chimney-pieces. **Mineral springs.** Mineral spas, mostly chalybeate, are abundant. That at Kingston was pronounced by Kirwan to be one of the best in Europe. At the village of Quose is a well which instantly kills poultry that drink of it. A spa at Oughterard draws many invalids to that town. Others at Athenry, Woodbrook, Rathglass, Killimore, and Abbert, are prized in their respective neighbourhoods.

People. The inhabitants of Galway are not distinguished by any striking peculiarities from those of the rest of the province. On the settlement of Ireland after the Restoration, such of the native Irish as had been allowed to possess property were removed from other provinces and compelled to exchange their properties for lands in Connaught supposed to be of equal value with those they were forced to surrender. They were also prohibited from settling in any of the corporate towns, or within a mile of the sea-coast, the boundary of which was called the mile-line. Thus cooped up, and debarred all opportunities of intermixing with strangers, it is not surprising that they have retained many peculiarities of appearance and manners. These peculiarities, however, are not confined to this county.

Population. The population of the county has been stated as follows by the under-cited authorities :—

1760—De Burgo	82,188
1792—Beaufort	142,000
1812—Parliamentary return	261,000
1821—Do	337,374
1831—Do	414,684

In 1841 the population was 440,198, the excess in the number of females being 1070, whilst in 1851 the total population was only 321,230, and the number of females preponderated by 7270.

Representation in parliament. Notwithstanding its great extent and proportionate population, the county sent but eight members to the Irish parliament; two for the county at large, and two each for the boroughs of Galway, Athenry, and Tuam. By the Act of Union the number of borough members was reduced to three, two for the county and one for the town of Galway. By the Reform Act this number was increased to four; the county and town now returning two members each. The constituency previously to the disfranchisement of the forty-shilling freeholders was the most numerous of any county in Ireland. The changes produced on its numbers by the Catholic Relief Act, and by the Reform Act, &c., will best appear by the following table :—

	L.50.	L.20.	L.10.	40s.	Total.
1829	828	274	950	32,055	34,107
1830	897	299	1812	...	3,008
1831	326	191	2540	...	3,057
1853	...	...	...	...	3,344

Education. From the population returns of 1821, and those of the commissioners of education in 1824–26, the state of education was as follows :—

	Boys.	Girls.	Sex not ascertained.	Total.
1821	7,690	3161	...	10,851
1824–26	11,874	6487	463	18,824

Of the number of pupils stated in the latter return, 1471 were of the Established church, and 17,090 Roman Catholics. The number of children attending public schools in 1841 was, in rudimental schools 9046 males, and 5691 females; in superior schools 424 males, and 170 females—total 15,331. In 1853 there were 174 national schools in operation, attended by 21,572 children; 10,537 males, and 11,035 females. The proportion of Protestants to Catholics, estimated from the relative numbers of the children of each persuasion receiving scholastic instruction in 1824, was as 1 to 11½ nearly.

Productions and cultivation. The eastern part of the county produces the best wheat, the growth of which requires the preparatory culture of potatoes. Oats are frequently sown after potatoes in moory soils less adapted for wheat. Manure is generally abundant, but most so in the western districts, which do not admit the growth of wheat. The flat shores of the bays there are formed of coralline sand, and the sea-weed thrown up after storms affords a copious supply of vegetable manure. Limestone, gravel, and marl is to be had in most other parts. When a sufficient quantity of manure for potatoes cannot be had, the usual practice is to pare and burn the surface. Potatoes are still planted in ridges by the small farmers, who make much use of spade culture, particularly in the upland districts, where the ruggedness of the surface is unfavourable to the application of the plough. In many places on the sea-shore fine early potatoes are raised in deep sea-sand, manured with sea-weed, and the crop is succeeded by barley. **Fences.** The fences most in use are formed of the stones collected from the surface, and raised to the height of five or six feet in dry walls, broad at the base, and narrowing upwards. According to the returns of the census commissioners of the year 1841, the county of Galway was then divided into 44,393 farms of various dimensions, viz. 28,006 of from 1 to 5 acres, 12,677 from 5 to 15 acres, 2032 from 15 to 30 acres, and 1678 of greater extent. The estimated total value of the aggregate live stock at the same period upon the whole of these farms was L.1,050,431.

Farms.

The number of holdings of each description in the county of Galway in the years 1852 and 1853 was—

	Not exceeding 1 acre.	From 1 to 5 acres.	From 5 to 15 acres.	From 15 to 30 acres.	From 30 to 50 acres.	From 50 to 100 acres.	From 100 to 200 acres.	From 200 to 500 acres.	Above 500 acres.
1852	2·373	6·010	11·996	7·191	3·051	2·059	1·126	796	185
1853	2·335	5·713	11·931	7·551	3·128	2·138	1·239	812	250
Difference in 1853,	−38	−297	−65	+360	+77	+79	+113	+16	+75

From this return it appears that 400 small holdings were absorbed in the larger description of farms, which increased in one year 720 in number. This increase, however, could not have arisen entirely out of the consolidation of 400 farms of small extent, but must have been mainly caused by the addition of tracts of mountain-land hitherto returned as "untenanted bog and waste," and shows an increase in the extent of cultivated land, which amounted in 1852 to 229·421 acres, and in 1853 to 235·257 acres, being an increase of 5836 acres brought into cultivation. The extent of each class of crops cultivated was—

	Corn, Beans, and Peas.	Potatoes.	Turnips, Mangel-Wurzel, Beet-root, Carrots, and Parsnips.	Cabbage, Vetches, and other green crops.	Flax.	Meadow, Clover, and Rape.
1852	112·684	41·366	17·450	1·966	546	55·409
1853	113·397	46·134	19·502	2·023	784	53·417
Difference in 1853,	+·713	+4·768	+2·052	+57	+238	−1·992

Cereals.

The cultivation of wheat, which in 1847 occupied 33·523 acres, had declined in 1853 to 13·731 acres; the cultivation of barley has also decreased, but a considerable increase has taken place in the amount of other crops cultivated, especially potatoes, beans, peas, and green crops. The total produce of potato, cereal, and other crops, with the proportion which they bore to the population in 1853, was as follows:—

	Corn, Beans, and Peas.	Average per head.	Potatoes.	Average per head.
	Tons.	Lbs.	Barrels.	Stones.
Galway............	86,895	605	2,449,432	152
All Ireland........	2,046,794	700	45,932,301	146

Live stock.

The quantity of live stock in the county has rapidly increased of late years, as will appear by the following return for the five years from 1849 to 1853.

Years.	Horses.	Mules and Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.	Total Value.
	No.	No.	No.	No.	No.	No.	No.	L.
1849	22,258	10,410	96,707	244,912	22,723	8,655	246,088	1,134,536
1850	22,220	11,237	105,803	287,324	26,373	9,419	276,528	1,246,258

Markets.

The chief markets for grain are Galway, Loughrea, Tuam, Ballinasloe, Gort, Eyrecourt, and Mount Bellew. The great cattle fair of Ballinasloe is held annually in October, and large numbers of sheep and horned cattle are offered for sale; the prices obtained here exercising an extensive influence upon those in other markets throughout the kingdom. Flour-mills are numerous. Those parts of the eastern district less fitted for grain are employed in pasturage. Heathy sheep-walks occupy a very large tract between Monivea and Galway. An extensive range from Athenry, stretching to Galway Bay at Kinvarra, is also chiefly occupied by sheep.

Pastures.

Manufactures.

Manufactures are not carried beyond the demand caused by the domestic consumption of the people. Coarse friezes, flannels, and blankets are made in all parts, and sold largely in Galway and Loughrea. Connemara has been long celebrated for its woollen stockings. They are knit by the hand, and have a softness and elasticity, caused by the fineness of the wool used, superior to that of the woven article; but they are slight, and therefore stand but little wear. Coarse linen, of a narrow breadth, called bandle linen, is also made for home consumption. The manufacture of finer linens and diapers has been attempted, but with little success. The manufacture of kelp, introduced about the year 1700, was formerly one of the great sources of profit on the western shores, and is still to some extent carried on. Of the minor manufactures, marble is wrought for domestic and sepulchral purposes in Galway. Felt hats and coarse straw bonnets are made in several places. Feathers are brought in great quantities from the islands of Arran, where they are procured from the puffins and other sea-fowl that frequent the cliffs on the coasts. They are caught by men trained to the practice, who are let down at night from the projecting crags above, by means of a rope tied round their waist, to the haunts of the birds; and after supplying themselves with all they can capture, they are hauled up again in the morning. Sea fowls' eggs are collected in large quantities in the same manner.

Feather collectors and wild fowl.

Antiquities.

Amongst the relics of antiquity are the round towers of Ardrahan, Ballygaddy, Kilbannon, Kilmacduagh, Meelick, and Murrough. The last-named of these is of very small dimensions: that of Kilmacduagh, which is still fifty feet high, inclines seventeen feet from the perpendicular. Raths are numerous, and several cromlechs are still to be seen in good preservation. The ruins of monastic buildings are also numerous. That of Knockmoy, about six miles from Tuam, said to have been founded in 1180 by Cathal O'Connor, was adorned with rude fresco paintings, which are still discernible, and were considered valuable by antiquaries as being the best authentic representations existing of ancient Irish costumes. Ancient castles and square towers of the Anglo-Norman settlers are very numerous; some have been kept in repair, and are still inhabited; the greater number are in ruins. The castle of Tuam, built in 1161 by Roderic O'Connor, king of Ireland at the period of the English invasion, is said to have been the first building of this description of stone and mortar in Ireland. The remains of a round castle, a form of building very uncommon in the military architecture of the country, is to be seen between York and Kilmacduagh. (H. S—R.)

Galway town.

GALWAY, the county town, formerly designated the Liberties of Galway, and a county in itself, having an exclusive local jurisdiction, extending two miles on every side except the south. It stands on the northern shore of the Bay of Galway, on the eastern bank of the river of the same name, and is inclosed on the land side by the baronies of Clare, Dunkellin, and Moycullen. It is supposed by some to be the Nagnata of Ptolemy. It certainly was considered a position of much importance from the earliest period, as in the divisions of the island into north and south, at first made by the descendants of Heremen, and afterwards repeated by Conn and Eogan, it was fixed upon as the eastern extremity of the line of demarcation, which proceeded eastwards to Dublin. Little, however, is known of it until after the arrival of the English, at which time it was under the protection of O'Flaherty, who possessed the adjoining district to the west. On the extinction of the native dynasty of the O'Connors, the town fell into the hands of the De Burgos, the head of a branch of which, under the name of M'William Eighter, long governed it by magistrates of his own appointment. After it had been secured by walls, which began to be built in 1270, it became the residence of a number of enterprising settlers, through whom it attained a position of much commercial celebrity. Of these settlers the principal families, fourteen in number, are still known by the name of the Tribes of Galway. Their names are preserved in the following distich:—

Athy, Blake, Bodkin, Browne, Deane, Darcy, Lynch,
Joyes, Kirwan, Martin, Morris, Skerrett, French.

The tribe, whose name is not included in the rhyme, was called Ffont. With the exception of Athy and Kirwan, all these families were of Norman, Saxon, or Welsh descent. They became so closely connected by intermarriages, that dispensations were frequently requisite for the canonical legality of marriages among them. Sir Olivier St John, describing Connaught in 1641, says, that "the merchants (of Galway) are rich, and great adventurers at the sea; their commonaltie is composed of the descendants of the ancient English families of the towne, and rarelie admit any new English among them, and never any of the Irish." The town rapidly increased from this period in wealth and commercial rank, in this respect far surpassing the rival city of Limerick. Richard II. granted it a charter of incorporation with liberal privileges, which was confirmed by his successor. It had the right of coinage by act of parliament; but there is no evidence to show that it exercised the privilege. Another charter, granted in 1545, extended the jurisdiction of the port to the islands of Arran, permitted the exportation of all kinds of goods except linens and woollens, and confirmed all the former privileges. Large numbers of Cromwell's soldiers are said to have settled here; and there are many traces of Spanish blood among the population. The commercial prosperity of the town, which had been steadily advancing under the protecting favour of the government, received its first check by an unfavourable decision of the Court of Chancery respecting the prisage of wine; a toll paid by every sea-port to the head of the Ormond family, in right of his office of chief butler to the king, and from the payment of which Galway claimed exemption. Wine was the great staple of commerce. The payment of prisage, which consisted of two pipes of wine from every vessel discharging at the port, was a heavy drawback upon its profits. But soon after, its municipal privileges were extended by a charter from James I., whereby the town, and a district of two miles round in every direction, were formed into a distinct county, with exclusive jurisdiction and a right of choosing its own magistrates. During the civil wars of 1641, the town took part with the Irish, and was surrendered on articles to the parliamentary forces under Sir Charles Coote; after which the ancient inhabitants were mostly driven out, and their property was given to adventurers and soldiers, chiefly from England. On the accession of James II. the old inhabitants entertained sanguine hopes of recovering their former rights. But the successes of King William soon put an end to their expectations; and the town, after undergoing another siege, again capitulated to the force brought against it by General de Ginkle, on condition of a safe conduct for the garrison to Limerick, pardons and the protection of property and civil rights to the townsmen, and the free exercise of their religion in private. The penal statutes passed by Queen Anne against the Roman Catholics rendered the latter clause of the capitulation nugatory, and exposed that portion of the population which stood in need of protection to much persecution, particularly on the breaking out of the rebellions of 1715 and 1745 in Scotland. In the beginning of the present century the walls were thrown down, and buildings erected on their site. Several streets have also been carried out eastwards, to which the name of the New Town is given.

Galway is governed by the high sheriff, recorder, local magistrates, and a board of twenty-four commissioners, elected triennially, who have charge of the property of the town arising from tolls, amounting to about L.2000 per annum, besides harbour dues, which are chiefly applied to the repair of the pier, dock-gates, &c. The right of returning members was exercised at an early period. By the Act of Union the number of its representatives was reduced to one; but the second member was restored by the Reform Act. The population in 1821 amounted to 27,775, and in 1831 it had increased to 33,120; in 1841 it had diminished to 17,275, and in 1851 risen to 23,695.

Ecclesiastical arrangements.

In its ecclesiastical arrangements the town formed part of the ancient diocese of Enachdune or Annaghdown, which was incorporated in 1324 with the archdiocese of Tuam. But in 1458 it was erected into an exempt jurisdiction by the name of the wardenship of Galway, to be governed by a warden and eight vicars, chosen by the inhabitants under the authority of the bull of Pope Innocent. In 1486 one of the chief merchants of the town built part of the college-house for the wardens and vicars; and soon afterwards the parishes of Furanmore, Moycullen, Skreen, and Ballenclare were united to the wardenship by William Joyes, a native of the town and archbishop of Tuam. At the Reformation it was deprived of much of its property; and since that time there have been two wardens, one nominated by the Protestant members of the corporation, and a Catholic, chosen by the ancient inhabitants or tribes.

Situation.

The town, which is old-fashioned and crowded, without any good streets, and with very few good houses, is situated on the extremity of a projecting neck of land, rising with a gentle acclivity on both sides of the river Corrib, which connects Lough Corrib with the sea. The space within the walls formed an oval of about 3426 square perches. Some of the streets are very narrow, and contain some curious specimens of old buildings, chiefly in the antique Spanish fashion, being square, with a court in the centre, and a gateway opening into the street. St Nicholas' Church is the most remarkable building in the town. It is cruciform, 152 feet long by 126 broad, with a steeple rising over the nave, and the side aisles separated from the centre by Gothic pillars. There are several antique monuments in it. The exchange, or tholsel, near the church, consists of an open corridor, 90 feet long by 28 broad, with a front of arches supporting an upper story, in which are apartments for holding their own courts, and for other public purposes. The county court-house is an elegant building, with ample accommodation for all the purposes of its erection; and near it are the county and town prisons. The town also contains the county infirmary, the union workhouse, and also a fever hospital. A grammar-school, maintained by the governors of Erasmus Smith's bequest, is in the immediate neighbourhood of the town. The new Queen's College, built of beautiful gray limestone, is an elegant and extensive quadrangular structure in the Tudor Gothic style. Near the college is a new national (model) school. Immense works have long been in progress to connect the navigation of the Bay of Galway with that of the great lakes Corrib and Mask. Extensive new docks have been constructed.

Trade a
commerc

Though much reduced in the scale of mercantile importance, it is still an extensive exporting town; the chief articles exported being agricultural produce, wool, and marble. Galway is divided into the old and new towns, and the maritime suburb of Claddagh, inhabited almost entirely by fishermen and their families, who have acquired or retained peculiar usages and habits of their own. They marry among one another, and jealously resist the residence of strangers. They were formerly governed by a mayor, elected by themselves, whose only mark of office was the white sail of his boat, and a flag at its mast-head; but to him they paid implicit deference. He regulated the time of the sailing of the fishing fleet, and its movements when at sea. This usage has been discontinued, but the Claddaghites are still governed by their own laws in matters relating to fishing.

At home the women are mistresses; the moment the boats' cargoes are unloaded, the whole is transferred to them; they make the sales and spend the produce, their husbands being fully satisfied with the liberal allowance of spirits and tobacco they receive from them: but on their fishing expeditions no ardent spirits are suffered in their boats; their stock then consists solely of potatoes, oaten bread, and water. Their language is Irish, which they speak with a harsh discordant accent. The dress of the men consists of three flannel vests under a fourth of white dimity, a blue rug jacket, and blue plush breeches, blue worsted stockings, a horizontal-brimmed hat, and a red silk neckerchief. Among the women, the matron's dress is a blue mantle, a red body-gown and petticoat, and a silk handkerchief on the head. Unmarried women are known by their muslin caps trimmed with lace. The females of all ages are remarkable for attention to neatness, both in their persons and household. Their religion is almost exclusively Roman Catholic, with but one or two exceptions. The rigid exclusiveness which has hitherto retarded the civilization of this community will in all probability be broken down by the application of improved methods of fishing, together with the introduction of capital consequent upon the opening of the markets by the Midland Great Western Railway, and the operation of the Limited Liabilities Act.

The towns of chief importance after the county town are Tuam, with a population in 1851 of 4938; Loughrea, pop. 6342, situated on the borders of the lake of the same name; Gort, pop. 2405; Ballinasloe, pop. 4063; and the new and beautifully situated town of Clifden. (H. S—R.)

GAMA, Vasco da, the first European who reached India by doubling the Cape of Good Hope, was born at Sines, a small sea-port of Portugal. Of his early history so little has been recorded, that even the date of his birth is unknown. On attaining manhood, he found that the success of Columbus had given a powerful impulse to the spirit of maritime adventure. In 1487 Pedro Da Covilham had set out for India by way of Egypt and the Red Sea, accompanied by Alfonso de Payva. At Cairo the latter of these travellers separated from his companions, and went in quest of "Prester John," a Christian king who was reported to be then reigning in Abyssinia over a people in a high state of civilization. Covilham, prosecuting his voyage alone, reached Goa and Calicut, and satisfied himself of the importance of the whole country as a field of commercial enterprise. He also became convinced of the possibility of reaching India by the Cape of Good Hope, a route which he found to be quite familiar to the Indian and Arabian traders. In the same year in which Covilham had set out on his eastern voyage, Bartholomew Diaz had returned to Lisbon, after discovering that the southern coast of Africa was really bounded by a navigable sea. On the 4th July 1497, Vasco da Gama sailed from Lisbon with a small squadron of three vessels manned by sixty sailors, bent on making his way to India round the Cape of Good Hope, then known as the Cabo Tormentoso, or Stormy Cape. The hardships and dangers to be encountered were appalling, and led to a mutiny, which was with difficulty quelled by the firmness and prudence of the commander. He doubled the Cape at length, and reached in safety the small town of Melinda, where he secured the services of an Indian pilot. In twenty-three days they reached Malabar, and on the 20th May 1498 they came to anchor at Calicut. Gama was well received by the zamarin; whom, though not without difficulty, he convinced of the advantages that would accrue to his country by the establishment of a commercial treaty with Portugal. Gama then turned his prows homeward; and, having touched at various points on the Asiatic and African coasts, he once more cast anchor in the Tagus in the September of 1499, after an absence of two years and two months. Emmanuel received him with great honours, ennobled him, and gave him the title of admiral of the Indian, Persian, and Arabian seas. The effect of Gama's voyage was soon visible in the ruined trade of the Italian commercial republics, which had hitherto monopolized the traffic of the east. In prosecution of Gama's discoveries, another fleet was sent out to India, under Cabral, who accidentally discovered the Brazils, and on reaching his destination established a factory at Calicut. The natives, instigated by the Moorish merchants, who were jealous of the Portuguese, rose up in arms, and murdered all whom Cabral had left behind. To avenge this cruelty, the Portuguese fitted out a powerful armament, of which the command was given to Gama. The admiral set sail, and devastated those parts of Africa and India where he had formerly been received in a hostile spirit. He executed especial vengeance upon Calicut, which he bombarded and reduced to ashes, at the same time hanging the sailors of the vessels in the harbour which had fallen into his hands. He then sailed away to Cochin, where he established a factory, from which the power of Portugal radiated over India. In 1503 he returned home, and as before was welcomed with honours and titles, but was not immediately re-appointed to the command in India. He remained at home in inaction during nearly twenty years; but in 1524 (some years after the death of the great Albuquerque, who had been consolidating the Portuguese power in the east), Gama was appointed viceroy of Portuguese India. Not long after arriving at Cochin Gama died, in 1525, and was buried there; but thirteen years later his bones were disinterred and conveyed to Portugal by order of John III., king of that country.

Vasco da Gama was a man of great ability, courage, and enterprise; but he possessed none of these qualities in a higher degree than many others of his contemporaries who have long since passed into oblivion. He owes no small portion of his fame to the fact of his being the hero of a part of the national epic of Portugal. The moment of his doubling the Cape of Good Hope, and seeing in the clouds the Spirit of that stormy region, has been often seized by painters as a striking subject for pictorial delineation. One of the most remarkable of these pictures is that by the late David Scott, of Edinburgh.

GAMALIEL (*i.e. God is my rewarder*), a member of the Sanhedrim in the early times of Christianity, who, by his favourable interference, saved the apostles from an ignominious death (Acts v. 34). He was the teacher of the apostle Paul before the conversion of the latter (Acts xxii. 3). He bears in the *Talmud* the surname of *Hazoken*, "the old man," and is represented as the son of Rabbi Simeon, and grandson of the famous Hillel. He is said to have occupied a seat, if not the presidency, in the Sanhedrim during the reigns of Tiberius, Caligula, and Claudius, and to have died eighteen years after the destruction of Jerusalem. There are idle traditions about his having been converted to Christianity by Peter and John (Phot. *Cod.* clxxi., p. 199); but they are altogether irreconcilable with the esteem and respect in which he was held even in later times by the Jewish Rabbin, by whom his opinions are frequently quoted as an all-silencing authority on points of religious law.

GAMBEER. See Catechu.

GAMBIA, an important river of Western Africa, flowing westward through Senegambia, and falling into the ocean at Bathurst, in N. Lat. 13. 30., W. Long. 16. 40. Its sources have never been explored by Europeans, but it has been ascertained to take its rise among the lofty range of mountains which form the eastern front of Foota falls, and is estimated to have a course of upwards of 1000 miles. It is about 9 miles in width at its mouth, between Cape St Mary on the S. and the Bird's Island on the N. It is navigable for vessels of 300 tons for 60 leagues, and for smaller vessels to the falls of Barraconda 250 leagues from its mouth. In the beginning of 1851 Governor Macdonnell proceeded with a party, in open boats accompanied by a canoe, 160 miles above Barraconda. He says, "We passed a long way beyond the Nyarico, a river which flows into the Gambia from the northward, and is mentioned by me in a former report. Near it I was waited on by the inhabitants of a town called Jallacoota, who expressed a strong desire that some of our traders would penetrate to their country, as they had more corn and ground nuts than they could use, but had no means of bartering them for goods which they wanted. We did not find near the banks of the river any, or at least but few, signs of cultivation or inhabitants. Nevertheless, apart from the possibility of extending our commerce, the mere geographical question of the direction and extent of the course of the Gambia is one replete with interest, and which I hope may ere long be set at rest. It does not appear that much expense or danger would attend such an expedition if undertaken at the proper season, viz., the end of December or beginning of January. I and my party bivouacked fifteen nights in the woods after leaving the 'Dover,' and returned in perfect health. The abundance of game to be found in the country would ensure provisions, the carriage of which is in all such undertakings a great difficulty."

The British colony of Gambia consists of several trading stations on this river, and in 1851 contained 5693 inhabitants, as follow:—

	Whites.		Coloured.	
	Males.	Females.	Males.	Females.
Island of St Mary.......	167	13	2192	1890
M'Carthy's Island.......	8	0	637	526
Barra Point..............	1	0	131	74
Cape St Mary............	1	1	36	16
Total,	177	14	2996	2506

St Mary's Island lies at the mouth of the river, on the S. side, close to the continent, and is about 15 miles in length from N. to S., but of very inconsiderable breadth. The surface is a slightly elevated plain. The soil is sandy, with a small admixture of loam. Bathurst Town stands on the E. side of the island, about 12 or 14 feet above high-water mark, and is nearly surrounded on three sides by a tolerably deep and rapid river. A public hospital, church, courthouse, and public offices, are in course of construction, or have lately been finished.

M'Carthy's Island is generally said to be about 250 or 300 miles above St Mary's, and according to the Admiralty charts it is 235 miles above Bathurst, but Dr Madden says it is not more than 175 miles above it. It is about 5½ miles in length, by 1 in breadth. Like St Mary's, it is but little raised above the river, and both are in a great measure covered with water during the rainy season.

In 1852 the total value of the exports from this colony was L.217,856; of imports, L.110,174. The chief exports are ground nuts, wax, hides, ivory, timber, gold dust, palm-oil, gum-arabic, and bees'-wax.

GAMBLING or GAMING. The most important games are considered under their several heads, and therefore do not require particular notice in this place. It is here intended to treat of the department of jurisprudence and legislation, which deals with gambling as a vice. None of the practices which merge from harmless enjoyment to vice has perhaps afforded so difficult a problem to the moralist and legislator. The danger of encountering the gambling propensity with inflexible penal prohibitions has been too amply exemplified, and at the present day gambling is perhaps nowhere so rife and dangerous as in those parts of the United States where the laws for its suppression are the most peremptory and severe. Legislation encounters the double danger of suppressing harmless and genial amusements because they are offensive to morbidly austere minds, and of aggravating vicious propensities by violent suppression instead of judicious discouragement. That much evil has been done by ill-devised laws against gambling is too clear, but at the same time the most zealous advocate of civil freedom and non-intervention will hardly venture to say that penal laws against so desolating and so infectious a propensity as gambling are not necessary.

In Rome gambling was a conspicuous vice under the empire, but the civil law contains only a limited amount of legislation on this subject. Of the tenor of the few vestiges in the corpus juris, a succinct account is found in the Report of the Select Committee on Gaming, in 1844, where it is said that "All games of chance, with the exception of certain manly sports, five in number, were absolutely prohibited; and the lawful amount of the stakes were in all cases restricted to a certain sum. The loser could never be sued in case of non-payment; and an action was given for monies lost, during the space of fifty years to himself and his heirs, or, in their default, to any person who chose to prosecute. The municipal body in the town where the loss took place was specially enjoined to do so, and was to spend recovered money towards public purposes."—(P. 199.)

We have here the valuable principle of refusing legal remedy for obligations tainted with a gambling character, which has generally been tacitly adopted throughout the other countries of Europe, but was reluctantly, and as it were by force, dragged into the English law. One of the pervading technicalities of the English common law, which makes a "consideration" the most essential element of a sufficient contract, made it be "agreed that a person who wins money at gaming may establish a special *indebitatus assumpsit* for it; for the contract is not unlawful in itself, and the winner's venturing his money is a sufficient consideration to entitle him to the action."—(Bacon. Abridg.) In Scotland the position taken from the beginning, as founded on the civil law, was, that the courts of law were created to do substantial justice in the serious business of life between man and man, and were not to be occupied with the enforcement of the fanciful and capricious, if not vicious, obligations of the gaming table and the betting stand. In England, by a laborious application of specialties, the protection of the law was by slow degrees removed from this class of obligations. Wagers, however, continued to be very troublesome, and somewhat scandalous to the courts of law; and in 1844 Mr Starkie, Q.C., stated to the committee of inquiry on gaming that "The general rule of the common law is that a wager is a valid contract; but there are many exceptions to it, founded upon the principle that the wagers so excepted are against sound policy and convenience." And he says further, "In modern times the courts have gone farther than formerly in making exceptions on grounds of policy; and it is probable that several cases of wagers which formerly were held to be valid, as within the general rule, would now be deemed to fall within the principle of exception." The committee recommended the adoption in England of the broad principle followed in Scotland; and accordingly the gambling act of 1845 provided that "all contracts or agreements, whether by parole or in writing, by way of gaming or wagering, shall be null and void; and that no suit shall be brought or maintained in any court of law or equity for recovering any sum of money or valuable thing alleged to be won upon any wager, or which shall have been deposited in the hands of any person to abide the event on which any wager shall have been made." (§ 17.)

From the reign of Henry VIII. downwards, several statutes were passed for the forcible suppression of gaming in England. The earlier acts in general applied only to artificers and humble people, but subsequently legislation was professedly levelled against all classes alike. It would be difficult to say whether the rich or the poor most effectually baffled and evaded these enactments. One incident in 1844 showed how little they were respected. By the statute of the 9th of Queen Anne, when any person gained in a wager a sum exceeding L.10, the loser was entitled to pursue for repetition of the stake if he had paid it; and if he failed to take advantage of his privilege of restoration within three months, any stranger might pursue for treble the amount with costs. The provision had been forgotten, until in 1844 a body of professional informers resolved to act on it. They raised a crowd of actions against many affluent men eminent on the turf; and the alarm was so sensibly felt in parliament that an act was instantly carried through to stay the proceedings. It was fortunate that the legislature were then occupied with the whole question of the gambling laws in England, and in the following year they passed the act already alluded to (8th and 9th Vict., cap. 109), intended to furnish a complete code of the penal laws against gambling. On the narrative that "doubts have arisen whether certain houses alleged or reputed to be open for the use of the subscribers only, or not open to all persons desirous of using the same, are to be deemed common gaming houses," a definition is in this act afforded of the establishment which the law is to count a gaming house, and it is sufficient "that such house or place is kept or used for playing therein at any unlawful game, and that a bank is kept there by one or more of the players exclusively of the others, or that the chances of any gain played therein are not alike favourable to all the players, including among the players the banker or other person by whom the game is managed, or against whom the other players stake, play, or bet."

For some years the peculiarly English practice of betting on horse-races had been rising to a climax, until, on the occasion of each of the great periodical races, it became a popular frenzy in which some classes of the community lost all sense of discretion and integrity. The metropolis was filled with ephemeral establishments called betting-houses, and the daily papers swarmed with the advertisements of their keepers, who professed to have private and authentic information to impart about the horses known by adepts to be certainly successful. In addition to their dissemination of a taste for gambling among the poor and the young, there was the minor evil that when the settling time came the establishment was often found to be closed, the owner appropriating all deposits. In 1853 an act was passed (16th and 17th Vict., cap. 119) "for the suppression of betting-houses," by which every such establishment was subjected to the gambling act already referred to, and rendered liable to be dealt with as "a common nuisance, and contrary to law." The act just cited does not extend to Scotland. The old statute law of that part of the empire is directed to the extermination of the practice of gambling; but, according to a principle different from anything known in England, the provisions are modified or neutralized by disuse. The act of 1621, cap. 14, provides that any sum above 100 merks gained within 24 hours at gaming, or gained in horse-racing, shall go to the poor of the parish, but practical difficulties have interfered with the recovery of the sums thus nominally forfeited. (J. H. B.)

GAMBOGE, a concrete vegetable juice or gum-resin obtained by making incisions in the bark of the *Garcinia cambogia*, a forest tree of the same genus as that which affords the mangostein, the most exquisite fruit of the east. It is imported sometimes in orbicular masses, but generally in cylindrical rolls; is of a bright yellow colour, opaque, brittle, has a vitreous fracture, no smell, and a slightly acrid taste. It forms a beautiful yellow pigment, which is much employed by painters in watercolour; is used to stain wood in imitation of box; and the tincture enters into the composition of the gold-coloured varnish for lacquering brass. It also gives a beautiful and durable stain to marble. Medicinally it is a drastic purgative.

GAME LAWS, a term applicable to a code of laws calculated to preserve to certain qualified persons the exclusive privilege of sport in the destruction of the wild animals coming within the definition of game. It is perhaps, among all the social peculiarities of this country, that which retains in its present observance the most remarkable characteristics of its feudal origin. As the privilege of an extensive class, it appears to have no parallel in other social systems. Possibly it might be found that in many countries war against wild beasts, like war against foreign nations, was under the administration and control of the rulers of the people. It is as a well-guarded privilege of the sovereign's office that we find the earliest restraints in the pursuit of wild animals in the feudal laws. The spirit of this restrictive privilege could not be better expressed than in Manwood's definition of a forest, as "a certain territory, or circuit of woody grounds and pastures, known in its bounds, and privileged for the peaceable being and abiding of wild beasts and fowls of forest chase and warren, to be under the king's protection for his princely delight." In the Anglo-Saxon law, while the pursuit of game is treated as a mere adjunct of the possession of land, there are very special precautions against infringements of the monarch's right. In the secular ordinance of king Canute is this provision: "And I will that every man be entitled to his hunting in wood and in field on his own possession. And let every one forego my hunting: take notice where I will have it untrespassed on, under penalty of the full 'wite.'"[1] The progress made by the Norman kings in the establishment of hunting grounds, protected by cruel forest laws, is a portion of constitutional history involved in much doubt and dispute. Taking as an admitted point that pursuing wild animals was originally a royal privilege, Blackstone, in his Commentaries, gives a sketch of its extension to the landed gentry in a spirit strangely at variance with his usual laudation of existing institutions. Alluding to the royal privilege, he says,—"From this root has sprung a bastard slip known by the name of the game law, now arrived to and wantoning in its highest vigour, both founded upon the same unreasonable notion of permanent property in wild creatures, and both productive of the same tyranny to the commons; but with this difference, that while the forest laws established only one mighty hunter throughout the land, the game laws have raised a little Nimrod in every manor" (Com. iv. 416). To adjust the system to his general theory in English law, Blackstone presumed game to be property, and represented the monarch as possessed of the ultimate property in all feudal lands, retaining this right to himself, or communicating it to those whom he favoured. But all efforts to find a practical support for this subtle theory have only tended to show that the monarch arrogated to himself a monopoly in the higher class of field sports, because it was his will, and he had the power to do so; and that at a later period the landed gentry claimed a monopoly in the sports of the field for a similar reason. By the act of 13th Richard II., cap. 13 (1389), the possession of property was made a specific qualification for the privilege of killing game, and it was enacted that "no manner of artificer, labourer, nor any other layman, who hath not lands and tenements to the value of forty shillings by the year, nor any priest nor other clerk, if he be not advanced to the value of ten pounds by the year," shall keep hunting dogs, or use other methods of killing game, upon pain of one year's imprisonment.

The extent and character of the property qualification were modified from time to time during succeeding reigns. In Scotland, an act of the year 1600 (cap. 23) protests, in a true sportsmanlike spirit, against the slaughter of wild animals by the most effective means, and their sale by persons having regard to gain, and commodity to those who seek "their own inordinate appetite and gluttony." Hawking is the method of sport deemed legitimate by this act, and among the illegitimate methods of slaughter it is curious to perceive the accepted methods of the present day, by "hagbut" or fowling-piece, and "fowler dog," held as "indirect means," and "specially forbidden." The authors of this act seem to have placed their chief reliance on the withdrawal of game from legitimate commerce; but twenty-one years afterwards the English property qualification was adopted, in a very brief act, which simply enacts "that no man hunt nor hawk at any time hereafter who hath not a plough of land in heritage, under the pain of ane hundred pounds." The extent of the "plough of land" was a practical question down to very late times. In fact the "landed qualification" still exists in Scotland, so that nominally the sports of the field are a privilege exclusively enjoyed by those who possess landed property in the country. In practice, however, the offensive character of the rule, as conferring a privilege on a class, is modified by the presumption that he who has permission from a landowner to sport over his property is invested with the owner's qualification. In England the qualification from estate was abolished in 1831. Above forty years previous to that date (25th Geo. III., cap. 50) the enjoyments of the sportsman were considered a legitimate object of taxation, and the payment of a license-duty became the virtual qualification. The act of 1831 (1st and 2d Will. IV., cap. 32) is the leading statute on this subject, and contains the main substance of the English game law, enumerating the animals that come within its scope, adjusting close times and other restraints on the pursuit of game, limiting the commerce in dead game, and defining the special arbitrary powers necessary to the enforcement of the system. The general tenor of this act was followed in a general game act for Scotland (2d and 3d Will. IV., cap. 68). So lately as the year 1844 the peculiar restraints of the game law were extended by an act (7th and 8th Vict., cap. 29) directing many of the penalties of the trespassing poacher against unqualified persons pursuing game at night in the highways, and around the gates of inclosed places. A slight modification of the game laws, much solicited by farmers, was adopted in 1850, when the right of killing hares without a qualification was conceded to those who could do so without trespass or breach of contract.

---

[1] Mr Thorpe's Translation in *Record Commission's Ancient Laws and Institutes*, i., 421.

As a peculiar feature in modern European jurisprudence, game laws have arisen out of the desire to preserve, in the midst of cultivation and civilization, the pursuits by which in earlier stages of society men sought their immediate subsistence, or opened the way to civilization by clearing the wilderness of its dangerous inhabitants. It has hence been an unfortunate peculiarity of such a code of laws that, directed to the support of conditions antagonistic to material progress, to produce the desired effect they require to be rendered more complex and rigid as cultivation and population advance. On the American prairie the most ardent game-preserver would scarcely dream of any restraint on the pursuit of the noblest beasts of the chase, while in highly cultivated England small birds are protected by armed bands of gamekeepers. In some of the remote parts of Scotland it has been in the present century deemed meritorious to entrap and kill a fox, while in the hunting districts of England such an act would be counted a deed of the most atrocious character, as the wanton destruction of an element of high enjoyment.

The social influence of a game law is so deeply interwoven with class prejudices and political feelings at the present day that it cannot be impartially appreciated. On the one side, it cannot be disputed that a vast amount of that punishment which should be awarded solely to guard the public from crime is inflicted for offences against the game laws, and that there are many afflictive punishments which would not have been necessary had no such laws existed. It is maintained, that in addition to the direct infliction thus imposed on society, the system is a sort of inclined plane, facilitating the progress towards other acts undoubtedly criminal. It is a necessary peculiarity of a game law that what it protects is not *property* but a *privilege.* The laws for the protection of game have their peculiar character from the impossibility of separating and appropriating the wild animals to which they apply, as ordinary common possessions are separated and appropriated. Hares, partridges, and grouse may be said to belong to the general body who are by law entitled to slay them, but no member of the class can claim any of them as his own property. The owner of extensive preserves can maintain that the birds he shoots within them are the growth of his property, and have been fed at his expense; yet he is not entitled to reclaim those which fly into his neighbour's preserves, as he might reclaim his sheep, his dogs, or his domestic fowls. Hence the principle of the law itself countenances the peasant who denies that game is property, and who, as a consequence, refuses to brand the poacher with the infamy of the thief. Thus that love of sport and adventure so much commended among the superiors whom he is taught to respect, makes the peasant suddenly find himself a criminal at war with the laws of the land, who, even if he be not directly contaminated by association in prison with thieves and housebreakers, cannot be expected to retain the same horror of the baser crimes which he may have felt before he was stamped as an offender. It is another unfortunate peculiarity of these laws, as the protection not of property but a privilege, that they cannot be enforced without arming man against man, and producing conflict and bloodshed. A piece of property which can be identified is an enduring silent witness of the crime by which it may have been removed from its owner. Hence, though it may be desirable to catch thieves and housebreakers in the act, it is not indispensable; but the produce of poaching, which is no one's property, is not thus capable of identification. The evidence of the crime is the capture of the committer of it in the act, and hence has arisen an armed game police, acting, not under public responsible authority, but commanded in each instance by their private employers and the owners of the soil. Farther still, the difficulty of proving the offence after it has been committed has suggested the necessity of attacking it in its preparatory steps. The laws for the protection of property only require to adopt this alternative in a few classes of crimes accomplished by distinct stages, as forgery and coining, where the preliminary process of preparing plates or instruments is made criminal. It has not been found necessary to punish persons for making arrangements to commit a housebreaking, or even starting on an expedition to accomplish it. But the evidence of each act of poaching is so fugitive, that a vigilant system of penal checks guards the progress towards it; and trespasses, or other actions in themselves even less culpable, become punishable as taking place with the intent to kill game. It is a farther aggravation of this necessary defect, that the fact of *intention*, so readily believed by a partial judge, but so difficult of proof to an impartial one, is decided on and punished like all other offences against the game laws by members of the class whose prejudices, if not their interests, favour a stringent application of the restrictive provisions of the code.

On the other hand, it is said that the sportsman, in the pursuit of game, experiences a legitimate enjoyment which ought to be protected, even at some cost to the community; that the sports of the field are favourable to health, strength, and high spirit, and should be encouraged by a wise legislature, looking beyond the more sordid objects of human exertion. By persons who have less sympathy with sportsmen it is sometimes held, that in a country where there is much superfluous wealth it is a sound arrangement to find some factitious occupation or exciting recreation for its owners which may divert them from pursuits more dangerous to the peace of the community. It has been suggested, that if the principle of a qualification to kill game, and the consequent penal laws, were entirely abandoned, the destruction caused by the extensive invasion of landed property which would follow the general license to extirpate game would render necessary new and stringent laws of trespass afflicting a more inoffensive class of people than those checked by the laws which suppress poaching, and tending to suppress the innocent recreations of the community. It is said farther, that the privilege of following field sports no longer conveys the stigma of feudal subjection to those who do not enjoy it, since virtually it is open to purchase, and consequently all who by their industry and prudence succeed in obtaining wealth may procure it like any other luxury. In answer to those who rail at shooting as a destructive pursuit, wasteful of the produce of the soil, it is said that the owners of sporting grounds bring them into condition for a solid rent from tenants who, after enjoying the pursuit of the game, sell it in the best market. Should the force of such reasons be admitted against the entire abolition of a game law, the question remains, how far the existing game laws of the British empire are consistent with the general welfare of the community. (J. H. B.)

GAMELIA, in *Grecian Antiquity*, the presents given to a bride on the eve of her marriage, when she was introduced by her parents or guardians to the members of the phratria to which her intended husband belonged. The ceremony of enrolling newly married women in the lists of their adoptive phratria was also called Gamelia. The object of this enrolment was to exclude strangers from participating in those rights of Greek citizenship to which they had no legal title. It also guaranteed the legitimacy of the children of persons who went through the necessary forms, and the validity of their claims to all the rights and privileges of citizens.

GAMELION, the seventh month of the ancient Athenian year, containing thirty days, and corresponding to our January; or, according to some, to the latter part of January and the begining of February. It was thus named because it was a favourite time for marriages.

GAMES, Public, in *Antiquity*, were contests and spectacles of various kinds, which in the earlier ages at least were intimately connected with religion. The Grecian games were very numerous; and they are traceable by tradition back to the earliest periods of Grecian civilization. Indeed, much of the obscurity which rests on their origin is a consequence and a sign of their high and even mythic antiquity.

Of these, the most celebrated were the Olympic, the Pythian, the Nemean, and the Isthmian games, which were distinguished by the appellation of ἱεροί, "sacred." The victors at the Olympic games were accounted the noblest and happiest of mortals, and all means were taken that could show the respect in which they were held. These games were celebrated every five years at Olympia, in Elis, on the west side of the Peloponnesus. Hence the epoch called the Olympiads.

The gymnastic exercises were laid down in a well-planned systematic series, beginning with the easier, and proceeding to the more difficult. Some of these were specially fitted to give strength, others agility; some educated the hands, others the feet. Among the lighter exercises were reckoned running, leaping, quoiting, and hurling the javelin. When skill had been obtained in these, and the consequent strength, then followed a severer course of discipline. This was twofold—simple, and compound. The simple consisted of wrestling and boxing; the compound we find in the *Pentathlon* (the five contests), and the *Pankration* (or general trial of strength). The Pentathlon was made up of the union of leaping, running, quoiting, wrestling, and hurling the spear; the Pankration consisted of wrestling and boxing.

Racing may be traced back to the earliest periods of Grecian antiquity, and may be regarded as the first friendly contest in which men engaged. Accordingly the Olympic and Pythian, probably also the other games, open with foot-races. Foot-racing, perfected by systematic practice, was divided into different kinds. When the distance was merely to the end of the course (στάδιον), it was called stadium; if thither and back, it constituted the double course (δίαυλος). The longest course was the δόλιχος, which required extraordinary speed and power of endurance. What it involved the ancients have left in no small uncertainty. It is sometimes given as seven times over the stadium; at others, twelve times; at others again, twenty; and even the number of four-and-twenty times is mentioned. These distances will give some idea of the severity of the trial. Indeed one Ladas, a victor at the Olympic games, was so exhausted by his efforts in the long race, that immediately on gaining the honour and being crowned, he fell dead. In the preparatory discipline everything was done which could conduce to swiftness and strength. The exercises were performed with the body naked and well oiled. Minute directions were established in order to prevent foul play of any kind, so that all the competitors might start and run on terms of entire equality. A passage in the *Enchiridion* of Epictetus will serve to show how rigid was the preparatory discipline: "You wish to conquer at the Olympic games? so also do I; for it is honourable; but bethink yourself what this attempt implies, and then begin the undertaking. You must subject yourself to a determinate course; must submit to dietetic discipline; must pursue the established exercises at fixed hours in heat and cold; must abstain from all delicacies in meat and drink; yield yourself unreservedly to the control of the presiding physician, and even endure flogging." It may well be supposed that the competitors employed all their ability, and displayed the greatest eagerness to gain the prize. The nearer, too, they approached to the goal, the more did they increase their efforts. Sometimes the victory depended on a final spring; happy he that retained power enough to leap first to the goal. The spectators also used every encouragement in their power, these favouring one competitor, those another:—

> "Verbaque dicentum, nunc, nunc incumbere tempus,
> Hippomene, propera. Nunc viribus utere totis."

Statius (*Theb.* vi. 587) has given a lively picture of some of the practices by which the runners endeavoured to give suppleness and agility to their limbs:

> tunc rite citatos
> Explorant, acuuntque gradus, variasque per artes
> Exstimulant docto languentia membra tumultu.
> Poplite nunc flexo sidunt, nunc lubrica forti
> Pectora collidunt plausu; nunc ignea tollunt
> Crura, brevemque fugam necopino fine reponunt.

After the competitors had been called into the lists by the herald, they sometimes tried their strength and exercised their frames by running out and back on the course. Virgil (*Æn.* v. 376) represents Dares as displaying the size and flexibility of his arms prior to his combat with Eryx:

> Ostenditque humeros latos, alternaque jactat
> Brachia protendens, et verberat ictibus auras.

Corinth was the place where the Isthmian games were celebrated; and these were so called from being held on the isthmus which joins northern with southern Greece—a spot of land most celebrated in Grecian history, alike in martial and commercial matters. In the narrowest part of this tongue of land, between Lechæum and Schœnus, stood the famous temple, sacred to the Isthmian Neptune. It was shaded by a pine grove. Here began the Isthmian games. Here also was a splendid theatre, and a race-course adorned with white marble. Other distinguished works of art adorned and hallowed the vicinity.

If we attempt to trace these games to their origin we are lost in the mists which envelope the mythical periods of the Greek national life. They were obviously connected with the worship of Neptune; the wide diffusion of which tended greatly to secure for the Isthmian games the great celebrity which they enjoyed, calling, as they did, competitors and spectators from all parts. The Persian war gave a new impulse to the Isthmian games. The Peloponnesian war, on the contrary—as being a contest of Greek against Greek—dimmed their glory, and abated their influence. Even when, at a later period, Corinth became a Roman colony, the games, so far from losing their importance, were exhibited under the Cæsars with an increased celebrity. They were held every three years, and comprised three leading divisions—musical, gymnastical, and equestrian contests. In the first the tyrant Nero carried off a crown, by destroying his too highly-gifted antagonist. The gymnastic contests were of the same kind in all these games. A few words may here be introduced as to the horse-racing, of which the same kinds prevailed at the Olympic, the Pythian, and the other sacred games. Chariot-races seem to have been practised in the earliest heroic times, since chariots were as early as this used in battle, and the notices which have come down to us refer this kind of sport to the early period now indicated. It stood pre-eminently before other games. The skill and outlay which it required prevented any but persons of distinction—the wealthy, governors, princes, and kings—from engaging in its enjoyments. The Homeric competitors made use in their games of their two-horsed war-chariots, which they occupied each one alone, and drove themselves, though in battle it was not unusual for the reins to be entrusted to a charioteer. In the heroic ages these contests opened the games. To them belonged the highest prizes. In the Olympic games horse and chariot racing gradually branched out into different kinds. So much importance was attached to these games that historians have recorded the exact time when particular kinds were first introduced, and immortal poets sung the praises alike of the victors and their horses. The four-horsed chariot-race had its origin in the 25th Olympiad. In the 93d Olympiad was held the first contest with two-horsed chariots. Foals were now made use of, as well as horses. For a time mules also were employed. Other varieties, mostly designed for a display of skill and splendour, came and went as fashion dictated. The number of chariots that might appear on the course at once cannot be accurately determined. Pindar (*Pyth.* v. 46) praises Arkesilas of Cyrene for having calmly brought off his chariot uninjured, in a contest where no fewer than forty took part. The course had to be gone over twelve times. The urgency of the drivers, the speed and exhaustion of the horses, may easily be imagined. The greatest skill was needed in turning the pillar which marked the extremity of the course, especially when the contending chariots were numerous. How to avoid the danger of collision, how to turn as near the pillar as possible, so as to save ground, were points of the greatest consequence, as Sophocles in his *Electra* intimates (West's Trans.),

Th' Athenian, with consummate art,
His course obliquely veered, and steering wide
With steady rein, the wild commotion pass'd
Of tumbling chariots and tumultuous steeds.

At the Olympic games the prize was simply a chaplet of wild olive. The crowns were laid on a tripod, and placed in the middle of the course, so as to be seen of all. On the same table there were also exposed to view palm-branches, one of which was given into the hand of each conqueror at the same time with the chaplet. The victors, having been summoned by proclamation, were presented with the ensigns of victory, and conducted along the stadium, preceded by a herald, who proclaimed their honours, and announced their name, parentage, and country. The real reward, however, was in the fame which ensued. A chaplet won in the chariot-races at Olympia was the highest of earthly honours. What congratulations from friends; how was the public eye directed to the fortunate conqueror; what honour had he conferred on his native city, and for what office was such an one unfit! What intense and deep delight must his bosom have been filled with when the full acclaim of assembled Greece fell upon his ear, coming in loud salutations and applauses from every part of the crowded course! Then came the more private attentions of individual friends. One brought a chaplet of flowers; another bound his head with ribbons. Afterwards came the triumphal sacrifice made to the twelve gods, accompanied by sumptuous feasting. The poet now began his office, gaining, in some cases, both for himself and the happy victor an unexpected immortality. Music also lent her aid, and his name was sung wherever the Greek language was spoken. In order to perpetuate the memory of these great men, their names and achievements were entered in a public register, which was under the care of suitable officers. A no less privilege was that of having a statue of themselves placed (either at the expense of their country or their friends) in the sacred grove of Jupiter. A perhaps still greater honour awaited the victor on his return home. The conquerors at the Isthmian games were wont to be received in their chariots, superbly attired, amid thronging and jubilant multitudes. One or two other privileges belonged to these victors, such as immunity from public offices, and a certain yearly stipend. If to all this be added the strict scrutiny which competitors were obliged to undergo (in the best ages), so that none could enter the lists but such as were of pure Greek blood and incorrupt in life, none but such as had undergone the required disciplinary training, and (in the case of the chariot and horse races), none but those who could afford to possess and train horses in a country in which, as in Greece, horses, particularly in the earlier ages, were very scarce and dear—it will be seen that the distinction of the prize was not over-rated when it was compared with a Roman triumph, nor that the description of Horace is too highly coloured—

palmaque nobilis
Terrarum dominos evehit ad Deos.

At the Isthmian games the prize was parsley during the mythic periods. In later ages the victor was crowned with a chaplet of pine leaves. Parsley, however, appears to have been also employed. If the conqueror had come off victorious in the three great divisions—music, gymnastics, and racing—he was in the Pythian, as well as in the other sacred games, presented also with a palm branch. The names of about seventy persons are preserved who gained honours at the Isthmian games, among which occurs that of the emperor Nero, who is recorded to have gained the victory in the character of harper and that of herald.

These games, taken in connection with the early and long training by which they were preceded, and of which they were both the natural result and reward, were a grand educational system, bearing primarily indeed in favour of the physical development, but also tending directly and powerfully to advance the intellectual and moral culture. The exercises through which the child, the youth, and the man were stage by stage conducted, each in succession becoming more difficult and more complex, as the bodily powers came into play and acquired vigour, were admirably adapted to give that union of strength and beauty in which physical perfection consists, and in which the Greek nations probably surpassed every other known people. The existence of these exercises and these games in each separate state secured the development and activity of those feelings which made his own country to each one dear and venerable; while a narrow and selfish patriotism was greatly prevented, and emotions which embraced the whole Hellenic race were enkindled and fostered by those general meetings which from time to time called together, especially at

Olympia, all who were not aliens from the Greek commonwealth, marked out by the use of that noble instrument of speech, the Greek tongue.

Aware of the importance of the training in the gymnasium, Solon took the business under his special care, laying down minute regulations as to time, place, and extent, so that nothing might be left to chance or caprice. Then the school, in general, had its president—gymnasiarch—and each separate department a separate head; as in the case of the torch-race, which had its lamparchy, or government, charged with the office of making, in connection with it, all necessary arrangements. There were, however, two officers whose names and functions strikingly serve to show how greatly these Grecian institutions had a favourable influence on character: the first was the *kosmetes*, whose name comes from a word (κόσμος) signifying order and beauty, and whose office consisted in the special superintendence of everything fitted to further these high qualities; the other officer was termed *sophronistes;* and his business was still more intimately conducive to inform the mind, since, as his designation (from σώφρων) proves, he was required to guide the pupils to σωφροσύνη, a term for which we have no English equivalent, but which may perhaps be approximately rendered by "sound-mindedness." The elder Athenians were so solicitous to give a right direction to the influence of the gymnasium, the palæstra, and the stadium, that they annually elected ten sophronists (one out of each tribe), and the honour which was attached to the office may be learnt from the fact that in some inscriptions their name stands before that of the gymnasiarchs themselves. The usual province of the sophronists extended beyond the limits of the exercise-grounds, for they exercised over the youth a general legal oversight. Even their play-hours were under the eye of the sophronist. When the young men joined in the solemn procession of the grand national Panathenæa they were under the guardianship of the sophronists. Were they present at the nocturnal festival held in honour of Hebe, they were still attended by and subject to their sophronist. That something even of a sacred character belonged to these preparatory exercises appears from the fact that the kosmetes bore also the designation of ἱερεύς (priest), having charge of certain sacrifices.

Were there no other consideration in their favour, yet the severe examination to which candidates for admission to these contests were compelled to submit, would suffice to prove that the general tendency of the games was good. Besides being questioned as to their condition—were they freemen or slaves?—and as to their blood—were they really Greeks?—they had also to satisfy their judges that their characters were free from moral stain. In the public stadium the herald, laying his hand on the head of the candidate, inquired with a loud voice, "Can any one accuse this man of any crime? Is he a robber or a slave? or wicked or depraved in his life?" If he successfully passed this ordeal, the candidate was then conducted to the altar of Jupiter, the punisher of the perjured, where with solemn rites he was required to swear (if he could with truth and safety) that he had gone through the required preparatory course of discipline, and would abstain from every breach of the laws in the contest before him. (On the subject here treated of see Krause's *Die Gymnastik und Agonistik der Hellenen;* and his *Die Pythien, Nemeen und Isthmien.* Leipzig, 1841.)

Among the Romans, the amusements of the circus did not materially differ from the Greek *agones* or contests celebrated at Olympia, Delphi, and elsewhere, and were certainly of a nobler kind than the frightful gladiatorial fights of the amphitheatres, though sometimes a circus also was polluted by these inhuman exhibitions. The θηριομαχία, or beast-fight, was a favourite species of entertainment with that people; and the persons destined to this barbarous kind of amusement were termed *bestiarii.* They were generally of two classes—1st, voluntary, that is, persons who fought either for amusement or for pay: these were clothed and provided with offensive and defensive weapons; 2d, condemned persons, who were mostly exposed to the fury of the animals unclothed, unarmed, and sometimes bound. As none but the vilest of men were in general devoted to these beast-fights, no punishment could be more ignominious and cruel than what was frequently inflicted on the primitive Christians when they were hurried away "to the lions," as the phrase was.

Of these beast-fights the Romans were passionately fond; and the number of animals which appear to have been from time to time engaged in them is extraordinary. Sylla, during his prætorship, sent into the arena no fewer than 100 lions, which were all slain. Pompey caused the destruction in this way of 600 lions. On the same occasion nearly 20 elephants perished. These numbers, however, are small compared with the slaughter which took place in later periods. Under Titus 5000 wild and 4000 tame animals, and in the reign of Trajan 11,000 animals, are said to have been destroyed. (See also AMPHITHEATRE, and CIRCUS.)

GAMMONING, among seamen, the lashing by which the bowsprit is secured to the cut-water

GAMMUT, signifies a musical scale, of which the lowest sound is G, marked by the Greek Γ, or *gamma.* Such was the scale given by the monk Guido d'Arezzo in the eleventh century, although he expressly says that it was used before his time. From *gamma* we have the French *gamme*, a *scale* in music. (G. F. G.)

GAMONEDA, a mountain-chain of Spain, on the mutual confines of Castile and Galicia, to the east of the Sierra de Marabon, from which it is separated by the river Tuela. It is a continuation of the range which extends to the E. about 12 miles under the same name, and parallel to the Sierra Segundera. The Gamoneda is very well known from its immense elevation, and its entire mass is composed of loose heaps of stones and solid rocks, interspersed with seams of slate and other minerals, exactly similar to the Sierra de Segundera.

GANDESA, a town of Spain in the province of Cataluña and bishopric of Tortosa. It is situated in an open country surrounded with elevated hills, and is encircled by a wall which is entered by four gates. It is 50 miles W.S.W. of Tarragona, and contains 2316 inhabitants.

GANDHARBA, or GANDHARVA, a species of demigods or angels, the musicians of heaven, inhabiting Indraloka, the paradise of the Hindu deities, and witnesses of the actions of men. They are 60,000,000 in number. In the creation of the second Manwantara they are called the children of Arishtá and Kashyapa (whence they are sometimes called Mauneyas, children of Muni, namely, Kashyapa). By them the Nagas, or mythological serpents in the regions below were despoiled of the jewels which decorated their heads. They applied to Vishnu, who sent Purukusta to Pátála to destroy the Gandharbas. Originally they belong to the latter Epic period, but figure more prominently in the *puránas.* [No satisfactory etymology has yet been proposed for this name. One given in the Vishnu Purána is *gan dhayantas, i.e.,* "suckling the goddess of speech;" and another equally ridiculous is that in Wilson's Sanscrit Dictionary—*ganda*, "smell," and *arb*, "go," alluding to the musk-deer for which this word is a name. Its primitive meaning was probably that of some singing bird. The sense of Koïl, or Indian cuckoo, is attributed to it in the *Medino Kosha.*]—*Bhagavad-gítá*, by J. C. Thomson, 1855.

GANDIA, HUERTA DE, a district of Spain, in the province of Valencia, and one of the most valuable not only in Spain, but in all Europe. It bears the form of a horse-shoe, bounded by a chain of beautiful hills, some of which attain a considerable elevation; and opens towards the east upon the blue waters of the Mediterranean. The two ends of the horse-shoe are, on the south, the eastern cape of Mostalla, and on the north, the Hill of Bayreut. In the immediate neighbourhood of the sea the soil is very sandy, sterile, and often inundated; but inland it becomes extremely fertile, and enjoys the finest climate imaginable, not cold in winter, and tempered during spring, summer, and autumn, by refreshing breezes from the Mediterranean. This rich district contains the city of Gandia, and twenty smaller towns, some in the plains and others along the skirts of the hills, all visible from the spire of the principal church, or the hermitage of Santa Ana.

Gandia, a secular city of Spain, in the province and archbishopric of Valencia. It is very beautifully situated in the Huerta de Gandia, and contains nearly 8000 inhabitants. It stands near the Mediterranean Sea, and contains a fine collegiate church, a college, and a palace of the duke of Gandia. It is noted for the manufacture of silk, linen, and sugar.

GANGES. This great river has its rise in the southern face of the Himalaya Mountains, and after a course of between 1500 and 1600 miles falls into the Bay of Bengal through two principal channels, widely separated from each other; the one known as the river Hooghly, which flows by Calcutta in its passage to the bay of Bengal; the other, further to the eastward, termed the Podda, or Ganges, and subsequently the Megna, which finds its way to the sea through the Sunderbunds. The remote sources of the Ganges were long imperfectly known, and afforded a fertile subject of conjecture and controversy to the geographers of Europe. Prior to the commencement of the nineteenth century this river, designated the Bhageerettee in the upper part of its course, had been traced by Hindu pilgrims to Gangootri, the point at which it issues from the Himalaya mountains; but all accounts agreed that its origin was still more remote. On the side of Thibet it was reported to have been surveyed by lamas or priests, sent for that purpose by the Emperor Camhi, whose route terminated at Rentaisse, a range of snowy mountains on the west and south of Thibet. The most general notion was that it flowed within the Himalaya chain of snowy mountains for many hundred miles from the imaginary lake of Mapama to Gangootri. In 1808 Lieutenant Webb was sent by the Bengal government to explore the sources of the Ganges. About 17 miles beyond Gangootri his further progress was stopped by the difficulties of the country, but the Moonshee who accompanied the party went forward; and as he proceeded upwards after leaving Gangootri, he occasionally perceived the river among the snow, which, a little higher up, so completely filled its bed that no trace of it could be discovered. Five hundred yards farther on it again showed itself; but in front was a steep mountain rising up like a huge wall, from an angle of which the Ganges appeared to issue, whilst all beyond was an impenetrable mass of snow. This is the furthest point to which the Ganges could then be traced. Subsequently, however, it has been clearly established that the most remote feeder of the Bhageerettee, or Ganges, derives its origin in British territory, and from a locality situate on the southern instead of the northern base of the Himalayas. Ten miles above Gangootri the Bhageerettee, or Ganges, first comes to light at a place called the Cow's Mouth. It is a large stone in the middle of the stream, the water passing it on each side, and leaving only a small piece above the surface, to which the fancy of superstition has given the form of a cow's head, an animal held sacred by the Hindus. From Gangootri the Ganges flows among the mountains from S.E. to N.W. to Bhairogathi, where it is joined by the Jahnuvi, its most distant feeder, and to which the title of originating the waters of the Ganges must now be awarded. The pretensions of the Doulee to this distinction have been asserted; but as the distance from the source of that river to its confluence with the Ganges at Deoprag falls short of the distance measured from the latter spot to the source of the Jahnuvi, the grounds upon which its rival claims have been advanced cannot but be regarded as insufficient. From Sookie, where it fairly pierces through the Himalaya Proper, the river assumes a course S.W. to Hurdwar. Here, in the latitude of 29. 57. N., it gushes through an opening in the mountains and enters the plains of Bengal. From Hurdwar to its conflux with the Jumna at Allahabad it is described as a stream of shoals and rapids, but navigable for river craft. The inland navigation of this portion of India will be materially improved by the Great Ganges Canal, now (1855) rapidly advancing to completion, and which was undertaken with the twofold object of affording increased means of irrigation to the north-western provinces, and adding to the facilities of water transit. The canal issuing from the river at Hurdwar traverses the Doab to Allyghur, whence it diverges in two channels, one leading to the parent stream at Cawnpore, and the other to Humerpore, with several offsets to other districts. The total length of this canal, with its branches, measures upwards of 800 miles, and is estimated to cost a million and a half sterling. (See also Aqueduct.) With the exception of the Ramgunga flowing from Rohilcund, the Jumna is the first large river that joins the Ganges after it debouches from the hills. From its arrival in the plains of Hurdwar, to the conflux with the Jumna, its bed is of unequal depth, and its course, compared with the latter part, tolerably straight. From hence downwards it becomes more winding, till having successively received the waters of the Goggrah, the Soane, and Gunduck, besides numerous smaller streams, its bed attains its full width, which, though very unequal, is estimated to average a mile in the dry season on its whole course through the plains, and two miles in the freshes. At the height of the inundation the breadth of the river in some parts of its course is enormous. Bishop Heber mentions that at Boglipoor, about 600 miles from the sea, including the turnings of the river, the breadth in one year at this season was 9 measured miles, and 7 in the following season. Though the Ganges be fordable in some places above the conflux of the Jumna, the navigation is never interrupted for small craft up to Hurdwar, or for river steamers conveying passengers and treasure as far up as Ghurmuktesur, a town on the river, situate about 100 miles below Hurdwar. Below the confluence the channel is increased, the additional streams bringing a greater accession of depth than breadth; yet so shallow in places is the stream during the dry season, that, according to the author of the work entitled *Steam Navigation in British India*, craft should have a draught little exceeding 18 inches to navigate safely and beneficially between Calcutta and Allahabad. At about 220 miles from the sea, or 300 reckoning the windings of the river, commences the head of the Delta of the Ganges. The two westermost branches named Cossimbazar and Jellinghy rivers unite and form what is afterwards denominated the Hooghly, which at Diamond Harbour forms the port of Calcutta. The length of course of the Ganges from its most distant source to the sea by this channel measures 1514 miles. Below the channel where the Ganges sends off these two branches to Calcutta, the main stream loses not only its name, but the greatest part of its sanctity in the eyes of the natives. The Cossimbazar river is almost dry from October to May, nor is the Jellinghy navigable during two or three of the driest months; consequently, at that period the communication by water between Calcutta and the Ganges above the Delta is maintained by a circuitous course termed the Sunderbund passage. That part of the Delta called the Sunderbunds consists of a labyrinth of rivers and creeks, measuring about 160 miles in breadth between the Hooghly and the Megna, the two principal channels of the Ganges, at their junction with the sea. This tract is covered with woods, which are infested with tigers, and its numerous canals form a complete inland navigation across the lower part of the Delta. The Ganges, like all tropical rivers, overflows periodically during the season of the rains in Bengal, on which it depends for its supplies, and not, as may be supposed, on the melting of the mountain snows. Its rise commences late in May, and reaches its maximum in September, at which period it attains the increased height (independently of the tide) of about 7 feet at Calcutta, and from 30 to 45 feet at Benares and Allahabad. In October the waters of the Ganges rapidly subside, after which scarcely a shower falls in the long dry season of Bengal. According to Rennell the quantity of water discharged by the Ganges is calculated in the dry season to amount to 80,000 cubic feet per second, and during the inundation to 405,000 cubic feet, giving a medium for the whole year of 180,000 cubic feet. Results widely differing in the extremes of both seasons have been obtained from experiments made at Benares and Sicrigally, from which it would appear that the mean discharge throughout the year averages 250,000 cubic feet at Benares, and double that quantity at Sicrigally. The descent of the river from Allahabad to Benares has been estimated at 6 inches per mile; from Benares to Colgong at 5 inches per mile; from Colgong to Jellinghy at 4 inches per mile; from Jellinghy to Calcutta at 4 inches; and from Calcutta to the sea at from 1 to 2 inches. In the dry season the current flows at the rate of 3 miles per hour; it increases during the wet season to 5 or 6 miles, and in particular situations to 7 or 8 miles. On the banks of the Ganges, where the soil is loose and the current rapid, "such tracts of land," says Major Rennell, "are swept away in one season as would astonish those who have not been eye-witnesses to the magnitude and force of the mighty streams occasioned by the periodical rains of the tropical regions." Great changes are in this manner produced in the course of the river; what is lost on one side being gained on the other by the mere operation of the stream. In its course through the plains the Ganges receives eleven rivers, some of which are larger than the Rhine, besides many others of less importance. The Jumna, Goggrah, Soane, and Coosy, are the largest of its tributary streams. The Brahmapootra has its rise near the source of the Ganges, and from hence the two rivers diverge widely asunder, but afterwards they intermix their waters before they fall into the sea, the Ganges having then performed by this channel a course, including its windings, of about 1570 miles. (E. T.)

GANGOOTRI, a celebrated place of Hindu pilgrimage, situated among the Himalaya Mountains, in the native Raj of Gurwhal, on the Ganges, which is here not above fifteen or twenty yards broad, with a moderate current, and not in general above three feet deep. The course of the river is here N. by E.; and on the bank near Gangootri there is a small temple about eight or ten feet high, in which are two images representing the Ganges and Bhageerettee rivers. The bed of the river adjoining the temple is divided off by the Brahmins into three basins, where the pilgrims bathe. One of these portions is dedicated to Brahma, the other to Vishnu, and the third to Seva. The pilgrimage to Gangootri is considered as a great achievement of Hindu piety, to be efficacious in washing away all the previous sins of the devotee, and ensuring him eternal happiness in the world to come. The water taken from this sacred spot is exported by pilgrims to India, and sold at a high price. It is drawn under the inspection of a Brahmin, to whom a trifling sum is paid for the privilege of taking it; and the vessels are then sealed. The elevation of the temple above the sea is 10,319 feet. Long. 78. 59. E., Lat. 30. 59. N.

GANGPOOR, a raj or petty native state of Hindustan, province of Gundwana, situate about the 22d degree of north latitude, and bounded on the N. by the British district of Chuta Nagpur. Area, 2493 square miles. Pop. 112,000. It is a barren, mountainous, and unproductive country, inhabited by uncivilized tribes of Hindus. The chief river is the Soank, and the principal town is Gangpur, situate in Lat. 22. 3., Long. 84. 43. (E. T.)

GANJAM, a town and seaport of Hindustan, in the Northern Circars, and capital of a cognominal district. It is situated on the N.E. bank of a river navigable only during the rainy season, when a great part of the surrounding country is inundated. It possesses a fort, which is a regular pentagon on plain ground, well fortified, and capable of making a respectable defence. This port is much frequented by country vessels. The district of which this town is the chief place is bounded S.E. by the Bay of Bengal, and on all other sides by the territory of Orissa. Area estimated at 6400 square miles: Pop. 926,930. The whole district is included within the territory called the Northern Circars, the possession of which was wrested from the French by Clive in 1759. The town of Ganjam is in Lat. 19. 23., Long. 85. 7. (E. T.)

GANNAT, a town of France, capital of a cognominal arrondissement, department of Allier, on the right bank of the Andelot, an affluent of the Allier, 33 miles S. by W. of Moulins. It was formerly surrounded by walls, and what remains of its old castle is now used as a prison. The vicinity is very pleasant, but the town itself is ill-built. It has an hospital, a tribunal of primary instance, and some trade in corn, wine, and cattle. Pop. (1851) 5349.

GANNET. See index to Ornithology.

GANTLET, or Gauntlet (Fr. *gantelet*, from *gant*, a glove), a kind of iron glove, with fingers covered with small plates; formerly worn by cavaliers when armed at all points, and which used to be thrown down as token of challenge. Gauntlets were introduced about the 13th century.

GANYMEDES, in *Grecian Mythology*, a Trojan youth of surpassing beauty, who was carried off by Jupiter to supplant Hebe in the office of cup-bearer to the gods. The king of gods and men presented Tros with two divine horses as a compensation for the loss of his son, who himself was honoured with an immortality of youth. Ganymede is generally represented in works of art as a young man in the first bloom of youth, and wearing the Phrygian cap. At other times he is in the act of being carried off by the eagle of Jove, or is feeding that royal bird from a dish.

GAOL. See Prisons.

GAOL DELIVERY. The administration of justice having been originally vested in the crown, the king in former times rode in person through the realm once in seven years, to judge and determine crimes and offences; but afterwards justices in eyre were appointed, and since that time justices of assize and gaol delivery. A commission of gaol delivery is a patent in the nature of a letter from the king to certain persons, appointing them his justices, or two or three of them, and authorizing them to deliver his gaol at a particular place of the prisoners in it; for which purpose it commands them to meet at such a place, at such time as they themselves shall appoint; and informs them, that for the same purpose the king has commanded his sheriff of the same county to bring all the prisoners of the gaol, and their attachments, before them at the day appointed.

GAONS, an order of Jewish doctors who appeared in the East after the closing of the Talmud. The word *gaons* signifies excellent or sublime; as in the divinity schools we formerly had irrefragable, sublime, resolute, angelic, and subtile doctors. The Gaons succeeded the Seburæans, about the beginning of the sixth century. Chanan Meischtia was the head of the "Excellents," and restored the academy of Pandebita, which had been shut up for thirty years.

GAP (the ancient *Vapincum*), a town of France, capital of the department of Hautes Alpes, and of a cognominal arrondissement, on the right bank of the Luie, 46 miles S.E. of Grenoble. It stands in a wide valley 2390 feet above the sea, and surrounded by an amphitheatre of hills, over which tower the snow-covered mountains of the Alps. In the vicinity are fine walnut avenues and vineyards, but the town itself is an ill-built miserable-looking place. The chief public buildings are the Gothic cathedral, containing the tomb of the celebrated Constable de Lesdiguières, the court house, town hall, bishop's palace, barracks, and theatre. It is the seat of a court of primary jurisdiction, and has a communal college, diocesan seminary, public library, and a museum of natural history. The manufactures comprise woollen, linen, and silk goods, leather and dressed skins. In the vicinity are some marble quarries, which were known to the Romans. It became the seat of a bishopric in the fourth century, and its bishops were for a long period styled princes and counts of Gap. Gap in former times suffered greatly from the devastations of the Lombards and Saracens, from earthquakes, the plague, &c., but more especially from the revocation of the edict of Nantes. Pop. of town (1851) 7726.

GARACHICO, one of the most important places in the island of Teneriffe till it was nearly destroyed by a volcanic eruption in 1705. It now contains about 2600 inhabitants.

GARAMANTES, in *Ancient Geography*, a Libyan race of North Africa, inhabiting the oases in the eastern part of the great desert, and separated from the Gætuli by the Mons Usargala. In a more limited sense, the name Garamantes was applied to the inhabitants of the great oasis of Phazania or Fezzan, a district of country which, though well sheltered against the sands of the desert, was neither well watered nor remarkable for fertility. The Garamantes were known to the Greeks, though somewhat vaguely. Herodotus describes their country as lying thirty days' journey from that of the Lotophagi, as fruitful in dates, and notable for its cattle, whose horns were so long and so bent forward that the animals had to feed walking backwards. Immediately adjoining the Garamantes, dwelt in caves a wretched negro race of wonderful swiftness of foot, whom their more powerful neighbours used to hunt down in chariots. Nothing new was ascertained about the Garamantes after the time of Herodotus till the Romans became masters of North Africa. In the year B.C. 19 Cornelius Balbus, a Roman proconsul, penetrated into their country, and overawed the towns on his line of march, which yielded a sort of temporary homage. He was rewarded with a triumph for his success, which, however, was rather nominal and temporary than real and permanent.

GARBE, in *Heraldry*, a sheaf of any kind of grain.

GARCILASO DE LA VEGA was descended from a noble family of Toledo, and was born in the year 1503. According to the romances, his father, who was counsellor of state to Ferdinand and Isabella, distinguished himself in single combat with a Moor on the Vega or *plain* of Granada; and thus was obtained, by royal appointment, the surname which distinguished the family.

The young Garcilaso gave early evidence of poetic talent, and had written several pieces in the old Castilian style, when he formed an acquaintance with Boscan, which soon ripened into friendship. Hence he was led to entertain new views of classical poetry, and to study Virgil and Petrarch with a special view to the improvement of pastoral poetry in his native language. But, though designed by his natural tastes for a rural life, it was his lot to follow the restless profession of arms; and the wars of Charles V. removed him from the home of his fathers, and dragged him from one country to another. In the year 1529 he distinguished himself as a member of the Spanish corps which repulsed the Turks in Austria. At Vienna he undertook to promote the marriage of his nephew with one of the ladies of the court, and thus drew on himself the displeasure of the emperor, whose dignity, it appears, was in some way compromised. He was, in consequence, banished to one of the islands of the Danube, and here he composed at least one of his canciones, bewailing his unhappy lot, but at the same time celebrating the praises of the majestic river, and describing the various countries watered by its streams. We hear of him again in 1535, when he was wounded in the adventurous expedition of Charles V. against Tunis. Thence he returned into Italy, and devoted himself, as far as circumstances permitted, to the composition of pastoral poetry. Bound by his profession to scenes of war which he hated, he solaced himself by employing his leisure hours in framing delightful pictures of Arcadian life, and embodying them in harmonious verse. Yet he seems to have possessed no inconsiderable share of military talent; for we find him in the command of eleven companies of infantry at the siege of Provence, when he could not have been more than thirty-three years of age. Towards the close of this partially unsuccessful campaign, he was ordered by the emperor in person to assail a fort, the garrison of which was harassing the retreat of the Spanish army. Garcilaso executed this commission with more zeal than prudence. Determined to be the first to scale the walls, he attained his object; but was struck on the head with a stone, and thrown from the ramparts. Being mortally wounded, he was removed to Nice, where he died a few weeks afterwards.

It would be difficult to discover from the works of Garcilaso that the author had spent an active and troubled life, almost constantly in the camp or the battle-field, and that he had died in the bed of military honour, the victim of his courage. He approaches even more closely than Boscan to the tenderness of Petrarch; and it is only by occasional characteristic traits that the Spaniard is recognised. It must be confessed, however, that when such passages do occur, the exaggeration is striking enough. Among his sonnets, which are thirty-seven in number, there are several in which we remark a sweetness of language and delicacy of expression which delight the ear, together with a mixture of sadness and of love, of the fear and yet the desire of death, betraying the strongest mental agitation. The translation of one of these sonnets, though it will give but a faint idea of Garcilaso's poetry, will yet afford a correct picture of Castilian love; a passion in which the fiercest warriors assumed a languishing tone and an attitude of submission:—

Si quejas y lamentos pueden tanto.

If lamentations and complaints have power
  To rein the rivers in their headlong course,
  To bow the trees as with resistless force
In lonely desert, glen, or darksome bower;
If chanted plaints of ills far less than mine
  Have charmed the savage tigers to attend,
  Have forced the rocks of hell an ear to lend,
And spell-bound Pluto stern and Proserpine;

Will not the miserable life I lead
  Move thee to pity—soften thy hard heart,
And cause my humble supplication speed?
If he who loses friend or worldly pelf
  Raises unchid his voice beneath the smart,
Oh what his claim, whose loss has been—himself!

But the reputation of Garcilaso rests chiefly on his pastoral poems, in which he has been imitated, but seldom if ever equalled by subsequent writers. The first of his eclogues, written at Naples, where he seems to have felt the inspiration of Virgil and Sanazzar, is by far the most beautiful, and has ever been considered as a masterpiece. The whole composition has the metrical form of an Italian canzone, and the plan is exceedingly simple. The author describes, with all the simplicity characteristic of genuine pastoral poetry, the meeting of two shepherds, Salicio and Nemoroso, who alternately pour forth their complaints—the one mourning the infidelity, and the other the death, of his mistress. In the strains of the former passion appears raised to the highest pitch, and then lost in an affecting self-sacrifice. In those of the latter there is even greater tenderness. In retracing his recollections, the mourner draws a series of melancholy pictures which have an indescribable charm. The beauty of the poem rises with the description of the beauty of the departed shepherdess. But the finest passage, and that which is considered to be unequalled either in ancient or modern poetry, is that in which Nemoroso relates how he carries in his bosom a lock of his Eliza's hair, with which he never parts for a moment—how, when alone, he spreads it out, wets it with his tears, dries it with his sighs, and then examines and counts every single hair. The poem, as a whole, is evidently the genuine effusion of the author's soul; and the glow of enthusiastic feeling, the happy choice of expression, and the harmony of versification to be found in almost every line of these songs of sorrow, cannot fail to gratify the admirers of elegiac poetry. There is also a purity of pastoral feeling, which appears the more remarkable, when we remember that the poet was a warrior, destined to perish in battle at no distant period.

The following are a few stanzas from this celebrated eclogue :—

Salicio. Through thee the silence of the shaded glen,
Through thee the horror of the lonely mountain
Pleased me no less than the resort of men ;
The breeze, the summer wood, and lucid fountain,
The purple rose, white lily of the lake,
Were sweet for thy sweet sake ;
For thee the fragrant primrose, gemm'd with dew,
Was sought when first it blew.
Oh how completely was I by all this
Myself deceiving ! oh the different part
That thou wert acting, covering with a kiss
Of seeming love the traitor in thy heart !
This my severe misfortune long ago
Did the soothsaying raven, sailing by
On the black storm with hoarse sinister cry,
Clearly presage. In gentleness of wo,
Flow forth, my tears—'tis meet that ye should flow !

How oft, when slumbering in the forest brown
(Deeming it fancy's mystical deceit),
Have I beheld my fate in dreams foreshown !
One day methought that from the noontide heat
I drove my flocks to drink of Tagus' flood,
And, under curtain of its bordering wood,
Take my cool siesta ; but arrived, the stream,
I know not by what magic, changed its track,
And in new channels, by an unused way,
Rolled its warpt waters back :
Whilst I, scorched, melting with the heat extreme,
Went ever following in their flight astray
The wizard waves. In gentleness of wo,
Flow forth, my tears—'tis meet that ye should flow !

* * * * *

But though thou wilt not come for my sad sake,
Leave not the landscape thou hast held so dear ;
Thou may'st come freely now without the fear
Of meeting me, for though my heart should break,
Where late forsaken, I will now forsake.
Come then, if this alone detains thee, here
Are meadows full of verdure, myrtles, bays,
Woodlands, and lawns, and running waters clear,
Beloved in other days,
To which, bedewed with many a bitter tear,
I sing my last of lays.
These scenes, perhaps, when I am far removed,
At ease thou wilt frequent
With him who rifled me of all I loved.
Enough ! my strength is spent ;
And leaving thee in his desired embrace,
It is not much to leave him this sweet place.

* * * * *

Nemoroso. As with the setting sun the shades extend,
And when its circle sinks, that dark obscure
Rises to shroud the world, on which attend
The images that set our hair on end,
Silence and shapes mysterious as the grave
'Till the broad sun sheds once more from the wave
His glorious lustre beautiful and pure ;
Such shapes were in the night, and such ill gloom
At thy departure ; still tormenting fear
Haunts, and must haunt me, until death shall doom
The so much wished for sun to reappear
Of thine angelic face, my soul to cheer,
Resurgent from the tomb.

* * * * *

Poor lost Eliza ! Of thy locks of gold
One treasured ringlet in white silk I keep
For ever at my heart, and when unrolled,
Fresh grief and pity o'er my spirit creep,
And my insatiate eyes, for hours untold,
O'er the dear pledge will like an infant weep ;
With sighs more warm than fire, anon I dry
The tears from off it ; number, one by one,
The radiant hairs, and with a love-knot tie ;
Mine eyes, this duty done,
Give over weeping, and with slight relief
I taste a short forgetfulness of grief.

WIFFEN.

The second eclogue contains a strange mixture of metres and styles : tercets are interchanged with rhymeless iambics, and the simple dialogue is suddenly abandoned for the dramatic. In the third, the genuine character of the pastoral is resumed, and the lyric dialogue in octaves harmonizes pleasingly with its tender description of amatory sorrow. But both are considered inferior to the first eclogue.

Garcilaso made essays in other kinds of poetry, but with less success. One of the most interesting is an elegy which was written at the foot of Mount Ætna, and addressed to Boscan. The mythological recollections excited in the poet by that classic ground, his mournful descriptions of the miseries of war, and his tender anxieties for a beloved object in his native land, diffuse a considerable charm over this elegant poem, which is, besides, fraught with comparisons and images at once novel and truthful.

The poems of Garcilaso, when collected, form only one small volume ; but these have secured him an immortal reputation, and obtained for him the highest rank among the lyric and pastoral poets of his country.

GARD, a department in the south of France, consisting of part of the old province of Languedoc, and bounded N. by the departments of Lozère and Ardèche, E. by the Rhone, which separates it from Vaucluse and Bouches-du-Rhône, S. by Hérault and the Mediterranean, and W. by Aveyron. It lies between 43. 27. and 44. 27. N. Lat., and between 3. 17. and 4. 50. E. Long., being about 75 miles in length from N. to S. and about 70 in breadth from E. to W. Area, 2308 square miles. The mountain range of the Cévennes skirts the department on the N.W., and hence the land gradually declines to the Rhone and Mediterranean. The southern portion, which extends to the sea, and was probably at one time covered by it, is a low plain with numerous lakes and marshes. Besides the Rhone, which bounds it on the E., and the Ardèche, the lower portion of which forms part of its boundary on the N., the principal rivers are the Cèze, Gard, Vidourle, and Hérault. The most northern of these is the Cèze, which rises in the Cévennes, and after a course of about 50 miles in an E.S.E. direction, falls into the Rhone below Bagnols. The Gard, or Gardon, also an affluent of the Rhone, and rising in the Cévennes from several sources, traverses the centre of the department, and has a course of about 60 miles in length. In the early part of its course it flows through a succession of deep mountain gorges; and from the melting of the snows on the Cévennes is subject to inundations, which often cause great damage. Its waters not unfrequently rise 18 or 20 feet in a few hours, and its bed is sometimes increased in width to nearly a mile. The Vidourle flows in a S.S.E. direction from its source near La Vigan, and falls into the shore-lake of Mauguio after a course of about 50 miles. Below Sommières it forms the western boundary of the department. The Hérault has its source and part of its course in this department. The Canal de Beaucaire extends from the Rhone at the town of that name to Aigues Mortes, which communicates with the Mediterranean by means of the *Grand-Roubine* canal. Gard is traversed by railways from Nîmes to Alais, from Nîmes to Beaucaire and thence to Marseilles, and from Nîmes to Cette, through Montpellier. This department is rich in minerals, which constitute one of the chief sources of its wealth, though the mining is carried on in an unskilful manner. Iron, coal, and argentiferous lead mines are extensively worked; and manganese, zinc, antimony, &c., are found. Great quantities of salt are obtained from the salt marshes along the coast. The gypsum and other quarries employ a considerable number of workmen. The manufactures of this department are extensive and varied. The chief of these are silk, cotton, and woollen fabrics, hats, gloves, paper, leather, earthenware, and glass. Agriculture is in a rather backward state, and the land, though generally fertile, does not produce corn sufficient for the wants of the inhabitants. The chief grain crops are wheat, oats, rye, and barley. Lentils, pease, and potatoes are grown; and immense quantities of excellent chesnuts are produced on the slopes of the Cévennes. The vine is extensively cultivated, and yields excellent red and white wines. The olive, mulberry, fig, pomegranate, and other fruit-trees are abundant. Gard contains 4 arrondissements, 38 cantons, 347 communes, and 408,163 inhabitants, as follows:—

	Cantons.	Communes.	Pop. 1851.
Nîmes	11	73	148,564
Alais	9	97	102,339
Uzes	8	98	90,011
Le Vigan	10	79	67,249
	38	347	408,163

The chief town is Nîmes, having (1851) 49,480 inhabitants.

GARDA, Lago di, the ancient *Benacus*, the largest of the Italian lakes, is in Austrian Italy, inclosed by the delegations of Mantua, Brescia, and Verona, and the circle of Roveredo in the Tyrol. It is about 35 miles in length from N. to S., and the southern portion, where widest, is 13 miles across, but it narrows towards the N., where its breadth is not more than 3 or 4 miles. At its northern extremity it receives the Sarco and numerous smaller streams; and its surplus waters are discharged by the Mincio into the Po. It is inclosed by Alpine ridges, except towards the S., where it is bounded by the great plain of Lombardy, and where the peninsula of Sirmio projects into its waters. The elevation of its surface is about 320 feet above the sea, and this is increased by 4 or 5 feet in the beginning of summer from the melting of the Alpine snows. Its greatest depth is 950 feet. Its waters are of a dark-blue colour, are subject to violent storms, and abound in fish. Near its E. shore Napoleon defeated the Austrians under Wurmser on 5th July 1796. Garda, the village from which the lake takes its name, stands on its eastern shore, and was anciently a port of some importance.

GARDANT, or Guardant, in *Heraldry*, a term applied to any beast full-faced, or looking towards the observer.

GARDELEGEN, a town of Prussian Saxony, on the right bank of the Milde, 30 miles N.N.W. of Magdeburg. Pop. (1849) 5857, chiefly engaged in the linen, woollen, and cotton manufactures.

GARDENING. See Horticulture, and Landscape-Gardening.

GARDINER, a town in the State of Maine, N. America, on the Kennebec river, 12 miles S. by E. of Augusta. It has numerous saw-mills, and contains 6486 inhabitants.

GARDINER, Colonel James, a Scottish soldier, remarkable alike for valour and piety, was born at Carriden in Linlithgowshire, Jan. 10, 1687. At the age of fourteen he entered a Scottish regiment in the Dutch service, and was afterwards present at the battle of Ramillies, where he was wounded. While in garrison during the intervals of his campaigns, he had distinguished himself by the recklessness with which he plunged into all the dissipation and excess incident to a military career. In 1719, however, a wonderful change came over him; and he was henceforth as remarkable for piety and Christian worth as he had formerly been for qualities the very opposite of these. The beautiful story of Colonel Gardiner's conversion, and the seemingly supernatural circumstances attending it, have been carefully detailed by his biographer, Dr Doddridge. He fell at the battle of Prestonpans in 1745. The circumstances of his death are described in *Waverley* with all the minuteness of historical detail, set off by the legitimate embellishment of romance.

Gardiner, *Stephen*, bishop of Winchester, and lord chancellor of England, was born at Bury St Edmunds in 1483. He is believed, on good grounds, to have been the illegitimate son of Dr Woodville, bishop of Salisbury, brother of Elizabeth Woodville, wife of Edward IV. After the usual preliminary studies, he was entered of Trinity Hall, Cambridge, where he distinguished himself as much by his knowledge of canon and civil law as by his classical attainments. In course of time he became himself Master of Trinity Hall, and made the acquaintance of Cardinal Wolsey, who introduced him to Henry VIII. Without much difficulty he gained the good-will of that monarch, who sent him in 1527 to Italy to gain the pope's consent to the divorce of Catherine of Arragon. In this mission he was not successful, but he showed such zeal and skill, that on returning home he was entrusted with the conduct of the case. He was likewise made secretary of state, and in 1531 was promoted to the bishopric of Winchester. In these high offices he distinguished himself by his constant and inflexible opposition to everything that smacked of change or progress, especially in matters of religion. Cranmer and the reformers in especial were made to feel the full weight of his hostility; and the opportune downfall of Cromwell removed a serious obstacle from the path of Gardiner's ambition. He was soon able again to testify his good-will to his royal benefactor by furthering the divorce of Anne of Clèves; but his spirit of intrigue seems to have shaken the confidence of the king, whose leanings were at this time beginning to pronounce in favour of Cranmer and the Protestants. It was not long before an opportunity occurred for Henry to show his real sympathies. Gardiner, as the representative of the Catholic party, tried to fix upon Cranmer the charge of heresy, but the attempt was defeated by the king himself, who secured the acquittal of the accused. The failure of this design did not much affect Gardiner's standing, but he damaged himself and his cause seriously by a scheme for the impeachment of Catherine Parr, which that lady had the good fortune to discover, and the skill to counterwork. On the accession of Edward VI. Gardiner experienced a serious reverse of fortune. Failing to comply with the demands of the now dominant Protestant party, he was thrown into the Tower, and kept there in close confinement till the premature death of the young king and the accession of his sister Mary completely changed the aspect of affairs. He was immediately set free, made lord chancellor, reinstated in his lost bishopric, and entrusted with the conduct of the most important affairs, both of the nation and of the queen's household. The atrocities that were perpetrated during the short but bloody reign of the new sovereign, if not directly chargeable against him, were certainly aggravated by having his sanction and countenance. Had he willed he might have prevented them, as there was no subject of the realm whose power and influence were comparable to his. He died November 12, 1555, and was buried with a more than royal magnificence.

Gardiner was a man of great practical ability. His ambition was as great as that of his quondam master Wolsey; and the height of power which he reached was inferior only to that attained by the great cardinal. In forwarding his ambitious views he made no scruple of sacrificing any thing or person that stood in the way; but as soon as he found his position secure, he was careful to advance the interests of the party on whose shoulders he had risen to power. His knowledge of men, and his tact in dealing with them, were far more remarkable than his knowledge of divinity, which, however, was far from commonplace. His cunning, that treacherous quality which formed so prominent a feature in his character, was sometimes so ill concealed as to injure rather than promote his views. Such a mind as his was constitutionally vindictive; and if he did not actually take pleasure in the sight of human suffering, he proved at least by his conduct that he did not object to the use of torture as a means for furthering the interests of the Roman Catholic Church. It is said that on his deathbed the retrospect of his life and conduct filled him with horror, and that he often repeated the words, *Erravi cum Petro, sed non flevi cum Petro,* I have sinned with Peter, but I have not wept with Peter. His principal works are—*De Vera et Falsa Obedientia,* 1534; *Palinodia dicti libri; A Necessary Doctrine of a Christian Man, set forth by the King's Majestie of England,* 1543; *An Explanation and Assertion of the true Catholic Faith, touching the most blessed Sacrament of the Altar,* 1551; *Confutatio Cavillationum quibus Sacrosanctum Eucharistiæ Sacramentum ab impiis Capernaitis impeti solet,* 1551.

GARNET, a beautiful gem of a rich red colour, passing from columbine red to cherry and brown red. Another species is the common garnet, the colour of which is of various shades of brown and green. See MINERALOGY.

GARNET, a tackle fixed to the mainstay of a ship, for hoisting cargo.

GAROFALO, BENVENUTO, whose family name was TISIO, a painter of very considerable merit, was born at Garofalo near Ferrara in 1481. After studying at his native city, at Cremona, and afterwards at Mantua, under the leading artists of these cities, he betook himself to Rome where Raphael was then at the height of his glory. The works of that great master, as was natural, affected his style very materially for the rest of his life. His works in his later manner placed him among the first painters of his day, and even now command large prices among connoisseurs. Vasari cites as his masterpieces, a "Massacre of the Innocents," a "Resurrection of Lazarus," and a "Capture of Christ." The same critic also mentions a "Martyrdom of St Peter," which he describes as nowise inferior to the famous painting by Titian on the same subject. Garofalo died in 1559.

GARONNE, the ancient *Garumna,* an important river of France, which rises in the Spanish Pyrenees, passes in succession through the departments of Haute Garonne, Tarn-et-Garonne, Lot-et-Garonne, and Gironde, and falls into the Bay of Biscay by the estuary of the Gironde after a course of about 300 miles. It has its source in the *Vallée d'Aran,* and enters France near the Pont du Roi in Haute Garonne. Hence it flows N.W. to its junction with the Neste, then N.E. to Toulouse, and afterwards in a N.W. direction to its mouth. It is navigable to Cazeres above Toulouse, and at Toulouse it is connected by the Canal du Midi with the Rhone and the Mediterranean. Its chief affluents on the right are the Salat, Ariège, Tarn, Lot, Dropt, and Dordogne; on the left, the Neste, Louge, Save, Gimoné, Gers, Baïse, and Ciron. At Bec d'Ambès, where it receives the Dordogne, it takes the name of Gironde. The Gironde presents an almost uninterrupted succession of islands and banks, which divide it into two nearly equal branches and render the navigation somewhat difficult. The valley of the Garonne is noted for its beauty and fertility.

GARONNE, *Haute,* one of the frontier departments in the south of France, bounded on the N. by the department of Tarn-et-Garonne, E. by those of Tarn, Aude, and Ariège, S. by the Pyrenees which separate it from Spain, and W. by the departments of Hautes Pyrénées and Gers. It is about 88 miles in length by 25 in average breadth; lying between 42. 40. and 43. 55. N. Lat., and between 0. 27. and 2. 3. E. Long. Area, 618,558 hectares, or 2388 English square miles. The northern portion of this department is covered by hills of moderate elevation, interspersed by broad and fertile valleys and plains. Towards the south the land gradually rises to the Pyrenees, some of the peaks of which here attain the height of upwards of 10,000 feet, while Mount Maladetta is 11,168 feet above the level of the sea. The scenery here is of the most wildly picturesque description. The mountains raising their lofty summits into the region of perpetual snow, the immense precipices, frightful chasms, and the numerous torrents and waterfalls, render this district, for savage grandeur, almost unrivalled. The lower slopes of the mountains are covered with thick forests of oak, fir, pine, &c., or are occupied as sheep walks and pasture grounds. The principal river of this department is the Garonne, from which it takes its name. The others, the principal of which are the Neste, Salat, Lers, Louge, Touque, Save, Ariège, and Tarn, are either directly or indirectly feeders of the Garonne. The navigable rivers are the Garonne, Tarn, Ariège, and Salat. The Canal du Midi traverses this department for 32 miles. The climate, except in the elevated region of the south, is temperate. The prevailing wind is the west; the south wind almost always brings rain. The mineral wealth of this department is considerable, and its mines, particularly of iron, are numerous. Copper, lead, antimony, bismuth, zinc, and coal are among its other mineral productions, and its marble quarries are extensively worked. Mineral springs are found in various places. In some of the mountain valleys, particularly in that of Luchon, cretinism is common. The arable land, which comprises more than a half of the department, is well adapted for the cultivation of wheat, maize, and other grain crops; and agriculture is in an advanced state. The produce of corn is generally nearly double what is required for home consumption. The neighbourhood of Toulouse is one of the most fertile portions of France, as well in corn as in pasture for cattle. Much fruit is produced, and vineyards are extensive, yielding wine of a medium quality, most of which is consumed at home or converted into brandy. The mountains and valleys afford excellent pasturage for cattle, which are numerous. Near Toulouse a fine breed of horses was formerly raised for the dragoon service, but it has been suffered to degenerate. The mountains abound with wood, well adapted for ship-building. The manufactures are various but not extensive, and include iron and copper utensils, earthenware, woollen, cotton, and linen goods, leather, hats, watches, mathematical instruments, &c. Haute Garonne is divided into 4 arrondissements as follows:

	Cantons.	Communes.	Pop. in 1851.
Toulouse	12	133	176,487
Villefranche	6	97	65,039
Muret	10	126	92,988
Saint-Gaudens	11	234	147,096
	39	590	481,610

The capital, Toulouse, contains 85,554 inhabitants.

GARRICK, **David**, the greatest actor of his age, and the most successful of theatrical managers, was descended from a French Protestant family (Garrique), that had settled in England on the revocation of the edict of Nantes. The father of David, Captain Peter Garrick, was on a recruiting expedition when his celebrated son was born at Hereford, and baptized there February 28, 1716-17. The captain usually resided at Lichfield on half pay, but in order to benefit his family he accepted an offer to proceed on service to Gibraltar in place of a brother officer who was desirous of returning to England. This kept him many years absent from his family, and the letters written to him by "little Davy," acquainting him with the doings at Lichfield, are highly interesting memorials of the future Roscius.[1] In his nineteenth year, after receiving a good education at the grammar-school of Lichfield, David was sent to the establishment at Edial, opened in June or July 1736 by that greatest of Lichfield men, Samuel Johnson. The Edial seminary was shut in about six months, and master and pupil, Johnson and Garrick, proceeded to London, one to commence the study of the law, and the other to try his tragedy of *Irene*. They left Lichfield on the 2d of March 1736-7. Seven days afterwards Garrick was entered of Lincoln's Inn, but he resided for some time with the Rev. Mr Colson, a distinguished teacher at Rochester. His father, who had returned from Gibraltar, died about a month after David's arrival in London, and it is worthy of note, that in his will, dated 1st January 1736-7, while he left liberal legacies to his other children, the youngest is only remembered by this bequest: "Item, to my son David, one shilling."[2] Fortunately a rich uncle, a wine merchant at Lisbon, in his will left David a sum of L.1000; and he entered into partnership with his brother as wine merchants in London and Lichfield. The concern was not prosperous, and before the end of 1741 David had spent nearly half of his thousand pounds. His passion for the stage completely engrossed him; and being acquainted with Giffard, manager of the theatre at Goodman's Fields, he accompanied that gentleman, with a party of his players, to Ipswich, where Garrick made his first essay as an actor under the name of Lyddal. His success on the provincial boards determined his future career. On the 19th of October 1741 he made his appearance at Goodman's Fields in the character of Richard III., and gained the most enthusiastic applause. His staid and sedate brother, and his sisters at Lichfield, were scandalized at this derogation from the provincial dignity of the family; and Garrick, greatly distressed at the shock they had received by the intelligence (which however he expected), hastened to give up his interest in the wine company. Each night added to his popularity on the stage. He was received by the best company in town. Glover ("Leonidas") attended every performance; Lyttelton, Pitt, and several other members of parliament, had shown him the greatest civility. Before next spring he had supped with "the great Mr Murray, counsellor," and hoped to do so with Mr Pope through Murray's introduction, while he was dining with Halifax, Sandwich, and Chesterfield. "There are a dozen dukes of a night at Goodman's Fields," writes Horace Walpole; and Garrick's farce of the *Lying Valet* being at this time brought out with success, the honours of dramatic author were added to those of the stage. His fortune was made.

Having very advantageous terms offered him for performing in Dublin during part of the summer, he went over to that city, where he found the same homage paid to his merit which he had received from his own countrymen. To the service of the latter, however, he esteemed himself more immediately bound; and therefore, in the ensuing winter, he engaged himself to Fleetwood, manager of Drury Lane. In this theatre he continued till 1745, when he again went over to Ireland, and continued there the whole season, as joint-manager with Sheridan, in the direction and profits of the theatre-royal in Smock Alley. From Dublin he returned to England, and was engaged for the season of 1746 with Rich at Covent Garden. This was his last performance as a hired actor; for in the close of that season Fleetwood's patent for the management of Drury Lane expired, and that gentleman having no inclination further to pursue a design by which, from his want of acquaintance with the proper conduct of it or some other cause, he had considerably impaired his fortune, Garrick, in conjunction with Lacy, purchased the property of the theatre, together with the renovation of the patent, and in the winter of 1747 opened it with the best actors, and especially with the famous prologue written by his old preceptor Johnson, who, though somewhat splenetic, if not envious, at Garrick's sudden rise, was glad to see

> " ——— the reign commence
> Of rescued nature and reviving sense."

The naturalness of Garrick's acting was its great charm. Booth, Quin, and the old tragedians were remarkable for a style of stately declamation, sonorous and often graceful and impressive, but wanting the versatility and rapid changes of passion that, when exhibited by Garrick, at once captivated the audience. "It seemed," said old Richard Cumberland, "as if a whole century had been stepped over in the passage of a single scene; old things were done away, and a new order at once brought forward, bright and luminous, and clearly destined to dispel the barbarisms of a tasteless age, too long superstitiously devoted to the illusions of imposing declamation." In comedy Garrick also excelled, and the variety of his acting was justly considered one of his peculiar excellences. As a manager, though he committed some grievous blunders, his career was beneficial to the stage. He purified it of much of its grossness, and introduced a correctness of costume and decoration unknown before. In 1749 Garrick was married to Mademoiselle Violette, a German lady, who had attracted the admiration of the court of Vienna as a dancer, and was patronized in England by the Countess of Burlington. The union was a happy one, and the lady survived, living in great respect, until 1822. Having sold the moiety of his theatre for L.37,000, Garrick took leave of the stage in 1776, but only enjoyed his opulent and well-earned repose for a period of less than three years, dying on the 20th of January 1779. Johnson, whose various and not always consistent criticisms on Garrick, are scattered through the pages of Boswell, spoke warmly of the elegance and sprightliness of his friend's conversation, as well as of his liberality and kindness of heart; and his death, which came upon him unexpectedly, "eclipsed," Johnson said, "the gaiety of nations, and impoverished the public stock of harmless pleasure." But the most accurate and discriminating character of Garrick, slightly tinged with satire, is that drawn by Goldsmith in his poem of *Retaliation*. As a literary man Garrick was happy in his epigrams and slight occasional poems. He had the good taste to recognise, and the spirit to make public his recognition of, the excellence of Gray's Odes at a time when they were either ridiculed or neglected. His dramatic pieces (the *Lying Valet*, *Lethe*, the *Guardian*, *Miss in her Teens*, *Irish Widow*, &c.), and his alterations and adaptation of old plays, evinced his knowledge of stage effect and his appreciation of lively dialogue and action, but he cannot be said to have added one new or original character to the drama. His correspondence, in two volumes quarto, and the notices of him in the Memoirs of Hannah More, Madame D'Arblay, and above all, in Boswell's Life of Johnson, bear testimony to his general worth and to his many fascinating qualities as a friend and companion. (R. C—S.)

---

[1] Forster's *Life of Goldsmith*, 2d edition, 1854.

[2] Cunningham's edition of *Johnson's Lives*. Garrick's early life may have been wild, as Mr Cunningham assumes, but we hear nothing of it while he was with Johnson at Edial; and in Gilbert Walmsley's letter to Colson, Garrick is mentioned as a very sensible young man, and a good scholar, whom the captain, his father, hoped to send to the temple and educate for the bar. Yet the captain's will was made about this very time. The specification of the "shilling" seems undoubtedly to imply marked displeasure; but David at this period received a legacy of L.1000 left him by his uncle at Lisbon, while his brother and sisters received only L.500 each. See Davies's *Life of Garrick*, in which work, however, there is some inaccuracy and confusion as to dates.

GARRISON (Fr. *garnison*, from the low Lat. *garnisio*, ammunition, military stores), a body of troops stationed in a fort or fortified town, either to defend the place against an enemy, to keep the inhabitants in subjection, or merely to be subsisted. By military writers the term is applied indifferently to a fortress, to the guard of a citadel or fortified place. and to the soldiers quartered in a town.

GARROTE, the name given in Spain to a mode of capital punishment by strangulation. The criminal is seated on a stool with his back to a stake, and his neck is encircled with an iron collar, which the executioner suddenly forces close by means of a screw, so as to cause instantaneous death.

GARROVILLAS, a secular town of Spain, in the province of Estremadura. It contains 6000 inhabitants, and is situated in a district studded with small elevations, of which the highest is the Santa Cruz de Brozas. It is supplied with excellent water, though sometimes not in abundance, and stands about two miles from the Tagus. Woollens and linens are manufactured here in considerable quantities.

GARROW and COSSYAH HILLS, a mountainous district of Hindustan, on the N.E. frontier of Bengal, between the 25th and 26th degrees of north latitude. Its boundaries are Goalpara and Camroop on the north, Jyntea on the east, Sylhet on the south, and Mymensing on the west. The area of the whole tract is estimated at 4347 square miles, of which the Garrows contain one-half, the other moiety being included within the Cossyah Hills. The population, which amounts to 65,205, is composed of the subjects of various native chiefs, who, though taken under British protection, are exempted from the payment of tribute. The character of the country is wild, as is also that of the people; but the liberal policy of the protecting government, and the interposition of its power only when rendered indispensable by the refractory chiefs, have succeeded in maintaining tranquillity. The people are of a stout make, vigorous and athletic, but ill-looking. They are not so dark as those in Bengal. They go nearly naked; and, although calling themselves Hindus, eat all kinds of food, and drink spirituous liquors. They worship Mahadeva; and at Banjam, a pass in the hills, they worship the sun and moon. They are poor and barbarous in their habits. Their houses are of the rudest description, being raised on piles three or four feet from the ground. The houses of the better classes are more neatly executed. They are said to be cheerful in their dispositions, and mild in their manners. At the foot of the Garrow Hills reside a tribe of people called Hajins, who are more like the Hindus, and who will not kill a cow.

GARSTANG, a small market-town of Lancashire, on the right bank of the Wyre, and on the Preston and Lancaster Railway, 11 miles S. of Lancaster. Pop. (1851) 839.

GARTER, ORDER OF THE, one of the most ancient and illustrious of the military orders of knighthood, was instituted by Edward III. of England, and dates from about the year 1350, though some writers refer its institution to 1344. Its origin is variously related. The common account is, that the Countess of Salisbury happened at a ball to drop her garter, and that the king took it up and presented it to her, at the same time exclaiming, *Honi soit qui mal y pense*, in reference to the smiles which he observed the action had excited among some of the bystanders; adding, "that shortly they should see that garter advanced to so high an honour and renown as to account themselves happy to wear it." In the opinion of some authorities, however, the motto of the order has reference to Edward's claim to the kingdom of France, and means that he retorted shame and defiance upon those who should dare to think amiss of the just enterprise he had undertaken for the recovery of his lawful right to that crown; and that the bravery of those knights whom he had elected into this order would enable him to maintain the quarrel against those who thought ill of it. Camden, Fern, and others, suppose it to have been instituted on occasion of the victory obtained by the Black Prince over the French at Cressy. That prince, say some historians, ordered his garter to be displayed as a signal of battle; and in commemoration thereof he made a garter the principal ornament of the order. In Rastel's *Chronicle* it is stated that this order was devised by Richard I. at the siege of Acre, when he is said to have caused twenty-six knights to wear thongs of blue leather about their legs, and that it was perfected in the 19th year of Edward III.

The number of knights companions was originally twenty-six, including the sovereign, who is chief of the order; but in 1786 a statute was passed to the effect that this number should be irrespective of princes of the royal family, and illustrious foreigners on whom the honour might be conferred. Their total number at present (1855) is thirty-eight. This order holds the highest rank among the British orders of knighthood. Its officers are a prelate, chancellor, registrar, king-at-arms, and usher of the black rod, besides others of inferior rank. At their head is the prelate, who is always the Bishop of Winchester; next is the chancellor, who, till 1837, was the Bishop of Salisbury, but is now the Bishop of Oxford, in consequence of Berkshire, and of course Windsor, being transferred to that diocese. The Dean of Windsor is registrar *ex officio*. The fourth officer is garter and king-at-arms, which are two distinct offices united in one person. The garter carries the rod and sceptre at the feast of St George (the protector of the order) when the sovereign is present; he notifies the election of new knights, attends the solemnity of their installation, carries the garter to foreign princes and others, and he is the principal officer of the college of arms and chief of the heralds. (See KING-AT-ARMS.) All these officers, except the prelate, have fees and pensions. The chapter meet annually on St George's day (23d April) in St George's chapel, Windsor, where the installations take place, and the knights' banners are suspended. The habit and insignia are the garter, of blue velvet, and inscribed with the motto "Honi soit qui mal y pense," worn below the left knee; the mantle, of blue velvet; the hood and surcoat of crimson velvet; the hat of black velvet; the collar of gold; the george, or figure of St George, suspended from a broad dark blue riband; the star of silver. The Garter challenges pre-eminence over all the other parts of the dress, for from it the noble order received its denomination. It is the first part of the habit presented to foreign princes and absent knights, and that wherewith they and all other knights elect are first adorned. The mantle is the chief of the vestments made use of upon all solemn occasions. The length of the train of the mantle distinguishes the sovereign from the knights companions. To the collar of the mantle is fixed a pair of long strings, anciently woven with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robes, with knobs or buttons, and tassels at the end. The left shoulder of the mantle has from the institution been adorned with a large garter, with the device. Within this is the cross of the order, which was ordained to be worn at all times by Charles I. At length the star was introduced, which is a sort of cross irradiated with beams of silver. The collar is appointed to be composed of pieces of gold in fashion of garters, the ground enamelled blue, and the motto gold. When the knights wear not their robes, they are to have a silver star on the left side: and they commonly bear the picture of St George, enamelled on gold, and set with diamonds, suspended by a dark blue riband, crossing the body from the left shoulder.

The garter, at the time of election, is buckled upon the left leg by two of the senior companions, who receive it from the sovereign (to whom it has previously been presented upon a velvet cushion by the Garter king-at-arms), with the usual reverence, whilst the chancellor reads the admonition enjoined by the statutes. The garter being then buckled on, and the word of its signification pronounced, the knight-elect kneels before the sovereign, "who puts about his neck a dark blue riband, to which is appended, wrought in gold within the garter, the image of St George on horseback, with his sword drawn, encountering the dragon." In the mean time, the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ, St George, by whose imitation provoked, thou mayest so overpass both prosperous and adverse encounters, that having stoutly vanquished thy enemies both of body and soul, thou mayest not only receive the praise of this transient combat, but be crowned with the palm of eternal victory." Then the knight elected kisses the sovereign's hand, and returns thanks for the great honour done him; after which he rises up and salutes all the companions severally, who return their congratulations.

In the beginning of the present century it was estimated that eight emperors and twenty-eight foreign kings, besides numerous sovereign princes, had been enrolled as knights companions of the Order of the Garter. Ashmole has given a very elaborate account of this order. See also the splendid work of Sir H. Nicolas on the Orders of Knighthood.

Garter, principal King-at-Arms. See King-at-Arms.

Garter is also a term in heraldry, signifying the moiety or half of a bend.

GARTH, Sir Samuel, a well-known physician and poet of the Queen Anne and early Georgian period, was a native of Yorkshire. He studied at Peterhouse, Cambridge, joined the college of physicians in London, and became a fellow in 1692. He was the leading Whig physician, as Radcliffe was that of the Tories; and in 1714 he was knighted with Marlborough's sword by George I. His social and liberal spirit made him friends among all parties, and he also enjoyed considerable reputation as author of the *Dispensary*, a popular poem on a popular subject. This appeared in 1699, and went through seven editions in the author's lifetime, each edition being corrected and enlarged. On a copy at present (1855) in the possession of Mr Rogers, Pope made some corrections, which were adopted by Garth. The object of this poem was to ridicule the company of apothecaries and certain medical men who set themselves to thwart and oppose a benevolent edict issued by the college of physicians, that the poor should have advice gratis. The subject is treated in a ludicrous allegorical style, in the heroic couplet, which Pope afterwards carried to such perfection in his *Rape of the Lock* and other works. Garth also edited a translation of Ovid's *Metamorphoses*, supplying himself the fourteenth and part of the fifteenth book. This was published in 1717, and he died in 1719. In the brilliant society of that period, as a member of the *Kit Kat Club*, and the associate of Halifax, Addison, Congreve, Swift, and Pope, Garth appears to have been a favourite. He was unfixed in his religious opinions, but Pope says he was a good Christian *without knowing it*, and that he died a Papist. A more characteristic anecdote is related by Swift's friend Alderman Barber, who writes to the Dean, "You may remember Mr Garth said he was glad when he was dying, for he was weary of having his shoes pulled off and on!" The force of *pococurante* indifference could no further go. But there was little serious feeling among the wits of that age, save with Addison and Arbuthnot, and most of them affected a sort of Roman superiority to those terrors of death which have shaken so many stronger minds. (R. C—S.)

GARVE, Christian, a distinguished German miscellaneous writer, was born at Breslau in 1742. He lost his father at an early age, but was very carefully educated under the superintendence of his mother. He studied mathematics and philosophy under Baumgarten, at Frankfort-on-the-Oder; and thence he removed successively to Halle and Leipzig, where he enjoyed the friendship of Weisse, Gellert, and other *literati.* After Gellert's death in 1769, Garve was appointed to succeed him, and his lectures on logic and mathematics were universally approved. His delicate health, however, compelled him to resign his professorship; and he retired to his native city, where he continued to teach privately for the remainder of his life. He had long suffered under a complication of painful diseases, and after much severe suffering he died in 1798.

Garve first made a name for himself by his translation of Burke's essay *On the Sublime and Beautiful*, and other works, such as the *Ethics*, *Politics*, and *Rhetoric* of Aristotle. His translations from the Greek, however, though not without certain literary merits, want that first requisite of all translations—fidelity. He was more happy in his rendering of Cicero *De Officiis*, which he edited and annotated at the request of the great Fritz of Prussia, who had been struck with some of his philosophical essays, and had invited him to Charlottenburg, where he had entertained him with unusual courtesy. These *Philosophische Abhandlungen* of Garve's consist principally of essays on ethical subjects, or subjects of general import, such as *Patience*, the *Art of Thinking*, *Irresolution*, the *Existence of God*, and such like. They are all treated in a popular style, but, though popular, are far from commonplace. They often present a worn-out theme in a guise so fresh and pleasant as to have all the attractions of novelty.

GAS, a general name for all those elastic fluids that preserve their aëriform state at ordinary temperatures. See Chemistry.

GASKET, a cord or piece of plaited stuff by which a sail, when it is furled, is secured to the yard or boom.

Gasket also denotes yarn of flax or hemp saturated with tallow. It is used as packing for the stuffing-boxes of engines, to make tight the joints of iron pipes, &c.

GAS-LIGHT.

Importance of light.

Light, whether obtained from natural or artificial sources, is so necessary for the correct and successful execution of almost every operation of human industry, that whatever is calculated to simplify the means of procuring it, or to increase its intensity, cannot fail to be attended with the most beneficial consequences to civilized society. For every purpose to which it is applied, it must be admitted that the light of day, when it can be enjoyed freely and without interruption, is by far the most suitable; but in large and crowded cities, as well as in situations less favourable in point of climate, where the sun is sometimes shrouded for days together in dense and impenetrable clouds, it becomes expedient to compensate for the absence of his rays by artificial substitutes, which, however inferior in brilliancy and general usefulness, may nevertheless answer sufficiently well in those cases where a less ample supply of light is requisite.

Phosphorescent substances.

Some substances, denominated *phosphorescent*, have the property of absorbing the solar rays, on being exposed for a short time to their influence, and of emitting the light which they thus imbibe when they are afterwards placed in the dark; but the feeble and transient illumination which they shed. though sufficient to indicate their luminous condition, is totally unfit to afford such a supply of light as is necessary for conducting any of the operations of art, which require care and precision for their performance.

Substances from which artificial light is obtained.

There are, however, a variety of inflammable substances, both of animal and vegetable origin, which, during the process of combustion, give out light as well as heat; and hence, from the earliest periods of human society, it has been customary to burn substances of that description for the purpose of obtaining artificial light. These substances, which were generally of a fatty or oleaginous nature, are composed chiefly of carbon and hydrogen. When they are exposed to a certain high temperature, they are resolved into some of the compound gases which result from the union of these elements, particularly carburetted and bicarburetted hydrogen, or olefiant gas, both of which are highly inflammable, and yield, during their combustion, a fine white light. In order to facilitate the decomposition, and to carry on the combustion with due economy, a quantity of some fibrous substance, in the form of a wick, is connected with the oleaginous matter, for the purpose of causing it to burn slowly and effectually. Accordingly, if the flame be suddenly extinguished, the inflammable gas which is formed by the decomposition of the matter in immediate contact with the wick is observed to escape from it, and may be again set on fire by the application of a lighted taper.

When it is required to convey from place to place the light obtained from these substances, no arrangement is found to be more convenient for their decomposition than that which is effected by means of the wick; but if the light is to remain in a permanent position, it will frequently be more advantageous to resolve the oleaginous matter into gas, and then to transmit it, in that state, through pipes, to the various points where it is to be consumed.

Although the different substances which have been used from the earliest times for yielding artificial light have always been actually resolved into gas before they underwent the process of combustion, that fact was entirely unknown until pneumatic chemistry unfolded the properties of the aërial bodies, which perform so many important functions in the economy of nature, as well as in the processes of the arts. It was then discovered that hydrogen, one of the component parts of water, was a highly inflammable gas, capable of being produced under a great variety of circumstances: from vegetable matter decaying in stagnant water, forming what is called light carburetted hydrogen, a stream of which, when ignited, produces the natural phenomenon known as "ignis fatuus, or Will-o'-the-Wisp:" from coal, oils, and fatty substances, when, in combination with larger proportions of carbon, it forms gases of high illuminating powers. The use of gas for the purpose of illumination is therefore of recent date; but although late in its origin, the successive improvements which the invention has received, and continues to receive, from the joint labours of chemists and practical engineers, have tended greatly to simplify the processes for producing the gas, and for improving its quality and means of distribution.

Discovery of coal-gas.

In many parts of the world there are certain deposits of petroleum or naphtha which furnish gaseous matter; and this issuing from some fissure in the earth, becomes ignited by lightning or some other cause, and continues to burn for a long period. Such a flame is regarded by an ignorant people with superstitious reverence, and has been sufficient to found a religious sect of fire-worshippers. Deposits of coal, or of bituminous schist, sometimes furnish the gaseous matter for such flames. The practical Chinese, about thirty miles from Pekin, are said to make use of this gas in the boiling and evaporating of salt brine, and for lighting their streets and houses. "Burning fountains," as they are sometimes called, are not uncommon, and their origin is the same. In 1851, in boring for water on Chat Moss, on the line of railway between Manchester and Liverpool, a stream of gas suddenly issued up the bore, floated along the surface of the ground, and caught fire on the application of flame. A pipe was inserted into the bore, and a flame eight or nine feet long was thus produced.

In 1667, Mr Shirley describes in the Philosophical Transactions of the Royal Society a burning spring in the coal district of Wigan in Lancashire: he traced its origin to the underlying beds of coal. In 1726, Dr Hales, in his work on *Vegetable Statics* gives an experiment on the distillation of coal, by which it appears that 158 grains of Newcastle coal yielded 180 cubic inches of inflammable air. In 1733, Sir James Lowther sent to the Royal Society specimens of inflammable air from a coal-mine near Whitehaven. The gas was collected in bladders, and a number of experiments were tried on it.

It appears, however, that the Rev. John Clayton had performed some experiments on the distillation of coal some years previous to the publication of Dr Hales's book; but he did not publish an account of them until 1739, and this account consists of an extract from a letter written by Clayton to the Hon. Robert Boyle, who died in 1691, and was probably written some time before this year. It is inserted in the Transactions of the Royal Society for the year 1739; and is probably the earliest evidence of the possibility of extracting from coal, by means of heat, a permanently elastic fluid of an inflammable nature. We shall therefore give the account of the discovery in his own words: Having introduced a quantity of coal into a retort, and placed it over an open fire, he states that "at first there came over only phlegm, afterwards a black oil, and then likewise a spirit arose which I could noways condense; but it forced my lute, or broke my glasses. Once when it had forced my lute, coming close thereto in order to try to repair it, I observed that the spirit which issued out caught fire at the flame of the candle, and continued burning with violence as it issued out in a stream, which I blew out and lighted again alternately for several times. I then had a mind to try if I could save any of this spirit; in order to which I took a turbinated receiver, and putting a candle to the pipe of the receiver whilst the spirit arose, I observed that it catched flame, and continued burning at the end of the pipe, though you could not discern what fed the flame. I then blew it out and lighted it again several times; after which I fixed a bladder, squeezed and void of air, to the pipe of the receiver. The oil and phlegm descended into the receiver, but the spirit still ascending, blew up the bladder. I then filled a good many bladders therewith, and might have filled an inconceivable number more; for the spirit continued to rise for several hours, and filled the bladders almost as fast as a man could have blown them with his mouth; and yet the quantity of coals I distilled were inconsiderable.

"I kept this spirit in the bladders a considerable time, and endeavoured several ways to condense it, but in vain. And when I had a mind to divert strangers or friends, I have frequently taken one of these bladders, and pricking a hole therein with a pin, and compressing gently the bladder near the flame of a candle till it once took fire, it would then continue flaming till all the spirit was compressed out of the bladder; which was the more surprising, because no one could discern any difference in the appearance between these bladders and those which are filled with common air."[1]

Experiments of Mr Murdoch.

It is evident from this narrative, related with so much simplicity, that an accident which happened to Mr Clayton's apparatus was the means of leading to the discovery of coal-gas; but it does not appear that he or any other individual thought of applying the discovery to any practical purpose until the year 1792, when Mr Murdoch, who then resided at Redruth, in Cornwall, commenced a series of experiments upon the properties of the gases contained in different substances. In the course of his researches he found that the gas obtained by distillation from coal, peat, wood, and other inflammable substances, yielded a fine bright light during its combustion; and it occurred to him, that by confining it in proper vessels, and afterwards expelling it through pipes, it might be employed as a convenient and economical substitute for lamps and candles.

Progress of gas-lighting.

Mr Murdoch's attention to the subject having been interrupted for some time by his professional avocations, he resumed the consideration of it in 1797, when he exhibited publicly the results of his more matured plans for the preparation of coal-gas. The following year (being then connected with Messrs Boulton and Watt's engineering workshop), he constructed an apparatus at the Soho foundery for lighting that establishment, with suitable arrangements for the purification of the gas; and these experiments, Dr Henry states, "were continued with occasional interruptions until the epoch of the peace in 1802, when the illumination of the Soho manufactory afforded an opportunity of making a public display of the new lights; and they were made to constitute a principal feature in that exhibition."

In this brief sketch of the progress of gas-lighting, it may be noticed that the Lyceum theatre in London was lighted with gas in the course of the years 1803–4, under the direction of Mr Winsor, who is entitled to no small commendation for the warm interest which he took in drawing the public attention to the subject; and in 1804–5 Mr Murdoch had an opportunity of carrying his plans into effect on a still larger scale, by means of the apparatus erected under his superintendence in the extensive cotton mills of Messrs Philips and Son of Manchester.

When first used in France.

It has been alleged that gas-lights were used in France before they were known in this country; but as the earliest exhibition of these lights, on which the claim of priority of discovery is founded, took place at Paris in 1802, it is evident, from the foregoing statements, that the exhibition alluded to was ten years subsequent to the first experiments of Mr Murdoch on the subject.

Gas-works in London.

The practicability of lighting by means of coal-gas having been demonstrated by Mr Murdoch, a number of scientific men applied their talents to the further development of the art. Dr Henry, the celebrated chemist, lectured on the subject in 1804 and 1805, and furnished many hints for the improvement of the manufacture. Mr Clegg, an engineer in the employment of Boulton and Watt, was a worthy successor of Murdoch, and for many years was the most eminent gas-engineer of this country. A good deal of the machinery of the gas-house in its present form was contrived by Mr Clegg, and to him also we are indebted for the ingenious wet gas-meter. In 1813 Westminster bridge was first lighted with gas, and in the following year the streets of Westminster were thus lighted, and in 1816 gas became common in London. So rapid was the progress of this new mode of illumination, that in the course of a few years after it was first introduced, it was adopted by all the principal towns in the kingdom, for lighting streets as well as shops and public edifices. In private houses it found its way more slowly, partly from an apprehension, not entirely groundless, of the danger attending the use of it; and partly, from the annoyance which was experienced in many cases, through the careless and imperfect manner in which the service-pipes were at first fitted up. These inconveniences have been in a great measure, if not wholly, removed by a more enlarged knowledge of the management of gas; and at present there are few private houses in large towns which are not either partially or entirely lighted up by it. As the demand for gas increased, various improvements were from time to time introduced both in the mechanical arrangements, and in the chemical operations of the manufacture. The rapid increase in the population of the metropolis, and of all large towns, has naturally led to an increased consumption of gas, and the application of gas to the purposes of warming and cooking has also further increased the demand for it. Hence it has been not only necessary that new gas-works should be erected for the supply of new districts, but that the resources of old works should be enlarged. It is only a few years ago that a gas-holder, capable of storing 250,000 cubic feet of gas was regarded as of enormous size; at the present time, gas-holders are made of double that capacity, and we occasionally hear of them of the capacity of upwards of a million cubic feet. There is one such at Philadelphia; it is 140 feet in diameter and 70 feet in height. Nor will such dimensions as these be regarded as superfluous when it is stated that some of the large metropolitan works send out each from a million to a million and a half cubic feet of gas in one night in midwinter.[2] The Westminster gas-works alone are accustomed to supply as much as five millions cubic feet of gas in one night from their three stations.

---

[1] Mr Clayton also alludes to the discovery of the gas which he obtained from coal, in a letter to the Royal Society, dated May 12, 1688.

[2] The manufacture of gas has now become of such vast extent and importance, and so many persons are interested in it commercially, practically, and theoretically, that a journal devoted to its details has been found necessary. The *Journal of Gas-Lighting* is published twice a-month, and reports the progress of the art. It also publishes a share list of gas companies for the United Kingdom, which will give some idea of the extent of the manufacture. Many of the continental cities are also lighted with gas by English companies. A few years ago Mr Hume, in the House of Commons, moved for a return, which has been published under the following title:—"Return or statement from every gas company established by act of parliament in the United Kingdom, stating the several acts of parliament under which established, the rates per 1000 cubic feet at which each company or corporation have supplied gas in each of the three years since 1846 to 1849, and the average prices of the coals used by the company in each year for the same period; also stating the amount of fixed capital invested by each gas company, and the rate per cent. of dividend to the shareholders or proprietors on their shares in each year since that date (in continuation of Parliamentary Paper No. 734 of Session 1847)." It appears from this document that the fifteen

Of the Site and general Arrangement of the Apparatus for the Production and Purification of Coal-Gas.

Site and general arrangements.

In describing the site and general arrangements of a gas establishment, it is not easy to give directions respecting points which must be regulated in every case by circumstances of a local nature; but when a choice of ground is in our power, a spot ought to be selected having a central situation with regard to the buildings, streets, &c. which are to be supplied with light, and standing as nearly as possible on a medium level with them. When the manufactory is placed considerably below that level, the gas is apt to be propelled with too much velocity through the burners; and when above it, an opposite inconvenience is experienced, the gas being in that case necessarily subjected to an extra pressure, by which the chance of its escape through any imperfection of the pipes is proportionally increased. Of the two evils, therefore, the least objectionable is that in which the situation of a gas-work is below the mean level of the streets.

But besides the conditions favourable to an equable and uniform distribution of the gas at the different points to which it may be conducted, there are other considerations scarcely less important, which in selecting a proper site for the erection of the establishment ought not to be disregarded. Among these may be reckoned a regular supply of water for the various manipulations of the work; and facility of access for the delivery of coal and the removal of the coke, tar, and other products of the distillation. Railways are now so common that they are often as valuable to a gas-work as the vicinity of navigable water. In the Central Gas-consumer's works at Bow Common, which were laid out under the skilful scientific direction of Mr Croll, a branch railway is connected with the lines which supply the coal, and is actually continued into the retort-house, so that the coal waggons only arrive at their final destination at the mouths of the retorts which are to be fed. But in fixing the situation of an establishment which is professedly erected for the public benefit, the comfort or the interest of individuals ought not to be entirely overlooked; for although a gas-work may not prove, under proper management, a nuisance, it can never be considered to be any advantage to the neighbourhood in which it is placed.

Apparatus for the production and purification of gas.

The apparatus for the production and purification of coal gas consists, in the first place, of suitable vessels for decomposing by heat the coal from which the gas is to be procured; secondly, of a series of pipes for conveying off the gas, and conducting it into proper receptacles, where it may be separated from the grosser products, which tend to impair the brilliancy of the light; thirdly, of the condensing apparatus, for removing more effectually the tar and other condensible substances that come over with the gas; fourthly, of the purifying apparatus, for abstracting the sulphuretted hydrogen, carbonic acid, &c. by which the gas is contaminated, and which if allowed to remain, would be injurious to the gas-fittings, to the books and furniture of rooms, or to the health of the consumer; and, fifthly, of the gasometer or gas-holder, with its tank, into which the gas is finally received in a purified state.

Of the Retorts, or Vessels for decomposing the Coal.

The vessels employed for the decomposition of coal and other substances capable of yielding carburetted hydrogen, by their destructive distillation, are formed of cast iron, of clay, of brick, or of wrought iron, and are termed *retorts*. Various shapes have been adopted in the construction of these vessels; nor have their forms been more varied than the modes in which they have been disposed in the furnaces erected for their reception. In many instances they have been constructed of a cylindrical shape, varying in length and diameter. Those first employed were placed with their axis in a vertical direction, but experience soon showed that this position was extremely inconvenient, on account of the difficulty which it occasioned in removing the coke, and other residuary matters, after the coal had been carbonized. Attempts were made to remedy this inconvenience, by enlarging the size of the retort, and introducing the coal inclosed in a proper grating of iron, having the form of a cage. The increased dimensions of the retort, from which the principal advantage to be derived from this arrangement was expected, were found, however, to present great obstacles to the complete carbonization of the coal; for although the disengagement of gas during the first stages of the process was sufficiently copious, it diminished rapidly the longer the distillation was continued, in consequence of a crust of coke being formed next to the heated metal, which not only opposed the transmission of the heat to the internal mass of coal, but gradually prevented, by its accumulation, the extrication of the gas from the undecomposed portion of it.

Modes of heating the retorts.

The retorts were, therefore, next placed in a horizontal position, as being not only more favourable to the most economical distribution of the heat, but better adapted to the introduction of the coal, and the subsequent removal of the coke, after the carbonization was carried to a due extent. At first the heat was applied directly to the lower part of the retort, but it was soon observed that the high temperature to which it was necessary to expose it, for the perfect decomposition of the coal, proved destructive to it, and rendered it useless long before the upper part had sustained much injury. The next improvement was, accordingly, to interpose an arch of brickwork between it and the furnace, and to compensate for the diminished intensity of the heat by a more diffused distribution of it over the surface of the retort. This was effected by causing the flue of the furnace to return towards the mouth of the retort, and again conducting it in an opposite direction, till the heated air finally escaped into the chimney.

Form of retorts.

This arrangement continued for a long time in use, and seemed to admit of little improvement, unless with respect to the shape and dimensions of the retorts. The cylindrical form *a*, fig. 1, has the advantage of possessing great durability, but it is not so well fitted for rapid decomposition of the coal (on which depends much of the good qualities of the gas) as the elliptical shape *b*. Flat-bottomed, or D-shaped retorts, *d*, have also been long in use: the small London D is about 12 inches wide by 12½ inches deep, while the York D varies from 20 to 30 inches in width, and from 9 to 14 inches in height. Retorts are also made of a rectangular section, with the corners rounded and the roof arched. Elliptical retorts are varied into what are called *ear-shaped* or *kidney-shaped*, *c*, and it is not unusual to set retorts of different forms in the same bench, for the convenience of filling up the haunches of the arch which incloses them. The length of retorts formerly varied from 6 to 9 feet: they are now in some cases made 19½ feet in length

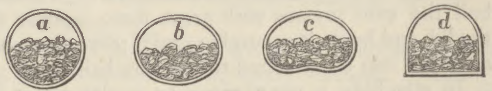

Fig. 1.

---

companies in London charged at the rate of 6s. per 1000 cubic feet of gas, with the exception of the City of London Company, which charged only 4s. with coals at 15s. 9d. per ton. The highest rate is 10s. per 1000 feet, charged at Inverness, with coals at 24s. 4d. per ton. Bury St Edmunds charged 8s. 4d., with coals at 10s. 6d. Birmingham has rates of 6s. and 3s. 4½d., with coals at 15s. per ton.

and 12½ inches in internal diameter, and are charged at both ends.

Iron retorts of from 6 to 9 feet in length carry a charge of from 120 to 200 lb. of coal, which is usually renewed every six hours. Instead of the old method of charging with the shovel, which occupied at least half an hour, and entailed a great loss of gas, the whole charge is now deposited in an iron scoop, with a cross handle at the end, and it is lifted by three men, pushed into the retort, turned over, and the whole charge deposited at once, a contrivance which does not occupy more than 30 or 40 seconds. Indeed it is not uncommon for a bench of 7 retorts to be emptied and recharged in the brief space of 20 minutes. When square-backed retorts are used, the backs are apt to wear much more quickly than any other part, in consequence of the fierce heat which plays upon them; it is therefore sometimes usual to throw in a few shovels-full of coal to the extreme end before depositing the charge with the scoop. This occupies more time in the charging, but it has the effect of preserving the backs. The objection does not apply to retorts with circular ends.

Every retort is furnished with a separate mouthpiece, usually of cast iron, with a socket *b*, fig. 2, for receiving the stand-pipe, and there is a moveable lid attached to the mouth, together with an ear-box cast on each side of the retort for receiving the ears which support the lid. Fig. 2 shows the mouthpiece attached to the retort *a*, and also the method of screwing the lid to the mouthpiece. The ears hold a cross-bar through which is passed a screw which presses on the lid, and secures it to the mouthpiece. That part of the lid which comes in contact with the edge of the mouthpiece has applied to it a lute of lime mortar and fire-clay, and when the lid is screwed up, a portion of this lute oozes out round the edges and forms a gas-tight joint.

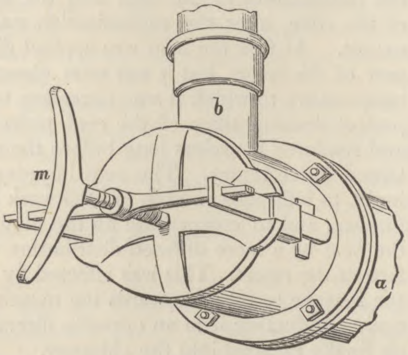

Fig. 2.

In some cases the screw is got rid of by a more expeditious contrivance, shown in figs. 4 and 5, in which the ears support an axis, which carries a lever formed at one end into a sort of cam, and bearing at the other end a ball of cast iron about 4 inches in diameter. On lowering this ball the cam presses with great force against the back of the lid, and holds it securely; and if more force be required, a weight can be attached to the iron ball.

In attaching a mouthpiece to a clay retort, the end is notched with grooves for the purpose of holding the binding cement more securely. The mouthpiece is attached by means of bolts with ⊤ heads let into the body of the retort. Iron cement is used, in which fire-clay takes the place of sulphur; this being spread over the joint, the mouthpiece is attached and screwed up.

Mode of setting retorts.

The temperature best suited for the production of gas from coal, being what the workmen term a *bright red*, was found to be very destructive to the retorts when they were exposed to the direct action of the fuel; and accordingly means were employed to protect them from the rapid oxidation which they suffered under these circumstances, by interposing between them and the furnace a partition of fire tiles or arched bricks, with side flues for the admission of the heated air.

With the view of occupying less room, and saving the expense of fuel, several retorts are sometimes set together in an oven of brickwork, and heated by a smaller number of furnaces than there are retorts. By this arrangement the fuel is certainly economized; but the plan is liable to the objection, that when any one of the retorts is worn out, those connected with it cannot be used till the faulty one is replaced; and though various expedients have been proposed for obviating that inconvenience, none of them can be said to have effectually answered the purpose. Figs. 4 and 5 represent an arrangement of the oven plan. A is the retort, *g* the furnace, *f f* the flues. Mr Croll's arrangement is represented in fig. 3.

Fuel for carbonization.

The fuel required for carbonizing a given quantity of coal may be stated to be, in general, from one-third to one-fourth of its weight for Newcastle coal. It is stated, that under Mr Croll's method of setting, the carbonization is carried on by the combustion of only 12 per cent. of fuel, or that 100 tons of coal are carbonized by 12 tons of coke.

Varieties of retorts.

Various attempts have been made to render the retorts more independent of the labourers. In Mr Brunton's retort, a hopper containing the charge of coal is attached to the mouthpiece. The charge is introduced by removing a slide, and a piston is then advanced for the purpose of pushing forward the coal, and ejecting the coke, the latter falling through a shoot at the further end of the retort, and thence into a cistern of water into which the lower end of the shoot dips. This retort is not of equal section throughout: it is 15 inches in diameter at the mouth, and 21 inches at the other end, the length being 4½ feet. The advantages of this arrangement, independently of the saving of labour, are said to be an increased production of gas, and a consequent diminution in the amount of tar, naphtha, and ammoniacal liquor, this diminution being stated at 50 per cent. less than the ordinary yield of those secondary products. Moreover, a good deal of bituminous vapour, and minutely divided carbon, which, under the usual arrangement, go to swell the increase of tar, become decomposed under the higher temperature of Mr Brunton's retorts by passing over the red-hot coke, and forming illuminating gas. Indeed, it is now generally admitted as an axiom in gas-making, that the most productive yield of gas is under a high temperature; for it is possible under low heats to distil off the volatile parts of the coal as bituminous vapour only, without any production of carburetted hydrogen gas. By exposing the coal in a thin layer to a very high heat, the distillation is effected most rapidly and most profitably. Mr Clegg describes a retort into which the coal is introduced by means of an endless web formed of iron plates, each 2 feet long, and 14 inches wide, and linked together by iron rods. The coal, broken small, is placed in a hopper, to which is attached a feeder with six radial projections. Each of the six partitions thus formed supplies sufficient coal to cover one plate of the web, with about 120 cubic inches of coal to the depth of ⅜ths of an inch. The hopper, which contains 24 hours' charge of coal, is luted after each charge. The endless web is moved by passing over drums, one revolution of which every 15 minutes conveys the web through the retort, and effects the distillation of the coal. The coal is carried on the upper surface of the web, and as the web turns over the second drum the coke is discharged by a pipe into a vessel below, and the empty portion of the web returns to the hopper, and passing over the surface of the first drum receives another charge. The charge is so regulated, that about 100 squares inches of heated surface in the retort is allowed for every pound of coal, which is said to yield 5·36 cubic feet of gas, or 12,000 cubic feet per ton of Wallsend coal. The charge for each retort is about 18 cwt. of coal for 24 hours, or about double the quantity under the old plan in retorts of similar dimensions. The coke is also said to be in much greater quantity. In the course of time the plates of the iron web become converted into steel, the value of which is sufficient for the purchase of a new web. Mr Lowe has also introduced an arrangement for increasing the yield of gas by making the products of a new change pass over the portion of the retort which is already at a red heat. For this purpose the *reciprocating retort*, as it is called, is made of thrice the usual length, and is charged at both ends; but the dip pipe at one end is made to enter to a greater depth into the tar of the hydraulic main than at the other end; so that supposing both the dip pipes to be open, the products of distillation will of course be discharged into the main by the shorter pipe, where there is less pressure to be overcome. This pipe, however, is furnished with a cup-valve, which can be closed at pleasure; and when so closed, the products of distillation must escape by the longer dip-pipe. When the charge has been half worked off in one-half of the retort, a fresh charge is introduced into the other half, and the products of distillation of the new charge are made to pass over the incandescent coal, or that which has been about three or four hours under distillation. This is readily effected by closing or opening the shorter dip-pipe, according to the end of the retort last charged. The principle of the reciprocating retort has been adopted at different works, with variations in the practical details.

Of late years clay retorts have been largely introduced into gas works, and they are said to be more durable, and to stand a higher temperature than iron retorts, the latter working best at a cherry-red heat, and the former at a white heat, which is more favourable to the increased production of gas than the lower temperature. It is stated, that where a clay retort has yielded a million and a half cubic feet of gas, an iron one has furnished only 800,000 cubic feet. Clay retorts appear, from their greater porosity, to leak more than iron ones; but after working some months, the pores become clogged with carbon, and the porosity is thus greatly diminished, and the leakage is even less than in iron retorts working under the same pressure.[1] As the demand for clay retorts increased, the manufacture of them improved, an example of which improvement is well illustrated in the case of the retorts in the Great Exhibition of 1851, exhibited by Messrs Cowen of Blaydon Burn, near Newcastle-on-Tyne. When this firm first manufactured retorts about twenty years ago, each retort was made in ten pieces, which number was reduced to four, then to three, and then to two; and in 1844 the retort was made complete in one piece of the dimensions of 10 feet in length, and 3 feet in internal width. The clay of which these retorts are manufactured is exposed to the weather for some years, and is frequently turned over, and the fragments of fossils picked out, by which means most of the iron is got rid of, which in other fire-clays is so injurious. Some of these retorts are stated to have continued in active use for 38 months, thus exhibiting four times the durability of iron ones.

Brick retorts, or rather *ovens*, have also been introduced, and are said to be very durable, and to work satisfactorily. In one case the charge is 5 or 6 cwt. of coal every twelve hours, and the yield 9000 cubic feet of gas for one ton of Welsh coal, and from 10,000 to 12,000 cubic feet from one ton of Newcastle coal. The fuel required for the carbonization of the coal is said to be unusually large. Wrought-iron retorts, made of thick boiler plates firmly riveted together, have also been tried to a limited extent.

When clay retorts came into general use, the circumstance that they required a much higher heat than iron retorts suggested the economical plan of heating the clay retorts by the direct action of the furnace, and arranging the iron retorts in a separate oven, heated by the same furnace, or within a system of return flues, where they would be submitted to a less intense heat. By this means Mr Croll has found that with two furnace grates of 252 square inches in each, he has been able to carbonize in 24 hours five tons of coal in the clay retorts of one bench, and three tons and a half in the iron retorts of the same bench, with such an economy of fuel, that only 12 per cent. of all the coke made is required for the furnaces; whereas, in most of the London works, nearly one-third of the coke made is consumed in heating the retorts.

Fig. 3 represents one form of Mr Croll's method of combining iron and clay retorts. In this cross section *cc* are the clay retorts; the two uppermost are elliptical in form, and 16 inches by 12 in dimension; four are circular, each being 15 inches in inside diameter. Each clay retort is made in four pieces jointed with fire-clay. The furnaces are at each end of the retorts, one such furnace being shown at *g*, with its ash-pit *a*, and the retorts are arranged so as to receive an equal share of the radiated heat; *ii* are iron retorts in the lower oven, which receives the hot air through openings 14 inches by 10, in the lower arch, which separates the two ovens; *ff* are openings from the lower oven into the horizontal flues, which extend along the whole length of the retorts, and they are furnished with tile-dampers for the adjustment of the draught.

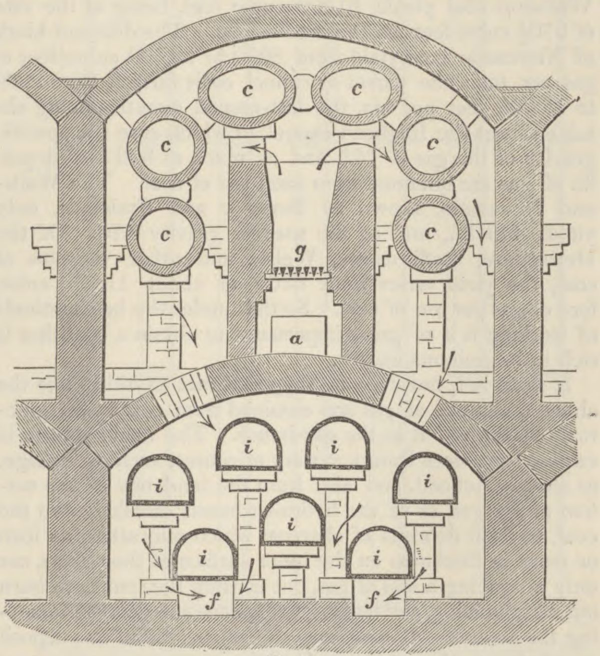

Fig. 3.

Quantity of gas yielded by coal.

The quantity of gas produced during the time the coal is undergoing decomposition is extremely variable. From a small retort, exposed for eighty-five minutes to a bright red heat, which was kept up with the utmost possible uniformity, the following results were obtained from eight pounds of the Wemyss coal:—

	Cub. Ft.	Cub. In.

---

[1] One of the greatest sources of loss in the manufacture of gas arises from the leakage, not only of the retorts and other apparatus within the works, but also of the mains, a loss amounting to from 10 to 30 and upwards per cent. Mr Croll estimates the loss at one-sixth of the gas sent out. The porosity of cast-iron pipes, not at their joints merely, but throughout their whole length, is evident from the saturation of the soil with gas in the immediate vicinity of the mains. Not only does the gas escape by exosmose into the air, but, by the reverse process of endosmose, air enters the pipes in some cases, as Professor Graham has found, to the extent of 25 per cent. Professor Brande thinks that the fetid odour of the soil in contact with the gas mains is due to the exosmose of ammonia, rather than of tar and naphtha, to which the ill odour is generally attributed.

At the time the process was terminated the extraction of aëriform matter had nearly ceased, so that the quantity of gas yielded by a pound of the coal was about five and a half cubic feet. The same coal carbonized on the large scale yielded, when the process was carried on for four hours, at the rate of four and one-third cubic feet of gas per pound. The weight of the coke in the above experiment was 32,050 grains; and as the weight of the gas, the specific gravity of which was ·65, must have been 15,026 grains, the tar and other residuary products, including the sulphuretted hydrogen abstracted by the process of purification, must have amounted to 8924 grains.

Quantity of gas obtained from different kinds of coal.

When the decomposition is effected on the large scale, the quantity of gas is found to vary with the quality of the coal, and the manner in which the operation is conducted. According to Mr Peckston, a chaldron of Newcastle Wallsend coal yields 10,000 cubic feet, being at the rate of $370\frac{1}{3}$ cubic feet per hundredweight. The different kinds of Newcastle coal yield from 8000 to 12,500 cubic feet of gas per ton; the parrot or cannel coals furnish from 9000 to 15,000 feet per ton, the last-named quantity being obtained from the Boghead cannel, in which case the specific gravity of the gas is ·752, and as much as 866 avoirdupois lb. of gas are obtained from each ton of coal. The Wallsend Newcastle, known as Berwick and Craister's, only yields 449 lb., and of the specific gravity ·470. Of the Derbyshire, Staffordshire, Welsh, and other varieties of coal, the yield varies from 6500 to about 11,000 cubic feet of gas per ton of coal. So that under the best methods of working it is of great importance to obtain a coal that is rich in bituminous matter.

It must not, however, be supposed that anything like the above quantities of gas are obtained from coal in the practical working of it in the gas-house. The manufacturer is exposed to losses from a variety of causes, such as leakage. as already noticed, and also from the tendency of the carbon of the gas, or of the hydro-carburets distilled from the coal, to form deposits of charcoal which may attain an inch or more in thickness on the inner surface of the retorts, not only producing a loss of gas, but causing the retorts to burn out more quickly, and leading to expense and delay in removing the deposit. It was formerly supposed that this deposit was owing to the overheating of the retort, or to an excess of heating surface. It was found. however. by Mr Grafton that the pressure to which the gas is subjected in the retort is the cause of the deposit. It is scarcely necessary to remark, that when an elastic body is generated in a close vessel, the pressure which it exerts upon such vessel depends greatly upon the resistance to which it is exposed in seeking to escape. In endeavouring to force its way by the dip-pipe through several inches of tar into the hydraulic main, the resistance thus offered produces a considerable pressure on the inner surface of the retorts. The passage of the gas through the washing vessels and lime purifiers increases this pressure, thereby promoting the deposit complained of, and causing an increased production of tar at the expense of the gas. Mr Grafton found that by working the retorts under a pressure of 14 inches of water, a deposit of carbon one inch in thickness was formed within the retorts in one week, and in the course of two months it filled up nearly one-fourth of the retort. On working the retorts with no other pressure than that produced by the insertion of the dip-pipe half an inch into the fluid of the hydraulic main, little or no deposit took place in the retorts in four months with the same kind of coal. It is now common at many gas works to introduce some kind of pumping apparatus, known under the name of the *exhauster* or *extractor*, between the hydraulic main and the condenser, or between this and the lime purifiers, by which means the pressure of the gas within the retorts can be reduced to any amount. It is, however, found desirable not to carry this reduction too far, lest atmospheric air should find its way into the retorts, and thus form an explosive mixture with the gas.

Quality of gas during different stages of the carbonization.

The quality of the gas yielded by coal varies greatly at different periods of the carbonizing process. The first products, when the coal has not been previously well dried, consist almost entirely of aqueous vapour and carbonic acid; these are succeeded by light carburetted hydrogen, olefiant gas, and sulphuretted hydrogen, which gradually diminish in quantity till towards the close of the process, when almost the only products are carbonic oxide and hydrogen. Hence, if the process be carried on too long, the gases obtained in the latter stages of it will not only be useless for the purpose of yielding light, but the fuel employed for their production will be expended in wasting the retorts to produce substances which are calculated to impair the illuminating power of the gases with which they are mixed. In the case of cannel coal, the interval between the charges of the retorts should not exceed three and a half or four hours; nor in the case of the Newcastle coal, which is not so easily decomposed, ought that interval to extend beyond six hours.

The Condensing Main and Dip Pipes.

Use of the condensing main and dip pipes.

From the retorts the gas, after its production, ascends by means of pipes, called *stand*-pipes, BB, figs. 4 and 5, into what is termed the *condensing main*, HH, which is a large cast-iron pipe, about twelve or fifteen inches in diameter, placed in a horizontal position, and supported by columns in front of the brickwork which contains the retorts, A. Wrought-iron hydraulic mains are now coming into use, and are preferable on account of their superior lightness and strength. This part of a gas apparatus is intended to serve a twofold purpose: First, to condense the tar and grosser products of distillation; and, secondly, to allow each of the retorts to be charged singly without permitting the

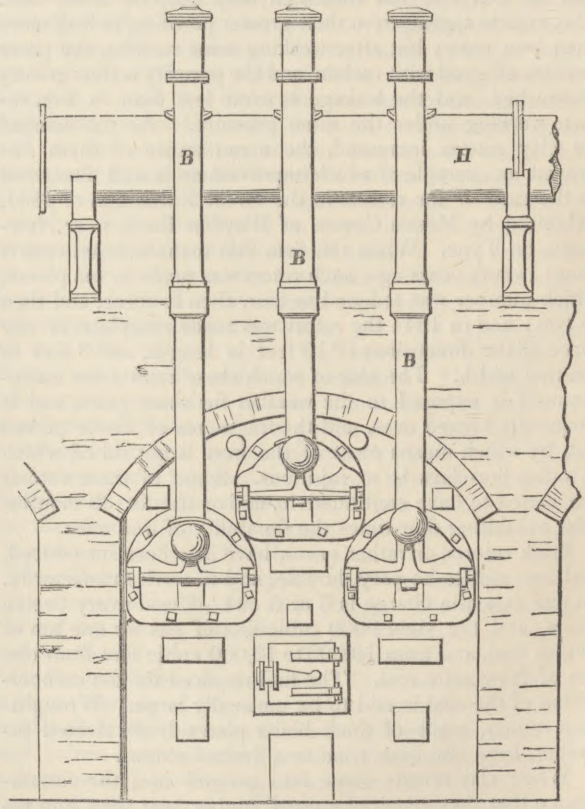

Fig. 4.

gas produced from the rest, at the time that operation is going on, to make its escape. To accomplish these objects, one end of the condensing main is closed by a flanch; and the other, where it is connected with the pipes for conducting the gas towards the tar vessel and purifying apparatus, has, crossing it, in the inside, a semi-flanch or partition, occupying the lower half of the area of the section, by which the condensing vessel is always kept half full of liquid matter.

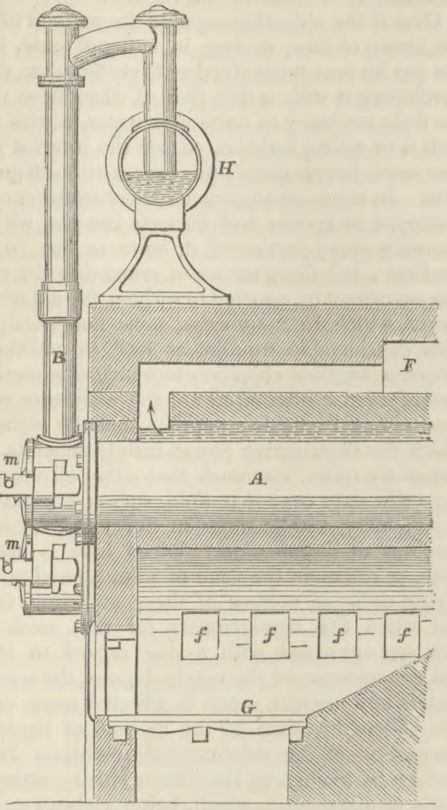

Fig. 5.

The stand-pipes, BB, are connected by a flanch with a branch-pipe rising from the upper side of the condensing main HH; and as the lower end of it dips about two inches below the level of the liquid matter, it is evident that no gas can return and escape, when the mouthpiece *m* of the retort is removed, until it has forced the liquid matter over the bend, a result which is easily prevented by making it of a suitable length. The upper part of the branch of the dip-pipe is generally furnished with a ground plug to allow the removal of the tarry matter, which is apt to accumulate in a concrete state at the lower part of the pipe where it is nearest the furnace. The dip-pipes vary in diameter from 3½ to 4 inches.

Of the Tar Apparatus.

Importance of the right construction of the tar apparatus.

After emerging from the lower end of the dip-pipe, the gas, now bereft of a considerable portion of the vapour of water, tar, and oleaginous matter, which ascends with it from the retort, is conveyed by pipes, for the purpose of being completely freed from these impurities, into contrivances where a more perfect condensation takes place. As the subsequent purification of the gas depends, in no small degree, upon the perfect separation of the tar and other condensible products by which it is accompanied, the construction of the vessels best calculated for attaining that end is a matter of the utmost importance; and indeed it may be justly affirmed, that unless that separation be effectually accomplished, the action of the chemical agents to which the gas is afterwards exposed, must be limited and imperfect.

The first contrivances employed for the purpose of condensation were all constructed on the supposition that the object would be best attained by causing the gas to travel through a great extent of pipes, surrounded by cold water, and winding through it like the worm of a still, or ascending upwards and downwards in a circuitous manner. An improvement on this form of condenser, and the one now in general use, is represented in fig. 6. It consists of a series of upright pipes connected in pairs at the top by semicircular pipes *ee*, and terminating at the bottom in a trough X Y containing water, and divided by means of partitions in such a way that as the gas enters the trough from one pipe it passes up the next pipe and down into the next partition, and so on to the end of the condenser. The cooling power of this air-condenser, as it is called, is sometimes assisted by allowing cold water to trickle over the outer surface of the pipes. In passing through these pipes the gas is considerably reduced in temperature, and the tar and ammoniacal liquor condense, the tar subsiding to the bottom, and the ammoniacal liquor floating on the surface. In the course of time the water in the trough is entirely displaced by these two gaseous products, and as these accumulate they pass off into a tar-tank, from which either liquor can be removed by means of a pump adapted to the purpose.

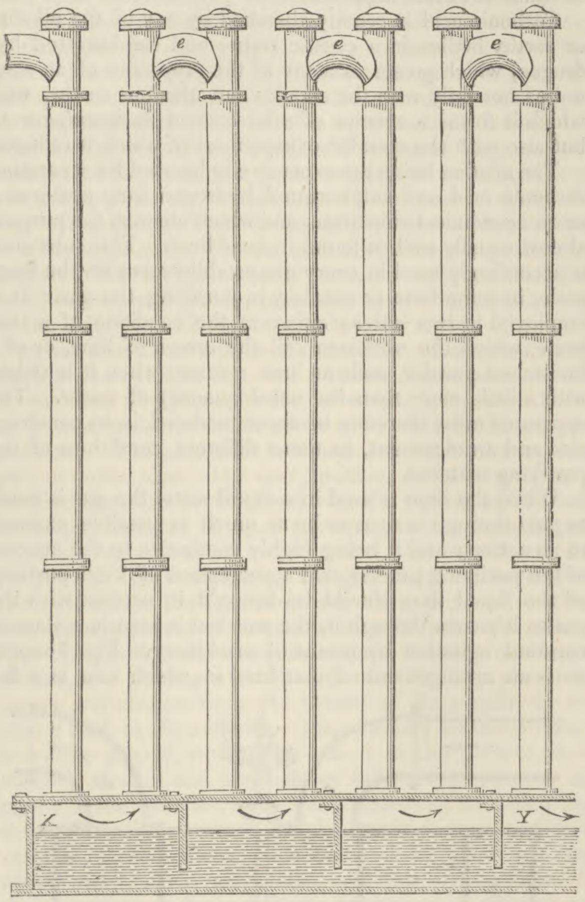

Fig. 6.

Of the purifying Apparatus for separating the Gases unfit for the purposes of Illumination.

Impurities of coal-gas.

With the two compounds of hydrogen and carbon, viz., olefiant gas and light carburetted hydrogen, which are yielded by coal during its destructive distillation by heat, several other products are obtained, which are not only useless for the purpose of illumination, but are calculated to diminish the brilliancy of the light which is afforded by these gases, and even to prove a source of serious nuisance during their combustion. Among these products of a deleterious nature are carbonic acid and sulphuretted hydrogen; and, in smaller quantity, carbonic oxide, nitrogen, and hydrogen. The first two are by far the most objectionable of these impurities; and fortunately their separation can be effected more easily than that of the others, the presence of which is of less importance.

How separated.

Carbonic acid is readily absorbed by any of the alkalies or earthy bodies in a caustic state; and sulphuretted hydrogen, which possesses many of the properties of an acid, unites not only with the alkalies and alkaline earths, with which it forms a species of salts termed *hydrosulphurets*, but also with the metallic oxides, most of which it reduces.

Different states in which lime is used for the purpose.

The alkalies being too expensive to be used for separating carbonic acid and sulphuretted hydrogen from coal-gas, a more economical substitute, and which answers the purpose almost equally well, is found in quicklime. This substance is accordingly used in every gas establishment on the large scale, in some form or another, in purifying the gas. It is employed in two states; either in the condition of a thin paste, which the workmen call the *cream* of lime, or of a moistened powder, such as lime assumes when it is slaked with a little more than the usual quantity of water. The apparatus must therefore be accommodated, in its construction and arrangement, to these different conditions of the purifying material.

Liquid lime, or cream of lime.

When the lime is used in a liquid state, the gas is made to pass through it so as to be as much as possible exposed to its action; and it being highly conducive to the success of the purifying process that a succession of fresh portions of the liquid lime should be brought in contact with the gas as it passes through it, the material is kept in a state of constant agitation by means of machinery. Fig. 7 represents an arrangement of that kind in which *aaa* is a flat cylindrical vessel in which the purification is performed, the gas entering by the pipe *c* and escaping by the pipe *d*. In the inside of this vessel is another of a similar form *ff*, terminating at the bottom in a broad horizontal flanch or circular plate *gg*, and having revolving within it an agitator *hh*, which works in an air-tight stuffing box. The gas being forced by the pressure from the retorts or from the exhauster to descend below *g*, is more effectually exposed in its progress to the action of the lime by the commotion produced by the agitator, and finally ascends, in a purified state, through the pipe *d*. Fresh portions of the purifying material are supplied from the vessel *k* by means of the connecting pipe *b*; and the cream of lime, after being saturated with the impurities, is withdrawn at *e*. In large establishments the gas is forced in succession through several vessels of the kind described, the cream of lime being changed in each of them at different times, to render its action more uniform and regular.

Purification promoted by agitation.

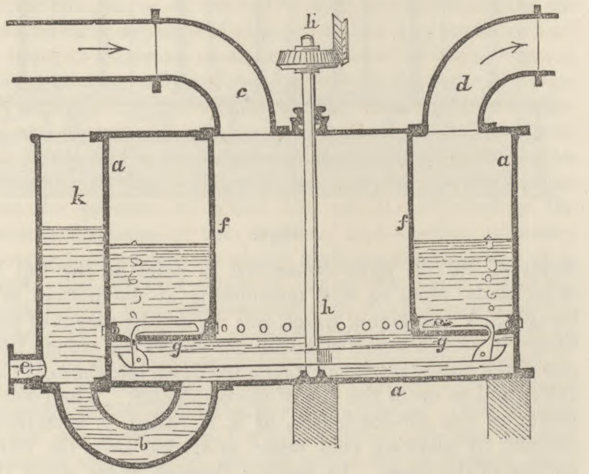

Fig. 7.

Objections to the use of lime in the liquid state.

One of the objections against the method of purifying by the cream of lime, or lime in a liquid state, is, that unless the gas be previously freed entirely from tar, that substance enveloping it with a thin film of oleaginous matter, which has little tendency to unite with water, carries the gas along with it in rolling bubbles, so that the internal parts of it can thus scarcely ever come into contact with the purifying materials. In some arrangements mechanical contrivances are employed to agitate and disperse the gas, with the view of exposing every portion of it, more or less, to the action of the lime; but these modes of promoting the efficacy of the process cannot be resorted to without the aid of some moving power, which, in many cases, must necessarily be attended with considerable trouble, as well as additional expense. There is another objection to which this method of purification, even if it required not the assistance of machinery, must always be liable; namely, that the olefiant gas, upon which the illuminating power mainly depends, is largely absorbed by water, insomuch that either oil or coal gas, standing a few days over that fluid, suffers a great deterioration of its quality, and becomes in every respect less fit for the purposes of illumination. When lime is used in the dry state, or rather in the state of a moistened powder, for purifying coal-gas, neither of these objections is applicable; and when the arrangements for that mode of purification are contrived with a due regard to the simplicity and convenience of the manipulations, the separation of the useless and noxious gases is effected more easily, and not less effectually, than by the method of liquid lime. The abstraction of the sulphuretted hydrogen becomes more perfect by adding to the lime a small portion of the peroxide of manganese, which, being a cheap substance, adds very little to the expense of the process. This method of purifying coal-gas having been adopted with success in most gas establishments, we shall now proceed to explain the nature of the apparatus by which it is carried into effect.

Apparatus for dry lime.

Fig. 8 represents an elevation in section of a dry lime purifier. The gas is admitted by the pipe A into the bottom of a rectangular iron vessel, about three feet deep: over the mouth of the inlet pipe is a plate of iron B, which serves to spread the gas, and to prevent the lime from falling into the pipe. In some cases this vessel is divided into two compartments by means of a partition extending nearly to the top, in which case the gas filters up through one compartment and down through the other, passing each way through layers of lime, L L, placed on iron gratings or on perforated shelves, S S, of cast-iron, 7 or 8 inches apart. The perforations are each $\frac{5}{8}$ths inch in diameter and $\frac{3}{4}$ths inch asunder. The vessel is covered with a light lid of sheet iron, the border of which dips into a narrow vessel of

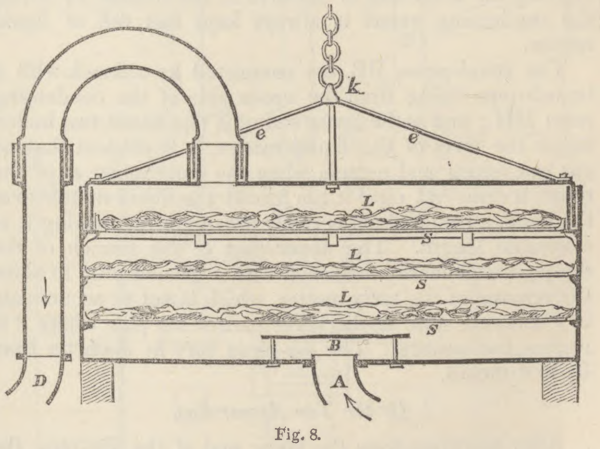

Fig. 8.

water, thus forming a secure water-joint or water-lute. The lime is fresh slaked and slightly moistened, and is placed on each shelf to the depth of about 3 inches; it is then sprinkled with water from a watering-pot. It is stated that a bushel of quick lime is sufficient for the purification of 10,000 cubic feet of gas. By slaking and reducing it to powder its bulk is more than doubled: two bushels of hydrate of lime thus formed cover a surface of 25 square feet to a depth of 2½ inches. At some works a bushel of slaked lime, or half a bushel of unslaked lime, is allowed for every ton of coals distilled. Some engineers estimate that 40 lb. of lime are required for every 10,000 cubic feet of gas from average Newcastle coal. If more lime is required the coal must have been damp, or have contained more than the usual proportion of sulphur. Good Newcastle coal contains about one per cent. of sulphur; some kinds of *cannel* only one-half per cent. The capacity of dry lime purifiers is calculated on the assumption that 25 square feet of surface are required for 10,000 feet of gas. The purifiers are generally arranged in a set of four, three of which are usually at work while the fourth is being emptied. In fig. 8, D is the exit pipe, leading to the second purifier. In emptying one of the purifiers the cover is raised by means of the chain *k*, attached to the light rods *e e*, and the shelves are also moveable, the upper ones being taken out while the lower are charged. The spent lime contains hydrosulphuret of ammonia, and when exposed to the air it evolves sulphuretted hydrogen, carbonic acid taking its place. The poisonous liberated gas thus becomes a nuisance to the neighbourhood, but it is sometimes got rid of before the purifier is emptied, by connecting each purifier with a large horizontal pipe which opens into the chimney-shaft of the retort-house, the powerful draught of which draws off all volatile matter from the lime, air instead of gas being let in at the bottom. The cover of the purifier can then be raised, and the lime be removed without annoyance to any one. The lime is burned in ovens, and is used a second time in the purifiers, after which it becomes refuse.

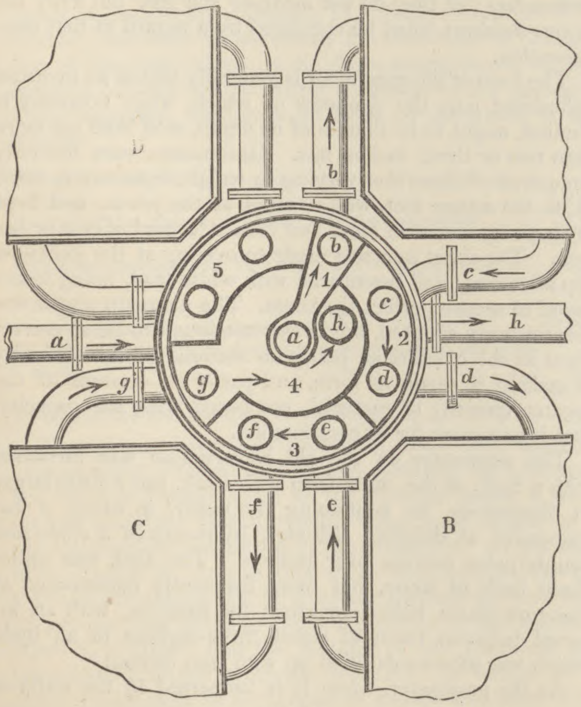

Fig. 9.

An ingenious form of purifier, contrived by Mr Malam, consists of a central valve and cover, and four vessels, A, B, C, D, fig. 9, placed around it. The central valve consists of an iron cylinder, 4 feet 6 inches in diameter and 3 feet deep, supported on brick piers; the bottom is perforated with ten holes for the reception of pipes leading to and from the four purifiers, and also for the main inlet and outlet pipes. Each purifier is 5 feet square and 3 feet 6 inches deep,—it contains seven layers of lime, supported on sieves of wire, or slitted plates of iron. Each purifier has a cover with short sides dipping into a water groove, and the central cylinder has also a cover fitting within it in such a way as to communicate with the pipe *a*, and either of the 4 inlet pipes, and also to communicate between one of the outlet pipes and the pipe *h*, which carries off the purified gas. The inlet pipes, *b*, *d*, *f*, admit the gas from the central case to the bottom of the purifiers; and the outlet pipes, *c*, *e*, *g*, return the gas from the purifiers back to the case, after having passed up through the layers of lime, and descended at the back of a partition plate in each purifier to the outlet pipes at the bottom. *a* is the main inlet pipe for conveying the gas from the scrubber or the condenser, and *h* is the main outlet pipe for conveying the gas to the gas-holder. The central cylinder contains water to the depth of 10 inches, and the ten pipes rise up through the bottom to the height of 12 inches, so that the mouth of each is 2 inches above the surface of the water. The cover which fits into the cylinder is 4 feet 3 inches in diameter, and is divided into five parts, the first of which, 1, fits over the inlet pipe *a*, and over either of the inlet pipes leading to the purifiers. The partitions 2, 3, and 5 fit each over an inlet and an outlet pipe, while one partition, 4, fits over one outlet pipe from one purifier, and over the pipe *h*, which leads to the gas-holder. In fig. 9 the arrangement is such as to open a communication between the inlet pipe *a* and the purifier A. Now supposing the gas to have passed from the scrubber or the condenser into the centre of the cylinder, its only means of escape is to pass down the pipe *b* into the purifier A, where it ascends through the layers of lime, and passing over the top of a dividing plate, descends and escapes from the bottom of the purifier by the pipe *c* back to the cylinder. Here its only means of escape is by the pipe *d*, which conducts it to the purifier B, in which it ascends and descends as before, returning by the pipe *e* to the cylinder, whence it proceeds by the pipe *f* into the purifier C, then along the pipe *g*, which is shut off from communication with any pipe except *h*, by which it is conveyed away to the gas-holder. By this arrangement the three purifiers A B C are being worked, while a fourth purifier D is being emptied and re-charged with lime. When it is found, on testing the gas, that the lime is unfit for its office, the purifier A is thrown out of work, and D is brought in. The frame is then shifted so as to bring the triangular division 1 over *d*, by which means B C D will be the working purifiers, and A will be thrown out of use. In this way, by shifting the frame round its centre over each of the four outlet pipes, any three of the purifiers can be brought into action. At the top of the frame is an upright shaft with a screw cut upon it, which works the frame up, by turning a lever which has a corresponding thread. The position of the triangular partition is then ascertained, and the communication from one purifier to another can be changed in a few minutes.

Quantity of lime necessary for purifying gas.

The quantity of lime necessary for purifying a given volume of coal-gas varies, as already stated, with the quantity of sulphur contained in the coal from which the gas is produced. It is proper, however, to examine at intervals, during the progress of the purification, the state of the gas by such chemical tests as are calculated to detect the presence of any of the deleterious substances with which it is usually contaminated. Thus carbonic acid is readily discovered by agitating a small portion of the coal-gas with lime water in a limpid state, the solution being quickly rendered turbid when the most minute quantity of that gas is present. Sulphuretted hydrogen is discovered with equal facility by causing a small current of coal-gas to play against a slip of paper moistened with a weak solution of acetate of lead, or nitrate of silver, both of which instantly become black when they are exposed to the action of sulphuretted hydrogen.

Of late years a variety of improvements have been introduced for purifying gas, which we now proceed briefly to notice. They are at present only in partial use, but are likely to lead to important results. Indeed the chemistry of the manufacture is just now in a transition state, and is receiving considerable attention from scientific men.

After the tar and ammonia have been for the most part extracted from the gas by the condenser, a further separation of ammonia is now frequently effected by passing the gas through layers of coke dust, cinder or breeze, or brick-dust, placed in trays or sieves, six or eight inches apart, in a vertical hollow shaft, and as the gas streams up through the porous column the ammonia is retained. This *scrubber*, as it is called, is sometimes used in conjunction with a washing vessel, and sometimes the latter only is employed, with the advantage of separating a portion of sulphuretted hydrogen and carbonic acid as well as the ammonia; but the wash-vessel is said to remove much of the olefiant gas, the illuminating power of which is very high; an objection which does not apply to the scrubber. Mr Croll has patented a method of separating ammonia by means of chloride of manganese, which has the effect also of removing much of the sulphide of carbon, of producing a saving of one-half or one-third of the lime required in the subsequent process, while a valuable product is formed by the chlorine of the manganese uniting with the ammonia, to form sal-ammoniac. Ammonia has also been separated by passing the gas through dilute sulphuric acid, the resulting sulphate of ammonia being also a valuable secondary product. The ammonia may also be separated by means of sulphate of manganese, chloride, or sulphate of zinc.

Formerly a good deal of ammonia passed off with the gas to the consumer, to the great injury of the gas meter, the gas fittings, and the furniture of houses. After the ammonia has been separated, the gas is passed into the dry-lime purifiers, which are preferable to the wet-lime, not only for the reasons already stated, but on account of the less amount of pressure required to force the gas through them. The objection to dry lime is on account of the volatile nature of the offensive hydrosulphide of ammonia, which is only mechanically combined with it, so that when the purifiers are opened, and the spent lime taken out, the oxygen of the air combines with the hydrosulphide, evolving great heat, and filling the neighbourhood with noxious odours. This serious objection is now obviated by getting rid of the ammonia between the condenser and the purifier: the salts separated by the dry lime are then no longer volatile, but, on the contrary, the spent lime becomes in some cases a valuable manure, consisting, as it does, of sulphate, carbonate, and cyanide of lime.

A method of purifying the gas, patented by Mr Hills of Deptford, is now attracting considerable attention. It is based upon the property of the hydrated oxide of iron to decompose sulphuretted hydrogen, a portion of the sulphur forming a sulphide with the iron. Quicklime is also used to separate carbonic acid, and the oxide of iron is mixed with sawdust or cinders (breeze) for the purpose of increasing the surfaces of contact, and this mixture is placed in the purifiers. When a sufficient quantity of gas has passed through it the purifiers are opened, and the mixture is exposed to the air, under which new condition it combines with oxygen, and again becomes fitted for use in the purifiers. The chemical changes which occur in these operations are the following:—The mixture of hydrated oxide of iron, &c., absorbs sulphuretted hydrogen $Fe_2O_3 + 3HS = Fe_2S_3 + 3HO$. The sulphide of iron, by exposure to the air, absorbs oxygen, and the sulphur is separated in an uncombined form $Fe_2S_3 + O_3 = Fe_2O_3 + S_3$. The mixed material can be again employed in the purification of the gas, and the process may be repeated until the accumulation of sulphur mechanically impairs the absorbent powers of the mixture. The sulpho-cyanogen which accompanies the gas is retained by the oxide of iron, and gradually accumulates in the mixture.

Chemists have also sought for substitutes for lime, or for means of diminishing the amount usually required. M. Penot recommends sulphate of lead for separating sulphide of hydrogen. Professor Graham proposes to add to the slaked lime one equivalent of crystallized sulphate of soda, which would absorb sulphide of hydrogen until two equivalents thereof were absorbed by one equivalent of lime; the lime is converted into sulphate, and the soda becomes bi-hydrosulphuret, which might be readily washed out of the lime, and again be converted into soda by roasting, and thus be used over and over again to mix with the lime. The secondary product formed in the manufacture of chloride of lime, viz. the mixture of chloride of manganese with sulphate of soda, has also been used as an efficient gas-purifier.

Gasometers for receiving and containing the Gas before it is consumed.

Capacity of gasometers.

As many disadvantages would be experienced by attempting to adjust the production of the gas to the rate of its consumption, it is found to be more convenient, as well as more economical, to store up such a portion of it during the day as shall compensate for the deficiency of the supply that may be furnished during the time the gas is being consumed in the course of the evening. The capacity of the vessels used for this purpose, which are incorrectly called *gasometers* (for they do not *measure* the gas, but only act as *gas-holders*), must be regulated by a regard to that consideration.

Best form of.

The form of the gasometer is generally that of an inverted cylindrical cup, the diameter of which, when economy is studied, ought to be double of its depth, or at least not more than two or three inches less. Gasometers were formerly composed of sheet iron varying in weight from two to three lb. to the square foot, well rivetted at the joints, and kept in shape by means of stays and braces formed of cast or bar iron. The sheet iron was made to overlap at the joints—a slip of canvas, well besmeared with white lead, being interposed to secure perfect tightness. The prismatic shape was also formerly adopted, but it was not found to be so convenient as the cylindrical, partly on account of the difficulty of making it retain its form, and partly on account of the greater quantity of material, compared with the capacity, that is necessary for its construction.

Tank of gasometer.

The gasometer on the old construction was furnished with a tank, of the same form with itself, but a little larger in dimensions, for containing the water, in which it was suspended at different altitudes, by means of a chain and counterpoise moving over pulleys. The tank was sometimes built of stone, but more frequently constructed of cast-iron plates bolted together by flanches, with an interval between them of about three-eighths of an inch, which was afterwards filled up with iron cement.[1]

As the gasometer, when it is immersed in the water of the tank, suffers a loss of weight equal to that of the portion of fluid which it displaces, it is evident that unless some arrangement be made to counteract the varying pressure which must thus result from the different depths to which it may be immersed, the gas contained in the gasometer will be expelled, at different times, with a varying force. If, however, the weight of the chain of suspension, or rather the weight of that portion of it whose length is the same as the height to which the gasometer ascends, be equal to half the loss of weight which the gasometer sustains by immersion in water, a perfect compensation will be made, and an equilibrium will hold between the gasometer and its counterpoise at all altitudes. Thus, if the weight of the gasometer were five tons, or 11,200 lb., and it lost by immersion a seventh part of its weight, or 1600 lb., then the weight of that portion of the chain equal in length to the highest ascent of the gasometer would require to be 800 lb., and the weight of the counterpoise 11,200 – 800, or 10,400 lb.

---

[1] The following iron cement is recommended by Peckstone:—Take iron turnings or borings, and pound them in a mortar till they are small enough to pass through a fine sieve; then, with one pound of these borings, so prepared, mix two ounces of sal-ammoniac in powder, and one ounce of flowers of sulphur, by rubbing them well together in a mortar; and afterwards keep the mixture dry till it may be wanted for use. When it is so, for every part thereof, by measure, take twenty parts of iron borings, prepared as above mentioned, and

	lb.
For, the gasometer being immersed, its virtual weight is 11,200 – 1600, or	9,600
Weight of portion of chain now acting with the gasometer	800
Sum is the weight of counterpoise	10,400

Again,

The gasometer being elevated out of the water, its weight is	11,200
Weight of chain now acting in opposition to it	800
Difference is the weight of counterpoise	10,400

Although the compensation, by this adjustment of the weight of the chain, answers the purpose in the most effectual manner, the following method is by some deemed preferable. Let the counterpoise consist of a long cylindrical or prismatic body, having the area of its horizontal section equal to the area of a similar section of the plates of the gasometer, and be allowed to descend into the water as the gasometer rises out of it. Also let the chain be of a weight equal (length for length) to a column of water of equal bulk with the counterpoise. Then, if the weight of the gasometer be, as already supposed, 11,200 lb., the weight of the counterpoise must be the same; but the weight of that portion of the chain which, by the above arrangement, was only equal to half the loss of weight sustained by the gasometer when immersed, must now be equal to the whole of that weight.

	lb.
Then, the weight of the gasometer in the water is, as before	9,600
Weight of the chain now acting with the gasometer	1,600
Weight of counterpoise, now out of the water	11,200

Again,

The weight of the gasometer, out of the water, is	11,200
Weight of the chain, now acting in opposition to the gasometer	1,600
Weight of the counterpoise, in water	9,600

Pressure for expelling the gas.

Though we have only shown, in both these modes of compensation, that an equilibrium between the gasometer and its counterpoise holds in the extreme cases, it would be easy to prove that the same thing must subsist at all the intermediate elevations of the gasometer. At the same time, it must be obvious that these contrivances, however well calculated they may be to secure the equilibrium alluded to, can have no effect in expelling the gas; and therefore, when it is wished that the contents of the gasometer shall issue from it under a certain pressure, the weight of the counterpoise must be diminished to a suitable extent. Thus, if it were required that the pressure employed for expelling the gas should be equal to that produced by a column of water three-fourths of an inch deep, then it would be necessary to diminish the weight of the counterpoise by the weight of a column of water having the same diameter with the gasometer, and an altitude of three-fourths of an inch. If the diameter of the gasometer above mentioned were, for example, 35 feet or 420 inches, the weight of a cylindrical portion of water having that diameter. and a depth of three-fourths of an inch, would be, in grains,

$$420^2 \times {\cdot}7854 \times \tfrac{3}{4} \times 252{\cdot}5 = 26236876 \text{ grs. or } 3748 \text{ lb.}$$

Hence it would be necessary to make the counterpoise 3748 lb. lighter than it was supposed to be according to the above-mentioned arrangements, in order that the gas might issue from the gasometer under a pressure of three-fourths of an inch of water. If the calculation were conducted with extreme accuracy, the specific gravity of the gas ought also to be taken under consideration; but the object to be attained is not of so delicate a nature as to require an attention to such minute circumstances. Besides, we shall afterwards find that the value of the arrangements we have described for obtaining a uniform and equable pressure is greatly diminished; and these are even entirely superseded by a contrivance called the governor, to be afterwards explained.

Such is the old method of constructing gasometers. Of late years, however, a different system has prevailed. Instead of making them of heavy plate iron, strengthened by angle iron and stays, and of so great a weight as to require the above-described complex system of equilibrium chains and counterbalancing weights to relieve the gas from the great pressure to which it would otherwise be subjected, the gas-holders are now made so light that they actually require to be loaded in order to supply the required pressure. The practice has even been introduced of not suspending the gas-holders at all, but regulating their rise and fall by means of guide rods placed round the tank. Fig. 10 represents a section of a modern gas-holder, in which will be seen a contrivance for getting rid of a large body of water in which the gasometer was formerly sunk, and which was found inconvenient in frosty weather, when, to prevent freezing, it was necessary to introduce steam. The objections to the contact of a large body of water with the gas have been already referred to. By using a central core of masonry, brickwork, earth, or sheet iron, the large volume of water is got rid of—the only water required being that contained in the ring-shaped space or tank, TT, round the core. Small

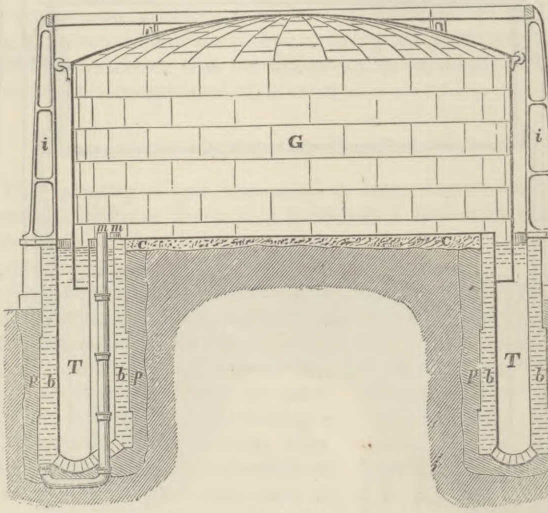

Fig. 10.

---

mix them well together in a mortar or other iron vessel. The compound is to be brought to a proper consistency by pouring water gently over it as it is mixing; and when used it must be applied between the flanches by means of a blunted caulking iron.

gas-holders on this construction may be suspended from the centre by a chain, while to the pillars of the triangular or polygonal cast-iron frame, *ii*, guiding rollers are attached to facilitate the motion of the cylinder, and to keep it horizontal. In forming the tank, TT, the brick-work and the mortar joints must be perfect, or the core will soon be injuriously acted on by the water. When the whole of the core is not built up, but a solid mass of earth is left in the middle, it is first dressed to the proper shape, and the slope is usually puddled, as at *p*. The brick-work, *b*, is carried up in Roman cement, or in the best hydraulic mortar, and it is recommended that the puddle behind the brick-work be clay, with a portion of sand or silt. The surface of the core is covered with concrete, *cc*. On one side of the tank is a well, containing the inlet and exit pipes, *mm*. The inlet pipe enters at the top of the well, and passes to the bottom of the tank, where there is a vessel for the reception of any tar or moisture that may by chance be conveyed by the gas: this pipe then passes horizontally through the brick-work, and rises up vertically through the water, so that its mouth may be about two inches above the surface. The outlet pipe stands by the side of the inlet pipe, and, descending through the water, passes out through the wall of the tank into the stand-pipe well, where there is another receptacle for tar and water: this pipe proceeds up the well either to the governor or to the main.

Particular forms of gasometer.

In situations where a sufficient depth of the tank cannot be easily obtained, an expedient may be resorted to, such as is represented in fig. 11, and known as the *telescope* gasometer. It consists of two, or even three parts, separable from each other; the one having the form of the common gasometer, and the other being open at the top as well as the bottom, but connected with the other by a channel running around the bottom, which is filled with water. The lower part has a recurved form at the top; and this portion of it entering into the channel becomes water-luted, by which the entire gasometer is rendered air-tight at the line of junction. When the gas passes in by the inlet pipe the inner cylinder rises first, and when its lower edge nearly reaches the surface of the water its curved flange catches the flange of the next cylinder, which also rises, and when this has risen to the proper height it catches the third cylinder if there be one, and raises it also. The water contained in the lower flange of each cylinder effectually prevents the escape of the gas or the entrance of atmospheric air.

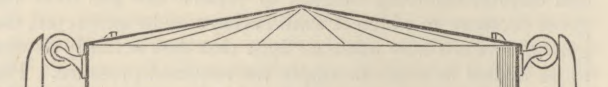

Fig. 11.

Pipes for introducing and discharging the gas.

The pipes by which the gas is commonly introduced and conducted off being in many cases considerably below the level of the street pipes with which they communicate, are apt to be filled up in the course of time with the condensed water which passes off in a vaporous state with the gas. To remedy this inconvenience, it is necessary to place vessels for receiving that water in connection with the entrance and exit pipes, so contrived that the accumulated water may be easily removed from them when required. One of these vessels, which are improperly termed *syphons*, is represented by fig. 12. When the water rises to the height *d*, *e*, it is drawn off by means of a small suction pump, introduced into the pipe *ac*, which reaches within about an inch of the bottom of the syphon. To prevent too much water being removed, and thus allowing the gas to escape at *ac*, the lower end of the pipe of the suction pump should be perforated with small holes to as great a distance as the water is to be left in depth; or, if deemed preferable, the upper end of the pipe *ac* may be rendered air-tight by a screwed cap.

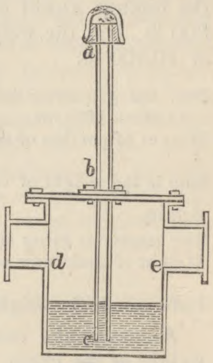

Fig. 12.

When access to the bottom of the tank is difficult, swivel or flexible-jointed tubes, disposed so as to rise and fall with the gasometer, are sometimes resorted to. Jointed tubes, connected by means of water-lutes, are also occasionally employed, and they are found to answer the purpose in situations where the water is not exposed to frost.

Of the Main and Service Pipes.

The gas being duly purified and prepared for combustion, the next point to be considered is the transmission of it from the gasometer to the various places where it is to be consumed. As it must sometimes be conveyed, particularly in the case of large establishments, to the distance of several miles, it is evident that unless the diameters of the various pipes through which it is to be conducted have a due relation to the quantity of gas to be transmitted, there will be a danger either of incurring an unnecessary expense, by making the pipes too large; or, what is still worse, of being exposed to a deficiency of supply, by making them too small. The first object, therefore, to be ascertained by the engineer, is the probable number of lights that may be required in the various streets and lanes in which these pipes are to be laid; and these being known, the corresponding quantity of gas, according to the quality of it, may be afterwards computed. With regard to the relative dimensions of the pipes at different distances from the gaswork, the only general rule to be observed is, that the sum of the areas of the sections of the main pipes proceeding immediately from the gasometer should be equal to the sum of the areas of the sections of the various branch-pipes which they supply with gas; and this rule, with some little modification, should be followed in the case of the subordinate ramifications.

Dimensions of pipes.

In the case of good coal gas, we may safely reckon that one-fourth of a cubic foot of it will furnish the light of a moulded candle for an hour, of which one pound will, when the candles are burnt in succession, last forty hours. On this supposition, and assuming that the pressure upon the gas in the gasometer is equal to three-fourths of an inch of water, the diameters of pipes necessary for conveying various quantities of gas may be stated as follows:—

Diameters of main pipes.

Diameter of Pipe in Inches.	Quantity of Gas in Cubic Feet per Hour.	Equivalent Number of Candles.
¼	4	16
½	20	80
¾	50	200
1	90	360
2	380	1,520
3	880	3,520
4	1,580	6,320
5	2,480	9,920
6	3,580	14,320
7	4,880	19,520
8	6,380	25,520
9	8,090	32,360
10	10,000	40,000

This table has been deduced partly from theoretical considerations, and partly from the results of experiment. Peckstone affirms, in his work on Gas-lighting, that a pipe ten inches in diameter, is capable of transmitting 50,000 cubic feet of gas per hour, under a pressure of one inch of water; while, according to the statement of Mr Creighton, such a pipe would scarcely convey the tenth part of that quantity, under a pressure of from four-eighths to three-fourths of an inch of water. It is impossible to reconcile these discordant statements either by an allowance for the difference of pressure or the difference of the specific gravities of the gases; for it ought to be kept in view that the discharge of gas is directly proportioned to the square root of the height of the column of water by which it is pressed, and inversely as the square root of the specific gravity of the gas. Both of these propositions, however, must be greatly modified by friction, and consequently by the length of the pipes through which the gas is conveyed. In the supply stated to be furnished by pipes of different dimensions, we have deemed it safest rather to underrate the quantity than overrate it.

The main-pipes are usually made of cast-iron, joined together with socket-joints, in lengths of three yards. The depths of the sockets vary in pipes of different sizes from three to six inches, part of them being fitted with gasket to bring the centres of the pipes into line, and the remainder with lead after the gasket has been driven home with suitable chisels or caulking irons. The depth of lead to secure a good joint should not be less than an inch and a half; the interval between the spigot and socket being from three-eighths to seven-eighths of an inch, according to the diameter of the pipe. Joints are now frequently made without lead. One plan is to caulk into the bottom of the socket, to the depth of two inches, white rope-yarn covered with putty, and to nearly fill up with tarred gaskets, leaving a *gate* into which is poured a composition of melted tallow and vegetable oil. Another plan is to bore the socket of the pipe with a slightly conical opening, the small end being similarly turned to fit the socket. The two ends of the pipe are coated with a mixture of white and red lead, and being brought together, are driven home by a mallet. Such a joint is said to be quite tight. Rings of vulcanized India rubber have also been recommended for the joints of gas and water pipes.

Necessity of giving pipes a proper inclination.

As a considerable quantity of water is carried off by the gas in the state of vapour, which is afterwards condensed in the pipes, some arrangement must be made for its collection and occasional removal; and accordingly, in laying the pipes, care must be taken to give them a regularity of declivity towards one or more points, where proper syphons, close vessels, and cocks must be placed, to receive and discharge the collected water. When these precautions are neglected, or when the levels are inaccurately taken, much annoyance is experienced; and as the evil can only be corrected by lifting and rejoining the pipes, the utmost attention should be paid to guard against it at first.

For stopping off the gas in large pipes, valves luted with water or mercury, according to the degree of pressure to be resisted, are usually employed. One of the most simple forms of these valves is represented in fig. 13, where *aa* is the valve, having the shape of an inverted cylindrical cup, which is raised and depressed by a rod *c* passing through an air-tight stuffing-box; and *bb* an annular cavity or interval, partially filled with water or mercury, into which the valve descends when it is shut.

Service pipes.

To convey the gas from the main-pipes, and distribute it through the various apartments of dwelling-houses, pipes made of block-tin are generally used; these being more durable and better adapted to the purpose than pipes composed of copper or any other metal. In arranging the interior fittings, the same precautions must be observed as were recommended in the case of the main-pipes, viz. to give the various branches a due degree of inclination, so as to cause all the condensed water to flow to one or more points, where proper cocks must be placed for its removal. Unless this be done, the lights will be apt to flicker, or be extinguished at times altogether. Nor is it of trivial moment to enjoin the workmen, when they are soldering the service-pipes, to avoid with the utmost care allowing any of the melted metal to find its way into the inside of the pipes; it being in a great measure to this circumstance that the deficiency in the supply of gas, so frequently complained of, is owing.

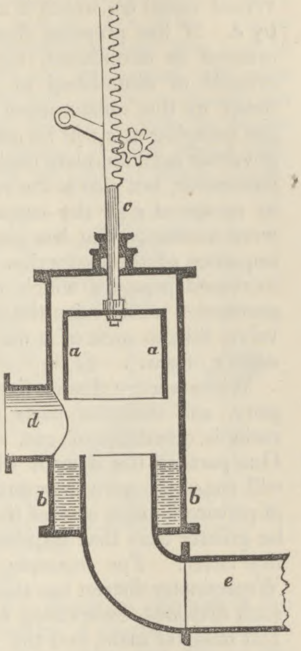

Fig. 13.

Of the Governor or Regulator.

Use of regulator.

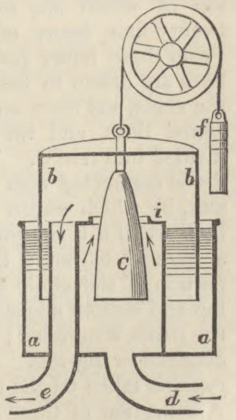

Fig. 14.

The quantity of gas consumed in large towns varying greatly at different times, it is evidently a matter of some importance to the public, as well as to the manufacturers of gas, that the supply of it should be duly adjusted to the consumption; so that when the lamps are once regulated to a proper height of flame, they may continue afterwards to burn with the same steady light throughout the whole of the evening. Any contrivance that can accomplish so desirable an object must save a great deal of trouble to the consumer of gas, and much unnecessary waste of it to the manufacturer; and such is the design of the governor or regulator. Fig. 14 represents one of these contrivances, *d* being the pipe proceeding from the gasometer, by which the gas is admitted, and *e* the pipe by which it escapes; *c* is a valve of conical form, fitted to the seat *i*, and raised and depressed by means of the weight *f* attached to a cord passing over a pulley; *bb* is a cylindrical vessel formed of sheet iron, which ascends and descends in the exterior vessel *aa*, in which water is contained to the level represented. The gas, entering at *d*, passes through the valve, fills the upper part of the inverted vessel *bb*, which it thus partially raises, and escapes by *e*. If the pressure from the gasometer be unduly increased or diminished, the buoyancy of *bb* will be increased or diminished in like proportion, and the valve being by this means more or less closed, the quantity of gas escaping at *e* will be unaltered. And not only will the governor accommodate itself to the varying pressure of the gasometer, but also to the varying quantities of gas required to escape at *e* for the supply of the burners. Thus, if it were necessary that less gas should pass through *e*, in consequence of the extinction of a portion of the lights, the increased pressure which would thus be produced at the gasometer would raise the governor, and partially shut the valve, till the state of it was duly adapted to the requisite supply of gas.

Pressure indicator.

When a large district is supplied by a single gas company, and different parts of the same district consume variable quantities of gas, variable pressures are required. One part of the district where there are numerous shops will consume more than another part which consists chiefly of private houses, so that the pressure for the former must be greater than that required for the latter. For example, the Westminster district has about 20 such divisions, comprising nearly 150 miles of main, and the varying pressures required for each division are managed as follows:—In the superintendent's room there are a number of small gasometers called *pressure indicators*, and over each is the name of the sub-district to be supplied. Each gasometer (A, fig. 15) is about 12 inches in diameter. It is supported in a tank of water in such a manner that it can rise and fall with the varying pressure in the mains with which it is connected by the pipe B. At the upper part of the gasometer is a rod C, carrying a black lead pencil, which bears upon a cylinder D, which is covered with a sheet of paper, along the top of which are marked the twenty-four hours of the day. From these hours perpendicular lines are drawn to the bottom of the sheet, and there are also horizontal lines, and the bottom is divided into tenths. The cylinder is connected with a time-piece, so as to rotate on its axis, by which means the pencil draws a line opposite the hour when it is set going. If the pressure be constant for a number of hours, the pencil will of course describe a portion of the circle round the cylinder parallel with the top and bottom edges of the paper, or a straight line when the paper is unrolled; if the pressure vary, the line will be diagonal or zig-zag. At the end of twenty-four hours the paper is taken off the cylinder, and replaced by a new one. A collection of these papers for each district furnishes an index to the supply of gas at any hour of the day to the the sub-district to which it refers.

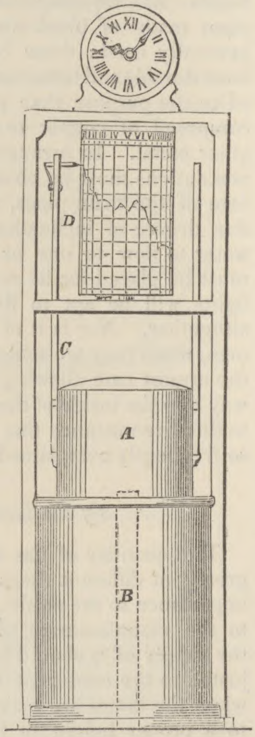

Fig. 15.

Gauge.

It is often necessary to ascertain the pressure to which the gas is subjected in the various forms of apparatus used in the manufacture. For this purpose a simple gauge is attached thereto, consisting of a bent graduated glass tube, containing a portion of water or of mercury, as shown in fig. 16. If one end of the tube be screwed into a vessel or an upright pipe as in the figure, containing gas of the same pressure as that of the external air, the liquid will stand at the same height in the two limbs of the gauge. If the pressure of the gas be greater than that of the external air, the liquid will rise in the open limb, and the pressure of the gas will be 1, 2, or more inches, according to the height to which the liquid rises. But if the pressure of the gas be less than that of the atmosphere, the atmospheric pressure, which always acts at the open end of the tube, will prevail, and the liquid will be depressed in the open limb, and rise in the other.

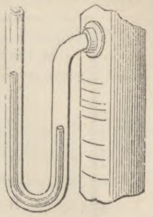

Fig. 16.

The Gas-Meter.

Design of the gasometer.

The gas-meter is a simple but ingenious mechanical contrivance, the design of which is to measure and record the quantity of gas passing through a pipe in any given interval of time. Experience has proved it to be no less advantageous to the consumer than to the manfacturer of gas, by allowing the former to use gas without any unnecessary waste of it, and securing to the latter a fair and regular price for the quantity of it actually consumed.

The wet meter.

There are two forms of meter in actual use, viz., the *wet* and the *dry*. The former, the invention of Mr Clegg, is represented in the following figures. In the sections, figs. 17, 18, *cc* represent the outside case, having the form of a flat cylinder; *a* is a tube which enters at the centre for admitting the gas, and *b*, fig. 17, is another for conveying it off to the burners; *g*, *g* are two pivots, one supported by the tube *a*, and the other by an external water-tight cup, projecting from the outside casing, and in which is contained a toothed wheel *h*, fixed upon the pivot, and connected with a train of wheel-work (not shown in the figure) to register its revolutions. The pivots are fixed to and support a cylindrical drum-shaped vessel *ddd*, having openings *e*, *e*, *e*, *e*, internal partitions *ef*, *ef*, *ef*, *ef*, and a centre piece *ffff*. The machine is filled with water, which is poured in at *h* up to the level of *i*, and gas being admitted under a small pressure at *a*, it enters into the upper part of the centre piece, and forces its way through such of the openings *f* as are from time to time above the surface of the water. By its action upon the partition which curves over the opening *a*, a rotatory motion is communicated to the cylinder; the gas from the opposite chamber being at the same time expelled by one of the openings *e*, and afterwards escaping at *b*, as already mentioned.

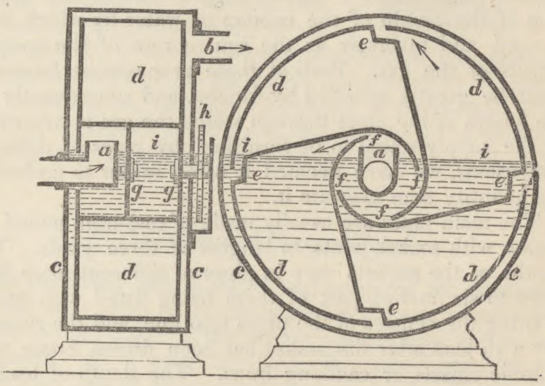

Fig. 17. Fig. 18.

As the quantity of gas which passes through the machine in any given time depends not only upon its internal dimensions and the number of revolutions which it performs, but also upon the level of the surface of the water in which the cylinder revolves, due care must be taken to maintain the water at the same level, for the regular action of the meter. This is easily accomplished, by pouring in water when necessary, till the superfluous quantity is discharged by an orifice properly placed for the purpose.

The dry meter.

One great objection to the wet meter is, that the water is liable to freeze in winter, by which means the supply of gas is stopped: it has been proposed to use a solution of caustic potash or soda instead of water, as being less liable to freeze, and exerting a beneficial action on the gas by removing traces of carbonic acid or sulphide of hydrogen. A second objection is, that if the water level be lowered so that one compartment may at the same time communicate with the central and outer spaces *f f* and *d e*, more gas will pass than can be registered, an effect sometimes produced by the dishonest consumer tilting forward the meter. In the dry meter, as its name implies no liquid is used, and the gas is measured by the number of times that a certain bulk of it will fill a chamber constructed so as to contract and expand for the passage of the gas. These alternate contractions and expansions give motion to certain valves and arms, which, with the aid of a train of wheels, turn the hands of the dials as in the wet meter. The two forms of dry meter which have attracted most attention are Defries's and Croll and Glover's. Defries's meter consists of three measuring chambers separated by leathern partitions partially covered by metal plates, and as they expand by the pressure of the gas they assume the form of a cone on one side or other, the motion of which backwards and forwards drives the measuring machinery, and by an action somewhat similar to that of a three-throw pump, a continuous stream of gas is ejected. This incessant bending of the leather backwards and forwards causes it to wear rapidly, while the efficiency of the meter obviously depends on the soundness of the leather. In Messrs Croll and Glover's meter the leather is applied in perhaps a less objectionable form. This meter consists of two short metal cylinders, each closed at one end; AA, fig. 19, representing one such end attached to a fixed central plate BB, by means of broad bands of leather, which act as hinges, allowing one side to swell out with gas, while the other parts with its gas by being pressed in towards the centre plate. The to-and-fro motion of the discs which close the short cylinders affords means for measuring the gas. Each disc is kept in place by a hinge joint S attached to upright rods, RR′. There are also parallel motions *exy* attached to each disc, and to the top plate of the meter. As the gas passes into each cylinder and distends it, the rods RR′, one on each side, are made to move each through the half of a circle by means of jointed levers S attached to them. At the top of each rod are two arms R*ad*, R′*ad*, fig. 20, each of which partaking of the motion of the rods RR describes alternately the arc of a circle, and a rotatory motion is obtained by means of connecting rods attached to these arms, and also to two other arms *rr* which work two D valves DD, each of which is made to slide backwards and forwards over three apertures, the two outer of which lead to the inside and outside of the cylinders respectively, and the middle aperture to the exit pipe E. It is the function of these valves to regulate the flow of gas into and out of the two chambers of each division of the meter. While the gas is flowing into one cylinder and distending it, the gas on the other side of this cylinder disc is expelled to the exit pipe E; as soon as this is done, the valve is reversed and gas enters on the side of the disc from whence it was last expelled. The process is then repeated by the other disc, and in this way a continuous flow of gas is obtained by means of the two valves DD, which being placed at right angles to the double-cranked shaft, and the two cranks on the shaft being at an angle of 45° to each other, it follows that as one valve closes the other opens, but the closed valve always begins to open before the other is quite shut. In fig. 20, the dotted portion represents one of the short cylinders A′ distended with gas, and the other cylinder A collapsed.

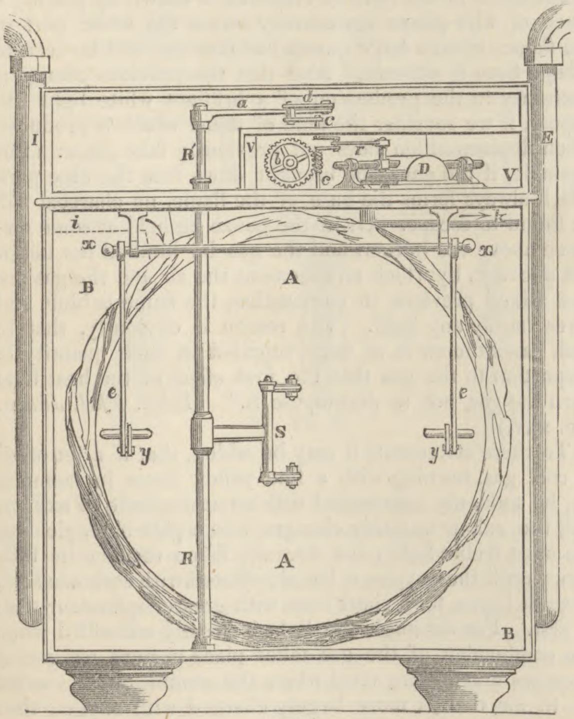

Fig. 19.

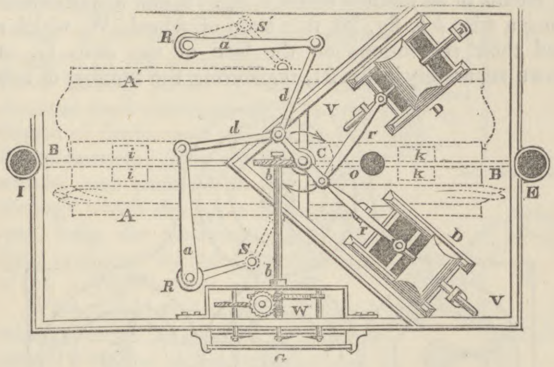

Fig. 20.

We will now trace the course of the gas in its passage through the meter. Suppose a continuous stream of gas under pressure to be passing down the inlet pipe I. On arriving at *i* it meets with a horizontal tube which conducts it by the aperture *o*, fig. 20, in the direction of the arrow into a triangular chamber VV. It then passes down an open slit of one of the valves, which we will call No. 1, and entering one of the cylinders, distends it and forces the gas which was on the outside of the disc to escape through slit No. 2, and so along a tube *k* leading to the exit pipe E. While this action is going on, that is, while the cylinder on one side is being distended, the cylinder on the other side is already full, the gas is shut off from it by the sliding valve D, and is made to pass on the outside, where exerting its pressure on the disc AA, it forces it inwards, and the gas escapes along a short pipe attached to either side of the partition BB into slit No. 2, and so escapes to the exit pipe. The triangular chamber V V has no connection with the cylinders, &c. situated below it except through the tubes already indicated, and the train of wheels W, fig. 20; and the dials are also so boxed in as not to be exposed to the corrosive action of the gas. The rods R′ R pass into this upper compartment through leather washers and a stuffing of wool. The cylinders are inclosed in an oblong box of iron plate or galvanized iron, so as to be completely concealed from view. The pressure to which the gas is subjected in order to force it along the mains is amply sufficient to work this meter. If the gas were subjected to the pressure of only half an inch of water, this quantity multiplied into the area of the disc, which in a ten-light meter is ten inches in diameter, amounts to many pounds.

The circular motion of the double crank is transmitted by means of an endless screw *c*, fig. 19, and a spur-wheel *b* along a wire *b b*, fig. 20, to a train of wheels W, which record their revolutions on the face of the dials G, also shown separately in fig. 21, registering the number of cubic feet of gas consumed, in units, tens, hundreds, thousands, &c. The top circle marks the units, the left hand circle hundreds. The motion of the hand from 0 to 1 shows that 100 cubic feet of gas have passed through the meter, while a whole revolution of this hand registers ten times that quantity, or 1000 cubic feet. The motion of the hand of the centre circle from 0 to 1 indicates 1000 feet, and a whole revolution 10,000 feet. The right hand circle, in a similar manner, indicates in a whole revolution 100,000 feet. In reading off the numbers on the circles, we take the number at which the hand is pointing, or the lower of the two numbers that the hand is between. In fig. 21, beginning with the right-hand dial, the hand is between 9 and 0, showing that nearly a whole revolution has been accomplished; we therefore write down,

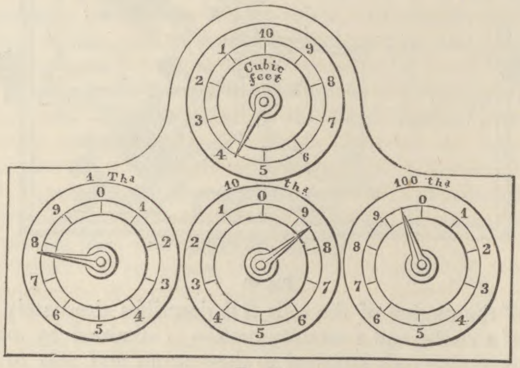

Fig. 21.

90,000 for the right-hand dial,
8,000 for the middle dial,
700 for the left-hand dial.

98,700

If the collector, in taking the register three months before, had recorded the quantity as 73,200, this quantity, deducted from 98,700, gives 25,500 cubic feet as the consumption of gas for three months. The top or units dial is not used in registering, but it serves to indicate to the collector as well as to the consumer that the dial is acting properly, the more rapid motion of the hand facilitating this object.

Burners.

Principles upon which the light yielded by combustion depends.

The most economical mode of consuming gas, so as to obtain from a given volume of it the greatest possible quantity of light, both in degree and duration, is a problem of no less importance than that of the most suitable arrangements for its production and purification. The presence of oxygen, in some form or another, being essentially necessary to produce ordinary combustion, it follows, that from whatever cause that principle may be deficient in quantity, the combustion must be imperfect; and when this is the case, the light yielded by the combustible body is also diminished in a proportional degree. On the other hand, if the quantity of oxygen brought into contact with the combustible body be more than sufficient for its entire combustion, the superfluous quantity of that gas, instead of augmenting the effect, can only lower the temperature, and diminish, it may be presumed, in a corresponding degree, the intensity of the light. This must be the consequence if the brilliancy of the light yielded by a combustible body depends at all upon the temperature to which it is exposed during its combustion; and that this is the case may be inferred from the simple fact of causing the flame of a jet of gas to play, first against a sheet of ice, and then against a bar of red-hot iron, when the difference of the light will be such as to leave no doubt of the influence of temperature upon its intensity. A similar result is obtained by bringing the flames of two separate jets into contact, when an obvious increase of light is perceived. From these simple facts it may be inferred, that though a certain quantity of common air must be brought into contact with the inflamed gas to produce the greatest intensity of light, whatever exceeds that quantity will not only be useless, but, by diminishing the temperature of the flame, must tend to impair the brilliancy of its light.

But although the immediate cause of the light is probably the high temperature to which the carbonaceous portion of the gas is exposed, the condition in which the carbon exists at the time it is so exposed is of the utmost importance to the effect. According to the opinion of Sir Humphry Davy, as adopted by Drs Christison and Turner, "a white light is emitted only by those gases which contain an element of so fixed a nature as not to be volatilizable by the heat caused during the combustion of the gas; and that in coal-gas this fixed element is charcoal, formed by the gas undergoing decomposition before it is burnt. The white light is caused by the charcoal passing into a state, first of ignition, and then of combustion. Consequently no white light can be produced by coal or oil gas without previous decomposition of the gas."

"That the gas undergoes decomposition before it burns, and that the carbonaceous matter is burnt in the white part of the flame in the form of charcoal, is shown by placing a piece of wire-gauze horizontally across the white part of the flame, when a large quantity of charcoal will be seen to escape from it unburnt. And that this previous change is necessary to the production of a brilliant white light will appear, if we consider the kind of flame which is produced when decomposition does not previously take place. For example, if the gauze be brought down into the blue part, which always forms the base of the flame, no charcoal will be found to escape. Or, if the gauze be held at some distance above the burner, and the gas be kindled not below but above it, by which arrangement the air and the gas are well mixed previous to combustion, the flame is blue, and gives hardly any light. The reason is obviously, that in both cases the air is at once supplied in such quantity in proportion to the gas that the first effect of the heat is to burn the gas, not to decompose it." (*Edin. Phil. Journ.* No. xxv.)

Circumstances influencing the intensity of the light.

To these statements it may be added, that if a jet of oil or coal gas, burning with a fine yellow flame in common air, be suddenly surrounded with an atmosphere of oxygen gas, the colour instantly changes into a pale blue, yielding the most feeble light; nor does the flame recover its brilliancy until the oxygen is largely diluted with carbonic acid, when it burns for a short time with greater splendour than at first. For although the light is greatly enfeebled when the combustion of the gas takes place in pure oxygen, it becomes much more vivid when the combustion is carried on in air that is more largely charged with oxygen than common air. Hence the brilliancy of the light appears to depend upon two conditions; 1*st*, the perfect combustion of a portion of the gas in an undecomposed state; 2*dly*, the temperature produced by that combustion upon the residual part in a decomposed state. When a large portion of the gas is consumed in the first condition, the temperature is higher; but the undecomposed part is then too small in quantity to yield an intense light, in consequence of the attenuated state of the carbon; and, on the other hand, when a small portion of the gas is consumed in the undecomposed state, the temperature produced is too feeble to raise the temperature of the now partially decomposed part to a sufficient pitch for the full ignition of the carbon.

General principles to be observed in the construction of burners.

The conditions which thus seem to be necessary for obtaining the greatest portion of light from the combustion of a given quantity of gas, while they are perfectly consistent with the most anomalous facts presented by that process, so they appear to afford the only sure principles upon which we can proceed in the construction of gas-burners. One of the most obvious conclusions deducible from these principles is, that whatever be the form of the gas-burner its construction should be such that while it admits as much air as is necessary for the perfect combustion of the gas, it should never admit more than is barely sufficient for that purpose.

Experiments of Drs Christison and Turner.

According to the experiments of Drs Christison and Turner, the diameter best fitted for single-jet burners appears to be about one twenty-eighth of an inch for coal-gas, and one forty-fifth for oil-gas. As these dimensions, however, must vary with the quality of the gas, we consider one thirty-sixth of an inch to be more applicable to the gas obtained from cannel coal, if its specific gravity be not less than ·65. Every form of burner composed of separate jets, in which the gas is made to issue in a horizontal or oblique direction, gives a consumption which increases in a much faster ratio than the light which it yields; and consequently, however beautiful such burners may be in appearance, they are far from being economical.

Forms of burner.

One of the most useful forms of a burner with single jets, is where there are two holes, and their directions are so inclined as to cause the streams of issuing gas to cross, and exhibit during their combustion a broad continuous flame. This burner, which is termed a *swallow-tail*, is well adapted for street-lights, as it gives a powerful light, and consumes a small quantity of gas. When the gas is emitted by a narrow slit at the top of the burner, the burner receives the name of a *bat-wing*. Specimens of common gas flames are represented in figs. 22, 23, 24.

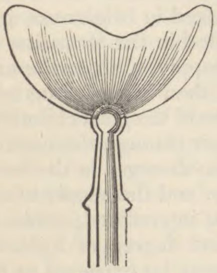

Fig. 22.

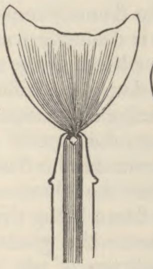

Fig. 23.

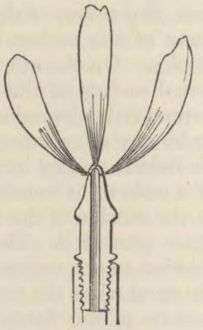

Fig. 24.

Argand burner.

But of all the forms of the burner, that upon the Argand principle, in which the holes are arranged in a circle, *d*, fig. 25, so as to allow the air to have access to the flame internally as well as externally, is the most economical, and the best calculated to secure the complete combustion of the gas. The diameter of the holes should, in this burner, be about the fortieth part of an inch for coal-gas of an ordinary good quality, and the distance between them should be such as to allow the separate flame of the different jets to unite together and form a continuous hollow cylinder of light. In fig. 25, *a* is the pipe which supplies the gas, and *b b* the channel up which it passes to the holes shown in the lower figure.

The construction of burners, and the most economical mode of consuming gas, having been examined with much philosophical precision by Drs Christison and Turner, we shall extract from their elaborate dissertation on the subject the most valuable and important conclusions which they have deduced from their experiments; and this we do with greater confidence, because the results they obtained coincide very exactly with those which the writer of this article procured when engaged in the same inquiry. The three leading points to which they directed their attention were, 1*st*, the length of flame most suitable for different burners; 2*dly*, the form, magnitude, and position of the orifices through which the gas is discharged; and, 3*dly*, the modifications of the light produced by the glass chimney of the Argand burner.

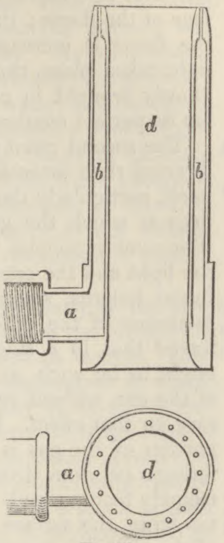

Fig. 25.

Length of flame.

With regard to the length of flame which afforded the greatest light compared with the expenditure of gas, they found that, in the case of the jet, the best length for coal-gas was about five inches, and for oil-gas about four inches. When the flame was kept shorter, the quantity of gas consumed was greater in comparison of the light which it yielded; but no advantage was gained by increasing the length beyond that mentioned as the most suitable for each gas; the combustion becoming less perfect, and beginning to be accompanied with the escape of the carbon in the form of smoke. Thus they found that, in the case of coal-gas having the specific gravity ·602, while the lights emitted from a two-inch and a five-inch flame were as 556 to 1978, the corresponding expenditures were to each other as 605 to 1437. But the light, in an economical point of view, must be estimated inversely as the quantity of gas from which it is obtained; and hence the ratio of the lights, in reference to the expenditure, was as $\frac{556}{605}$ to $\frac{1978}{1437}$, being as 100 to 150.

In the case of Argand burners, the augmentation of the light in a ratio greater than the expenditure was exemplified in a still more remarkable degree. Thus the following results were obtained with coal-gas of the specific gravity ·605, by elevating the flame of a five-holed burner, successively from half an inch to five inches.

Length of Flame.	Half-Inch.	One-Inch.	Two-Inch.	Three-Inch.	Four-Inch.	Five-Inch.
Light	18·4	92·5	259·9	308·9	332·4	425·7
Expenditure.........	83·7	148	203·3	241·4	265·7	318·1
Ratio of light to expenditure.....	100	282	560	582	582	604

Hence the light is increased about six times for the same expenditure by raising the flame from half an inch to three or four inches; but very little is gained by any additional increase of the flame beyond that length, in the description of burners with which the experiments were made.

These facts receive a satisfactory explanation from the general principles which we have already laid down with respect to the combustion of the luminiferous gases. When the flame is short, the supply of oxygen for the combustion is too great; almost the whole of the gas is thus consumed before any portion of it can undergo the decomposition which is necessary for the evolution of light; while the temperature of the flame being reduced by the superfluous air which brushes along its surface, the intensity of ignition, and with it the splendour of the light, is proportionally diminished. This explanation is well illustrated by partially shutting the central part of the burner, and thus interrupting the supply of air to the internal surface of the flame; the moment this is done, the length of the flame is increased, and a visible improvement of the light takes place, thus indicating that more air was previously brought in contact with the gas than was requisite for its perfect combustion.

Magnitude and position of the orifices.

The second point to which Drs Christison and Turner directed their attention was the construction of the burner itself, particularly the magnitude and position of the orifices at which the gas is emitted during its combustion. The same principles which explained the relation between the light and the expenditure in the case of flames of different lengths, suggested the rule for regulating the dimensions of the orifices; and accordingly they justly inferred that, in a single jet, the diameter of the aperture ought to be such as to ensure the complete combustion of the gas, without rendering it more vivid than is necessary for that effect. If the orifice be too small, the greater portion of the gas is liable to be consumed without suffering a previous decomposition, and thus the light is extremely feeble; and, on the other hand, if the orifice be too large, the surface of the flame exposed to the action of the air being too small in comparison of the discharge of gas, the combustion is imperfect, and the carbon, after being separated from the hydrogen, either burns at a low temperature with a dusky flame, or, what is still worse, a large portion of it passes off in the state of smoke. In conformity with these views, they recommend, as we have already stated, a twenty-eighth of an inch for coal-gas, and a forty-fifth for oil-gas, as the most suitable dimensions for single jets. They acknowledge, however, that their experiments with coal-gas were too limited to justify them in using very confident language on the subject; and we have therefore the less hesitation in stating that we consider an orifice varying in diameter from a thirty-second to a thirty-sixth of an inch as better adapted to coal-gas of a specific gravity between ·62 and ·70.

Orifices of Argand burners.

In Argand burners the diameter of the orifices ought to be a little smaller. Drs Christison and Turner state that the diameter which appeared to answer best for coal-gas of the specific gravity ·6, when the holes are ten in a circle of three-tenths of an inch radius, was a thirty-second of an inch. We consider this, however, to be too great for coal-gas of a better quality, and would recommend, in preference, apertures varying in diameter from a thirty-sixth to a fortieth of an inch.

Distance of jet-holes.

The distance between the jet-holes of Argand burners is a matter of no less importance than the diameter of the orifices, and must be regulated by the same principles. When they are so far asunder that the flames of the separate jets do not coalesce, no advantage is derived from the Argand form; but when they unite, and compose a uniform and unbroken surface of flame, the light is considerably greater, compared with the expenditure of gas, than is obtained from detached jets. In order to determine the most suitable distance at which the orifices of Argand burners should be placed, Drs Christison and Turner employed burners six-tenths of an inch in diameter, which they caused to be drilled with eight, ten, fifteen, twenty, and twenty-five holes, a fiftieth of an inch in diameter; and having determined with each of these burners the light and expenditure in the case of oil-gas, they obtained the following results:—

Burners.	VIII.	X.	XV.	XX.	XXV.
Light	360	360	391	409	382
Expenditure	367	318	296	289	275
Ratio of light to expenditure	98	113	132	141	139

As the standard of comparison was a single jet, burning with a four-inch flame, the ratio of the light yielded by which to the expenditure was expressed by 100, it was inferred that no advantage is gained by giving the jets the Argand arrangement with a burner of the dimensions above mentioned if the holes are only eight in number; and that the gain does not increase after the number reaches to twenty. In the former case the distance of the holes must have been ·2356 inch, or nearly one-fourth of an inch, and, in the latter, ·0945; so that the most advantageous distance for jet-holes of a fiftieth of an inch in diameter would seem to be about $\frac{9}{100}$ths of an inch. For coal-gas burners, however, the distance between the jet-holes ought to be increased in a ratio varying inversely with the quality of the gas, or directly as the diameters of the orifices themselves. Hence, if the coal-gas were of an ordinary quality, the jet-holes should not be less than one-eighth nor more than one-sixth of an inch from each other.

Diameter of circle of holes.

The distance between the orifices being once assumed, serves to determine the diameter of the circle of holes. Thus, in a burner of eighteen holes, each a seventh of an inch asunder, the circumference ought to be $18 \times \frac{1}{7} =$ 2·57 inches, and consequently the diameter of the circle of holes should be $\frac{2{\cdot}57}{3{\cdot}1416} = {\cdot}818$ inch. If the breadth of the rim be supposed to be a tenth of an inch, and perhaps it ought not to exceed that quantity, it may be proper, in the case of the larger burners, to contract the lower part of the central air-hole, on account of the supply of air to the inside surface of the flame increasing in a faster ratio than the number of jets.

Glass chimney.

The only remaining point to be considered with respect to the burner is the glass chimney, which serves at once to protect the flame from irregular currents of air, and to convey to the gas a due supply of it during combustion. When the interval between the chimney and the external part of the flame is too great, the tendency of the air to flow through the air-hole is diminished, and the flame contracts towards the top, where it yields a dusky light, and indicates a disposition to smoke. The diameter of the chimney should therefore be reduced until it is perceived that the upper part of the flame is enlarged, and acquires the same diameter as the lower part. When this is the case, the colour of the flame is improved in brightness, and none of the carbon is uselessly wasted in the formation of smoke. On the other hand, if the supply of air to the external surface of the flame be diminished beyond a certain extent, either by reducing the diameter of the glass chimney, or by any other means, the flux of air through the central air-hole is unduly increased, the flame diverges in the form of a tulip till it touches the chimney, and the supply of air to the outside of the flame being thus interrupted, smoke is again produced. Hence the greatest degree of light, in relation to the expenditure of gas, may be expected to be obtained when the supply of air to the external and internal surface of the flame is so adjusted by the diameter of the chimney that the flame is perfectly cylindrical, neither burning with too much vivacity, nor showing any tendency to smoke. The length of the glass chimney is of much less importance than its diameter, and may vary from five to six inches.

A cylindrical chimney, however, is the least advantageous form that can be adopted. If the chimney be tall and narrow, and contracted towards the top, as in *a*, fig. 26, or suddenly contracted near the bottom, as in *b*, the draught is increased and the light improved. It is also useful to contract the

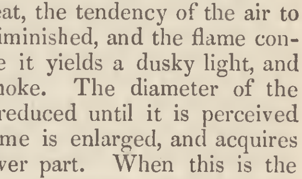

Fig. 26.

diameter of the glass chimney about a couple of inches above the burner, as at *c*, so as to form a shoulder a few lines in width, the effect of which is to change the direction of the draught, and project it on the flame at a certain angle.

Bude light.

In the Bude light proposed by Gurney, oxygen gas instead of air was passed through the flame, the effect of which was greatly to increase its brilliancy. In the Bude light as now constructed, there are two, three, or more concentric burners with chimneys supplied with common air, and a dioptric apparatus.

Ventilation of burners.

Attempts have been made of late years to ventilate gas burners so as to get rid of the injurious products of combustion. One part by weight of good coal-gas produces nearly three parts by weight of carbonic acid, which produces many distressing symptoms when breathed with the air of the room. Sulphurous acid, and other compounds which are not entirely removed in the purification of the gas, form deleterious products during the combustion of the gas. The sulphurous acid forms sulphuric acid, which exerts a corrosive action on the walls and furniture, books, pictures, &c., while the hydrogen of the gas produces vapour of water which serves as a vehicle for some of the other products. To get rid of these noxious fumes a bell-shaped vessel is sometimes suspended over the chimney, and is connected with a tube leading into the open air. Unless this tube be judiciously arranged the condensed water of the gas may accumulate in it, and cause inconvenience. By a contrivance of Dr Faraday, a copper tube of about the same diameter as the flame is conducted from its summit out of the apartment; the heat of this tube establishes a rapid current, which serves to convey away the products. The same distinguished chemist invented another contrivance, by which the ventilating current is made to descend between two concentric glass chimneys of different heights, the outer one being the taller, and this is covered with a disc of talc. When the current reaches the bottom of the space between the two glasses, it is conveyed away by a ventilating tube which bends upwards. The descending current is first established by applying heat to the bend of the ventilating tube where it begins to ascend; when this current is established the gas is lighted, and the plate of talc is put on: the products of combustion are conveyed into a box, from which proceeds a pipe for conveying the vapours outside. A globe of ground glass open only at the bottom is placed over the lamp. The accumulation of condensed water in different parts of this apparatus is said to have greatly interfered with its successful action.

Ventilation by means of gas.

Mr R. Brown of Manchester has a contrivance for ventilating by means of gas. Through an opening in the ceiling a wide tube is passed, one end of which conveys the foul air outside, and the other projects a little below the level of the ceiling. The gas pipe enters on one side, and is bent so as to hang perpendicularly in the centre of the tube, and has an annular burner at the lower extremity, surrounded by a glass chimney, which is supported on the top on a metal cone piece, secured to the lower extremity of the tube by screws. This arrangement is surrounded by a hemispherical glass shade with its mouth uppermost, and a few inches below the level of the ceiling. The air of the apartment passes off in the strong draught occasioned by the burner, and a fresh supply of air is admitted at the lower part of the room.

Oil-Gas, Resin-Gas, and Water-Gas.

Composition of oil.

When tallow or oleaginous matter of any kind is raised to a certain temperature, it is resolved into various gases. of which the compounds of carbon and hydrogen, viz. olefiant gas or bicarburetted hydrogen, and light carburetted hydrogen, are the principal, both in point of quantity and quality, for the purposes ef illumination. As oil contains in its composition a portion of oxygen, existing most probably in union with hydrogen in the state of water, that substance also yields, during its destructive distillation, a considerable quantity of carbonic oxide, as well as traces of carbonic acid, hydrogen, and even nitrogen. With these products, all of which are of a determinate character, is found in greater or lesser abundance a quantity of a very inflammable vapour,[1] which seems to be a compound of carbon and hydrogen.

Variable nature of oil-gas.

Oil-gas owes its illuminating power chiefly to the proportion of olefiant gas which it contains, and the oleaginous vapour which is diffused through it; and as both of these ingredients vary in quantity with the temperature at which the decomposition is effected, the quality of oil-gas is extremely fluctuating. When the temperature is too high, a portion of the olefiant gas and oleaginous vapour is resolved, by the deposition of carbon, into light carburetted hydrogen; and though the quantity of gas from a given portion of oil is thus increased, the quality of it is diminished in a still higher ratio. On the other hand, if the temperature be rather too low, a larger quantity of olefiant gas, mixed with a greater proportion of oleaginous vapour, is obtained; but as the latter is gradually and rapidly condensed when the gas is allowed to stand over water, the higher illuminating power of this richer gas is more than counterbalanced by the deficiency in its quantity, and the deterioration to which it is liable by keeping.

Experiments by Dr Henry.

We are indebted to Dr Henry of Manchester for the first analysis of the aëriform compounds obtained by the decomposition of oil by heat; and though his elaborate researches can scarcely be said to have led to the determination of the precise products of that decomposition, they furnish data from which their true nature may be inferred, with a probability nearly as great as that which belongs to the results of direct experiment. The principal difficulty of the analysis consists in determining the condition in which the elementary principles of carbon and hydrogen exist in union with each other, and reconciling the various suppositions that may be made respecting the compounds thus formed, with the specific gravity which belongs to the original gas, supposed to be produced by their mixture.

The results of Dr Henry's first experiments were published in 1805; but it was not till about ten years after that period that an apparatus for decomposing oil, on a large scale for economical purposes, was constructed. In 1815 a patent was obtained by Mr Taylor, in which he was afterwards joined by Mr Martineau, for producing gas from oil, by means of an apparatus which was employed with little variation in all the oil-gas establishments which were subsequently formed in various parts of the country. The general arrangements adopted in that apparatus will be readily understood from figs. 27, 28, and 29.

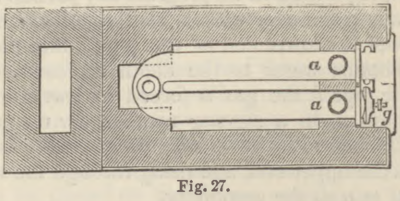

Fig. 27.

The retort *aa* has the form of a horse-shoe, being recurved and furnished with two mouth-pieces. The grate of the furnace is represented by *b*. The oil, which is contained in the cistern *c*, is conveyed by means of a tube, furnished with a stop-cock for regulating the discharge, and allowed to drop into the retort upon fragments of brick or coke heated to redness, to promote the decomposition. The gas, after its production, ascends from tne retort, at the opposite limb through the upright pipe *ff*, by which it is conveyed into a close vessel *hh*, which is surrounded with cold water in the cistern *ii*. From the bottom of the vessel *hh*, a worm or spiral tube *kk* ascends, and after a few convolutions around *hh*, terminates in the pipe *l*, which descends into the air-tight chest *mm*. The gas, leaving the vessel *hh*, is conducted by the spiral tube *kk*, depositing in its progress any portion of the oil that may have come over with it in a volatilized state, and escapes from the lower end of the pipe *l*, into the chest *mm*, which contains water to the depth represented. After quitting the pipe *l*, the gas is forced to traverse the inclined partition *n*, in a zig-zag manner, by means of diagonal ribs attached to its lower side, till gradually ascending, it escapes at the upper end, and rising through the water, finally passes off at *g* to the gasometer.

---

[1] The oleaginous vapour alluded to consists, according to the experiments of Mr Faraday, of two distinct compounds of carbon and hydrogen. One of these he terms *bicarburet of hydrogen*, which, by his analysis, is composed of six proportions of carbon and three of hydrogen. The other compound, to which Dr Thomson has given the name of *quadro-carburetted hydrogen*, consists of four proportions of carbon and four proportions of hydrogen, existing in a different state of aggregation from that in which they exist in olefiant gas, the elementary constituents of which are in the same proportion.

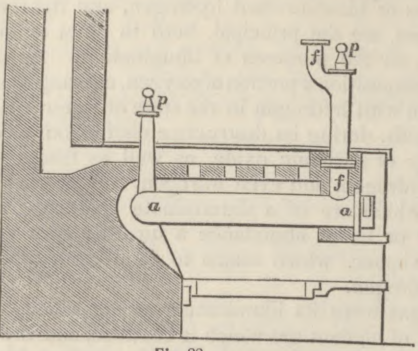

Fig. 28.

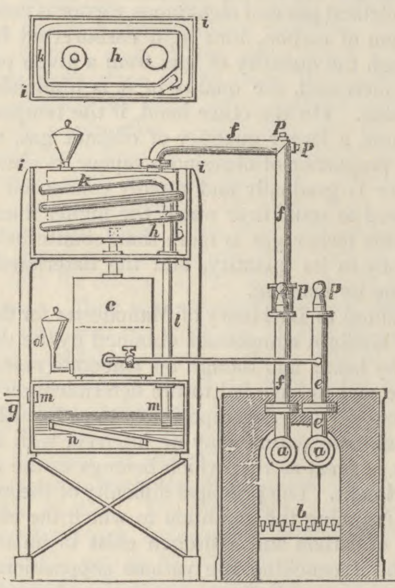

Fig. 29.

Loss incurred by converting oil into gas.

Oil being decomposed at a loss of nearly fifty per cent., the conversion of it into gas, after a protracted but ineffectual competition with coal, was gradually abandoned on the large scale, even in those places where, from the interest they had in the whale-fisheries, there was the strongest inducement to foster the prejudices which prevailed for some time against the use of coal-gas. The exaggerated advantages which it was pretended would be derived from compressing oil-gas and thus rendering it portable, served to prolong the delusions on the subject; nor were these delusions fully removed until a demonstration was given of the failure of the scheme, in the decay of the costly edifices and expensive apparatus which had been constructed for carrying it into effect. The late Professor Daniell of King's College, London, also contrived an ingenious form of apparatus for making gas from resin; but the plan did not succeed on account of the impossibility of competing with the coal-gas works.

Water-gas.

Of late years a new process of gas-making has been much discussed, and has formed the subject of a variety of patents. It is known as the *hydrocarbon process of gas-making*, or more briefly *water-gas*. The principle of the manufacture is to pass steam over red-hot coke, by which it is resolved into hydrogen and carbonic oxide, and then to supply these inflammable gases with the carbon required for their illuminating power, by passing them through a retort in which oil, resin, tar, naphtha, cannel coal, or some other carbonaceous substance, is undergoing decomposition by heat. The process does not appear to have been successful with resin, but better results seem to have been attained with cannel coal.

Methods for determining the Illuminating Power of the Gases.

Having described the various manipulations by which gas is prepared, both from coal and oil, we now proceed to explain the methods which have been adopted for determining their respective illuminating powers; it being by these methods that we acquire a knowledge of one of the most important tests by which the comparative value of the gases can be ascertained.

Determination of the intensity of light by the method of shadows.

The first and most obvious of these tests is to determine the intensity of the light which the gases are capable of diffusing during their combustion, upon a white and smooth surface directly exposed to its emanations. The determination of that intensity is obtained with a considerable degree of accuracy, not by a direct comparison of the degree of illumination shed on two separate surfaces, but by means of a contrivance, first proposed by Count Rumford, which allows the illuminated surfaces to be contrasted with each other on the same ground, and so closely adjoining that the eye can readily detect a slight difference between them. This contrivance is as follows: Let A and B, fig. 30, be two luminous objects; EF a smooth and white surface, having the same inclination to the rays of light emitted by A and B; and CD an opaque cylindrical rod parallel to the surface EF; then it is evident that *aa* and *bb* will be the shadows of CD, in reference to the lights A and B. But the shadow *aa* being illuminated by the light B, and the shadow *bb* by the light A, it follows that if these shadows be perfectly the same in point of intensity of shade, the light yielded by A and B must be the same in degree. If the shadows, however, be different, one of the lights must be removed either further from EF or brought nearer to it, until the shades seem to be exactly alike, when the light shed upon EF by A and B must, in point of intensity, be, as before, the same. But the intensity of light, like that of other emanations proceeding in straight lines from a central point, being inversely as the square of the distance, the relative degrees of light emitted by A and B must, in con-

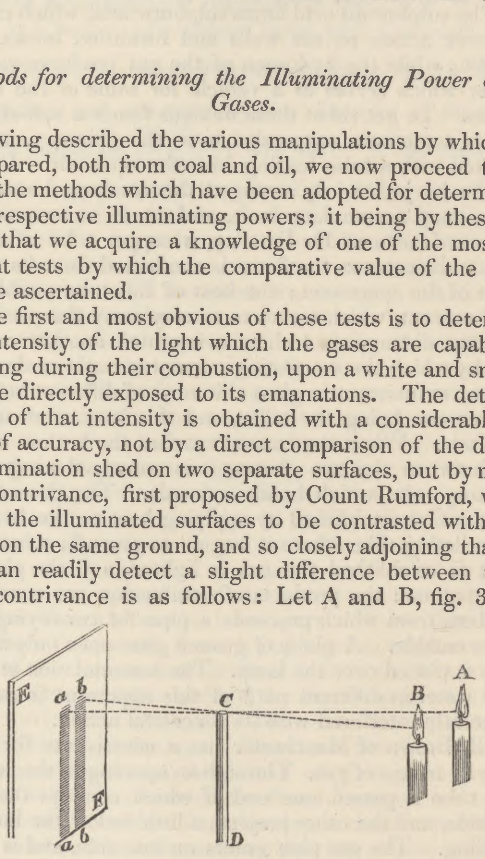

Fig. 30.

formity with that principle, be proportional to the squares of their respective distances from the surface on which the shadows are projected. Thus, if the light A were at the distance of fifteen feet, and the light B at the distance of twenty-five feet, their relative illuminating powers would be as the square of fifteen to the square of twenty-five; that is, as 225 to 625, or as 9 to 25. As the quantity of gas consumed in the same time to yield the supposed lights might be different, it is evident that a correct estimate of the absolute value of the gases for the purpose of illumination would not be duly determined unless that circumstance were also taken into account. But the economical value of the gases, yielding equal degrees of light, being inversely as the quantities consumed, it follows that that value will be directly as the squares of the distances at which the shadows are the same, and inversely as the rate of consumption. Thus, if we now suppose that the gas yielding the light A consumed three cubic feet in the same time that the gas yielding the light B consumed five cubic feet, the value of the former would be to that of the latter as $\frac{9}{3}$ is to $\frac{25}{5}$, or as three to five. In obtaining the necessary data for determining the ratio of the lights, it may be proper to add that the screen on which the shadows are projected should be guarded with the utmost care from all extraneous light. If it be desired to contrast the illuminating power of a gas-light with that of a candle, the comparison is easily made. If, for example, the gas-light give a shadow equal to that of a candle placed at one-third the distance, the light of the gas is equal to the light of nine candles. If the candle be placed at one-fourth the distance of the gas-light, the latter is equal to sixteen candles, and so on.

Bunsen's photometer.

Professor Bunsen of Marburg has contrived a photometer which is now in common use in gas-works. The principle of this instrument is not the comparison by shadows, which forms a delicate experiment, but a comparison of light transmitted through a translucent surface with light reflected from an opaque surface. For this purpose a disc of paper, TO, fig. 31, is placed between the two lights to be compared; an annular portion of this paper T is made translucent by means of melted spermaceti, or that substance dissolved in oil of naphtha, while a central disc of the paper O being left untouched by the composition, remains opaque. Fine cream-coloured letter-paper answers the purpose very well, and the central opaque disc may be about the size of half-a-crown. Now it is evident that the translucent ring will be illuminated by a light behind the disc, while the opaque portion is illuminated by a light in front. The frame on which the disc is mounted is moved backwards and forwards on a graduated bar BB between the two lights until the transmitted and reflected lights appear of the same intensity. The pointer P then shows the division over which the disc stands. Under such circumstances, the lights are to each other in the ratio of the squares of their distance from the disc. See PHOTOMETER.

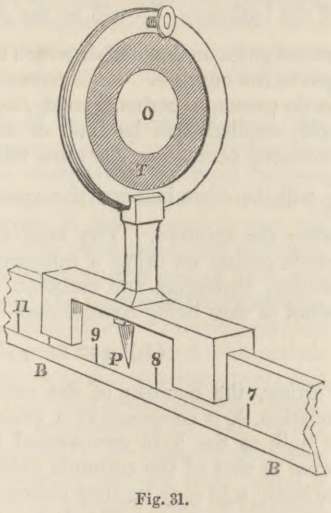

Fig. 31.

Application of chlorine to determine the quality of gas.

The determination of the intensity of light by the above simple means is capable, under careful management, of all the precision which the nature of the problem requires; it is even preferred by engineers to the more elaborate method of chemical analysis. The latter method has for its object to ascertain the relative value of the gases used for illumination, by finding the quantity of olefiant gas which they contain under equal volumes; it being assumed that the illuminating power of the compound combustible gases derived from the decomposition of oil and pit-coal is directly proportional to the quantity of that gas existing in their constitution. Though that supposition is by no means a matter of certainty, or even of probability, we shall nevertheless briefly explain the mode of analysis which has been recommended. According to the experiments of Dr Henry, chlorine has no action upon any of the gases obtained from oil or coal when the influence of light is carefully excluded, with the exception of olefiant gas; and as chlorine and olefiant gas unite together in equal volumes, this property affords an easy mode of determining the quantity of the latter which may exist in any compound gas of which it forms a constituent part. All that is required for the purpose is to add somewhat more chlorine than is absolutely necessary for uniting with the olefiant gas, and to allow the mixture to remain about fifteen minutes completely excluded from light. The extent of the absorption being thus observed, half the quantity of the gas which has disappeared of the whole mixture will be olefiant gas. Thus, if twenty parts of chlorine by measure were added to twenty-five of coal-gas, and if the mixture, after being allowed to remain a sufficient length of time in the dark, were found to occupy thirty-six measures, the absorption would be nine measures, and consequently the coal-gas must have contained four and a half measures of olefiant gas, or eighteen per cent. The quantity per cent. of olefiant gas is determined without calculation, by adding to fifty measures of the gas to be analysed an equal volume of chlorine; when the diminution of volume, in the graduated jar, is the quantity which the gas contains per cent. of olefiant gas. Dr Fyfe states that the illuminating power of the different specimens of oil and coal gas which he subjected to this test bore a pretty exact ratio to the quantity of olefiant gas which they contained. One great advantage to be derived from this method of testing the quality of any species of carburetted hydrogen containing olefiant gas in its composition, is, that it admits of a comparison being made between gases in different places and at different times, without the necessity of transporting them to a distance, and making a simultaneous examination of their illuminating properties.

The bromine test.

Of late years, bromine has been substituted for chlorine in the above analysis. The gas is passed up into a eudiometer tube, and the carbonic acid is removed by means of caustic potash: a small portion of bromine is dropped in and shaken in contact with the gas. Potash is again added to remove the bromine vapours, and the absorption is then noted. It is stated that some of the highly illuminating cannel-coal gases are condensed by this process as much as 12 or 14 per cent.; while some of the poorer gases not more than 4 or 5 per cent.

Specific gravity of oil and coal gas an imperfect test of their quality.

The specific gravity of oil and coal gas, and the quantity of oxygen which they require for their perfect combustion, have also been proposed as means of ascertaining their illuminating powers. The latter, however, even if it were a correct test, is determined with considerable difficulty; and that little reliance can be placed on the former may be inferred from the fact that some of the gases which are component parts of oil and coal gas have a great specific gravity without possessing any illuminating power. This will readily be perceived from the subjoined table.

Gases.	Specific Gravity.	Quantity of Oxygen for 100 volumes.
Olefiant gas	·970	300
Carburetted hydrogen	.556	300
Hydrogen	·069	50
Carbonic oxide	·972	50
Carbonic acid	1·538	None.

Of these gases, carbonic oxide and carbonic acid possess the greatest specific gravity; while the latter is not only destitute of illuminating property, but calculated, as we shall afterwards show, to deteriorate to a great extent the quality of the luminiferous gases with which it may happen to be mixed.

Analysis of coal-gas.

There are cases, however, in which it is necessary to determine accurately the composition of a sample of coal-gas, and the following is the now generally adopted method of conducting the analysis.[1] The ingredients or impurities which may be present in the gas are—1. Common hydrogen; 2. olefiant gas and other hydrocarbons; 3. light carburetted hydrogen; 4. carbonic oxide; 5. carbonic acid; 6. sulphuretted hydrogen; 7. ammonia; 8. oxygen and nitrogen derived from the atmosphere. A qualitative examination is made thus—the proportion of ammonia and of sulphuretted hydrogen is usually very minute, and in most cases these gases must be sought for by placing the tests for their presence for some time in a current of the gas. In searching for ammonia a piece of moistened litmus paper feebly reddened is placed for a minute in a jet of the issuing gas. If the blue colour be restored, ammonia is present. Paper soaked in a solution of acetate of lead may be subjected to a similar trial. If it turn brown, sulphuretted hydrogen is present. The presence of oxygen is detected by admitting a bubble of the deutoxide of nitrogen into a tube filled with the gas under trial, and looking through the tube obliquely upon a sheet of white paper; very small traces of oxygen may thus be detected by the red tinge produced, owing to the formation of peroxide of nitrogen. The presence of carbonic acid may be readily detected by throwing up a little lime water, or solution of sub-acetate of lead, into the gas whilst standing in a tube over mercury. The existence of the other gases may be assumed, as they are certain to be present in greater or less quantity. The sulphuretted hydrogen and ammonia being neglected, and supposing that oxygen and carbonic acid are found to be present, seven different gases are therefore supposed to exist in the mixture. The following method may be adopted for their quantitative determination:—1. *Oxygen.*—A volume of the gas is confined over mercury, and its bulk is measured with due attention to temperature and pressure. A piece of moist phosphorus, which has been melted upon the end of a long platinum wire to serve as a handle, is introduced from below through the mercury into the tube. After twenty-four hours the phosphorus is withdrawn, when the amount of absorption indicates the proportion of oxygen which was present. 2. *Carbonic Acid.*—This gas is determined in a similar manner, substituting a ball of caustic potash for the phosphorus; the second diminution in bulk shows the proportion of carbonic acid. 3. *Olefiant Gas and Heavy Hydrocarbons.*—These gases are absorbed by introducing a third ball, consisting of porous coke, moistened with fuming sulphuric acid. It is necessary, however, before reading off the volume of the gas, to introduce a ball of potash a second time, to withdraw the vapour of anhydrous sulphuric acid, which possesses sufficient volatility to introduce a serious error by dilating the bulk of the gas, unless it be completely removed. The total amount of absorption will indicate the proportion of olefiant gas, together with the vapours of condensible hydrocarbons. 4. *Carbonic Oxide.*—The separation of carbonic oxide from the other gases is not easily done with accuracy. The gas may be divided into two portions, one of which is to be carefully measured as it stands over mercury, and a small quantity of a solution of subchloride of copper in hydrochloric acid is to be added, and the mixture briskly agitated: the gas is then transferred to a second graduated tube, also standing over mercury, and a ball of potash is introduced for the purpose of absorbing the vapours of hydrochloric acid with which the gas is saturated; the bulk of the gas may then be read off, and the volume of carbonic acid may be known by the loss in bulk. 5. *Nitrogen, Carburetted Hydrogen, and Hydrogen.*—In determining the proportion of these gases, that of the carbonic oxide may also be ascertained, for which purpose a portion of coal-gas, in which the carbonic oxide is still present, is transferred to a siphon-eudiometer, and its bulk is measured: it is then mixed with twice its volume of oxygen, and the bulk of the mixed gases is again measured: the mixture is then exploded by means of the electric spark, and the bulk is a third time measured: call this diminution in bulk a, next inject a small quantity of a strong solution of potash, and the resulting condensation due to the absorption of carbonic acid may be called b; the remaining gases, c, consist of oxygen in excess and nitrogen; the quantity of oxygen in excess is ascertained by mixing the residual gas with twice its bulk of pure hydrogen, and a second time causing the electric spark to pass; one-third of the condensation observed will be due to the excess of oxygen; on deducting this excess from the residue c, the difference gives the quantity of nitrogen. The difference between the amount of the oxygen thus found to be in excess, and that originally introduced, will of course represent the quantity of oxygen consumed; call this d. We have now all the data for calculating the proportion of carburetted hydrogen, of hydrogen, and of carbonic oxide, which are present in the mixture. Let x represent the quantity of light carburetted hydrogen; this gas requires twice its own volume of oxygen for complete combustion, and furnishes its own volume of carbonic acid, which requires an equal volume of oxygen for its formation, or half the amount consumed; the other half of the oxygen being required by the hydrogen, which condenses in the form of water, $2\,x$ will be the diminution in bulk of oxygen which occurs on detonation. Again, when hydrogen is converted into water, it requires half its bulk of oxygen, and both are condensed entirely. If y represent the bulk of the hydrogen, $\frac{3\,y}{2}$ will be the diminution in bulk of the mixed gases on detonation, which is occasioned by the hydrogen in the mixture. Let z represent the volume of carbonic oxide present; carbonic oxide, for conversion into carbonic acid, requires half its bulk of oxygen, the carbonic acid produced occupying the same bulk as the carbonic oxide. $\frac{z}{2}$ will therefore indicate the condensation which occurs on firing the mixture. The total condensation in bulk (a) which occurs on firing a mixture of light carburetted hydrogen, hydrogen, and carbonic oxide, will consequently admit of thus being represented—

$$(1.)\ a = 2x + \frac{3y}{2} + \frac{z}{2}.$$

Further, the quantity of the carbonic acid formed by detonation, b, is composed of a volume of carbonic acid equal in bulk to the light carburetted hydrogen, and a volume equal to that of the carbonic oxide, so that the quantity of carbonic acid may be thus indicated:—

$$(2.)\ b = x + z.$$

And lastly, the oxygen consumed, d, will be composed of the following quantities:—Light carburetted hydrogen, twice its bulk, $2\,x$; hydrogen, half its bulk, $\frac{y}{2}$; carbonic oxide, half its bulk, $\frac{z}{2}$; or the total quantity of oxygen consumed will be the following:—

$$(3.)\ c = 2\,x + \frac{y}{2} + \frac{z}{2}.$$

---

[1] Abridged from *Elements of Chemistry*, by Professor Miller, of King's College, London.

From these three equations the values of x, y, z, are determined:—

$$x = c - \frac{a+b}{3}$$

$$y = a - c$$

$$z = \frac{a+4b}{3} - c.$$

Hints respecting the Improvement of Coal-Gas.

Of all the combustible bodies having an elementary character, carbon and hydrogen are not only the most widely and copiously diffused throughout the three kingdoms of nature, but best adapted for the evolution of light during their combustion. It is only, however, when they are united together in due proportion that they answer the purpose most effectually; and, indeed, in a separate state their illuminating powers are so feeble, that even when their combustion is accelerated and rendered more perfect by the presence of oxygen, the light which they yield is yet unfit for many of the useful ends to which light is subservient. The substances in which carbon and hydrogen are united in the best proportion for the production of light are pit-coal in the mineral kingdom, and oils and fatty matter in the animal and vegetable.

The great abundance of coal, and the comparative cheapness at which it can be obtained, give it a decided advantage in point of economy over oleaginous matter, whether of animal or vegetable origin; while the processes of decomposing it, with the view of converting it into a volatile and elastic product, have been so much improved as to render the gas which it yields equally fit for the purpose of illumination with the more costly gases obtained from the oils.

The gas produced by the decomposition of coal and oleaginous matter at a high temperature is a compound of carbon and hydrogen, and consists chiefly of two gases, in which these elementary substances exist in definite proportions. One of these gases is termed carburetted hydrogen, and the other olefiant gas or bicarburetted hydrogen. The former contains one atom of carbon united with two atoms of hydrogen, and the latter an atom of each of these elements.

Light yielded by carburetted hydrogen chiefly derived from the carbon.

Of these two compounds of hydrogen and carbon, that which contains the largest proportion of the latter element is found to yield during its combustion the most brilliant light, and that too for a longer period of time. And, indeed, so great is the difference in these respects, that the hydrogen may not improperly be regarded as the mere solvent or vehicle of the carbon, acting the part of wick, and thus presenting that substance in a state sufficiently comminuted for its more perfect combustion. Accordingly, the more abundantly the hydrogen is impregnated with carbon the greater may we expect to be its illuminating power, and the fitter in every respect for yielding artificial light. These views are fully supported by experiment; for not only is the brilliancy of the light modified by the quantity of carbon held in solution by the hydrogen, but the time which a given portion of the gas takes to consume away by combustion is affected by it in a still greater degree.

Deterioration by admixture with hydrogen.

To determine in what ratio the illuminating power of the gases obtained both from oil and coal was reduced by diluting them in various proportions with hydrogen, we instituted a series of experiments, the results of which are of importance inasmuch as they indicate not only that the mixture is deteriorated, but that the same quantity of carbonaceous matter yields less light the more largely it is diluted with hydrogen.

In the first experiment we took a portion of coal-gas of the specific gravity ·67, which we found to consume at the rate of 4400 cubic inches per hour, and yielded the light of eleven candles, being 400 cubic inches per hour for the light of one candle. This gas being diluted with a fourth part of its bulk of pure hydrogen, acquired the specific gravity ·55, and wasted away at the rate of 6545 cubic inches per hour, yielding the light of ten candles. As a fifth part of the compound gas was hydrogen, the remaining four-fifths, amounting to 5236 cubic inches, was the quantity of the coal-gas which in its diluted state gave the light of ten candles for an hour; so that 524 cubic inches of the original coal-gas were requisite to give the light of one candle for the same time. But, in its unmixed state, 400 cubic inches were sufficient to give the light of one candle for an hour; and consequently, the deterioration occasioned by the dilution was in the ratio of 524 to 400, or of 100 to 76, being 24 per cent. It must be distinctly kept in view that the deterioration has been reckoned, not with respect to the whole volume of the mixture (in which case it would have been 39 per cent.), but simply in reference to the coal-gas itself; and therefore the experiment, so far as it goes, justifies us in adopting the conclusion, that had the hydrogen existed originally in union with the coal-gas, the latter would have improved in quality 24 per cent. by its abstraction; because the residuary portion would not only have lasted longer, but yielded during its combustion a superior light.

In a second experiment, conducted in a similar manner, in which the proportion of hydrogen was one-third of the quantity of the coal-gas, the deterioration was 27 per cent.; in a third experiment, the proportion of hydrogen being a half of the volume of the coal-gas, the deterioration amounted to 31 per cent.; and in a fourth experiment, the quantity of hydrogen being exactly equal to that of the coal-gas, the deterioration extended to 36 per cent.

General conclusions.

These results indicate a progressive deterioration in the quality of coal-gas by the admixture of hydrogen; and the important conclusion to which they lead is, that the abstraction or removal of the latter, though diminishing the entire volume, would improve the nature of the residuary portion not only in a higher ratio than the loss which the whole sustained in its bulk, but render that portion capable of yielding, for a longer period of time, a greater light than it could have done in its original state. Hence it may be inferred that the illuminating power of coal-gas, whether considered with respect to the cost of its production or the intensity of its light, admits of being improved; first, by impregnating the hydrogenous element more largely with carbon; secondly, by preventing the disengagement of hydrogen in a free state during the carbonization of the coal; and lastly, by detaching a portion of that gas from coal-gas when it already exists in admixture with it.

Modes of improving coal-gas.

The first of these modes of improvement seems to be practicable, at least to a certain extent, by thoroughly drying the coal before it is introduced into the retorts, and modifying the pressure under which the gas is generated; the second, by preventing the gas after its formation from being exposed to a high temperature by allowing it to pass over very hot surfaces, the effect of which is to deprive it of carbon. The second object may also be assisted by arresting the process of distillation at an earlier period than is usually practised, hydrogen and carbonic oxide being the products which predominate during the last periods of decomposition. On this point, however, the interests of the public and of the manufacturer are at variance. The consumer pays by measure, and hence it is the interest of the manufacturer to carry on the process of distillation as long as possible, for, by so doing, not only does he increase the quantity of gas but he improves the quality of the coke. With respect to the third mode of improvement, we are unfortunately, in the present state of our knowledge, acquainted with no method of detaching hydrogen from the gases with which it is mixed in oil or coal gas that would not impair the illuminating power of these gases to a greater extent perhaps than the benefit that would be derived from the removal of the hydrogen. A plan has been proposed by Mr Lowe to increase the quantity of carbon in the gas by impregnating it with the vapour of coal naphtha; for which purpose it was proposed to fill the wet gas meter at the house of the consumer with purified naphtha, and to maintain it at the same height by means of a reservoir connected with the meter; by which means the gas would be measured and saturated with naphtha at the same time. A more practical plan was to pass the gas through an ornamental vase containing a sponge saturated with naphtha, and placed at some point between the meter and the burner.

Deterioration of coal-gas by the separation of its particles, by nitrogen.

To determine the diminution of the illuminating power produced by separating the particles of the inflammable gas during its combustion, and thus diminishing the temperature of the flame, it occurred to the writer of the present article that nitrogen, having neither the property of supporting combustion nor of adding to the quantity of combustible matter submitted to that process, was well fitted to answer the intended purpose; and accordingly, on mixing coal-gas of ordinary quality (which, when burnt alone, yielded the light of twelve candles when it consumed 5400 cubic inches per hour) with varying portions of nitrogen, results were obtained which implied that the diminution of the intensity of the light proceeded in a ratio much more rapid than was observed when the gas was diluted with hydrogen. Thus, when six volumes of the coal-gas were mixed with one volume of nitrogen, the expenditure per hour was 6000 cubic inches, and the light equivalent to that of nine candles, being 667 cubic inches per hour for the light of one candle. But one-sixth of the whole being nitrogen, the remaining four-sixths, amounting to 556 cubic inches, was the quantity of the coal-gas which, in its diluted state, afforded the light of a candle for an hour. On the other hand, the quantity of the coal-gas requisite, in its unadulterated state, to give an equal degree of illumination being $\frac{5400}{12}$, or 450 cubic inches, it follows that the deterioration was in the ratio of 556 to 450, or 100 to 81 nearly.

By diluting the same coal-gas with other proportions of nitrogen as subjoined, and afterwards applying to each of the results the same kind of reduction as that which we have already made, we have deduced the following table, which exhibits the gradual deterioration of the illuminating power of the same quantity of coal-gas, produced by the mere separation of the atoms of the gas during its combustion.

Volumes of Coal-gas.	Volumes of Nitrogen.	Illuminating Power
60	0	100
60	10	81
60	12	69
60	15	55
60	20	37
60	30	29
60	60	4

By carbonic acid.

When carbonic acid was used instead of nitrogen, similar results were obtained; only the deterioration was considerably greater. Thus, when five volumes of the coal-gas were mixed with one volume of carbonic acid, the illuminating power was reduced from 100 to 30, whereas in the case of the nitrogen it was from 100 to 69. It is therefore a fortunate circumstance that carbonic acid, which is so apt to be generated during the production of coal-gas, and has so debasing an influence upon its illuminating power, is readily absorbed by a variety of substances; while nitrogen, the less injurious as well as the less abundant accompaniment, cannot be separated from the other gases with which it may exist in mixture by any process yet known.

Deterioration of Gas by keeping it after it is prepared.

Both oil and coal gas suffer, by keeping, a gradual loss in their power of illumination, which seems to increase in a more rapid ratio than the time they are kept. The deterioration, though greatest when the gases are allowed to stand over water, takes place in a considerable degree even when they are kept over oil, or in air-tight vessels. Hence it may be presumed that the carbon held in solution by the hydrogen is separated from that element, partly by its own gravity, and partly perhaps by solution in the water, or by condensation in the liquid form.

Deterioration of oil and coal gas when kept over water.

To whatever cause the deterioration is owing, the fact itself is undoubted. Thus, an oil-gas which, when newly prepared, had the specific gravity 1·054, gave the light of a candle for an hour when it consumed 200 cubic inches; kept two days, it gave the same light with a consumpt of 215 cubic inches per hour; and kept four days, it required for the same light 240 cubic inches per hour. In the case of a portion of coal-gas, which, when newly prepared, required 404 cubic inches to yield the light of a candle for an hour, the same gas kept two days required 430 cubic inches; and kept four days, 460 cubic inches to yield the same light. These results indicate a progressive deterioration in the quality of the gases, increasing with the length of time they are kept; and it is deserving of remark, that in both gases the diminution of the illuminating power decreases in a faster ratio than the time increases. After being kept three weeks, the oil-gas was so much debased in quality that it required 606 cubic inches of it to yield the light of a candle for an hour; and hence its illuminating power was reduced to one-third of what it was when the gas was newly made. From these experiments it may obviously be inferred that both oil and coal gas should be used as soon as possible after they are prepared.

Economy of Coal-Gas.

Gas superior to other modes of illumination, both in point of economy and convenience.

Among the advantages which have resulted from the introduction of coal-gas, we may reckon, first, its comparative cheapness; and, secondly, its superiority to all the other modes of artificial illumination.

In forming a comparative estimate of the cost of coal-gas and that of the other means employed for procuring artificial light, we may contrast it with the expense of wax, tallow, and oil, the ordinary substances used for the purpose. It deserves to be remarked, however, that while the price of coal, in consequence of the regular and abundant supply of that article, is liable to little fluctuation, the cost of wax, tallow, and oil, on account of the more precarious nature of the sources from which they are obtained, varies exceedingly in different seasons. The very extensive use, too, into which coal-gas has been brought, has produced a considerable effect upon the price of oil and tallow, as well as of wax; so that a comparative estimate of the expense of procuring the same extent of illumination from coal-gas and from these substances must appear less favourable to the former than would have been the case had the comparison been made when gas was first introduced. But by way of illustration, the approximative economy of the substances commonly employed for illumination may be contrasted as follows:—Supposing that 5 cubic feet of gas per hour give a light equal to that of 12 candles, then 1000 cubic feet, if burnt at the rate of 5 feet per hour, would give a light equal to that of 12 candles for 200 hours, at the cost of 4s. 6d., which is about the average price of gas in London per 1000 feet at the present time (1855). Suppose the candles to cost 9d. per lb., then 2 lb. of candles, 6 to the lb., would burn for 6⅔ hours, at the cost of 1s. 6d., or 60 lb. would burn 200 hours, at the cost of L.2, 5s. Assuming wax to be three times the price of the candles, the cost of wax candles for 200 hours would be L.6, 15s.; and taking sperm oil at 8s. per gallon, 4 gallons would give a light equal to that of 12 candles for 200 hours, at a cost of

L.1, 12s. So that, by comparing the cost of these various sources of light for equal periods of time, we have—

	L.	s.	d.
For wax candles, the cost of	6	15	0
For tallow candles, „	2	5	0
For sperm oil, „	1	12	0
For gas, „	0	4	6

The expense of gas, as compared with that of the other sources of light, will be—

Gas	1·0	Candles	10·0
Oil	7·1	Wax	30·0

In the above comparison we have taken London gas as the standard, which is scarcely fair, seeing that this gas is inferior in illuminating power to that of most other towns.

But the light obtained from coal-gas is not only procured at a smaller expense; it is also more convenient for most purposes than the light yielded by other substances. In the ordinary mode of lighting by tallow and oil, the light derived from their combustion cannot be diminished in intensity without considerable disadvantage and trouble; whereas in the case of gas, it may be reduced in an instant from the most perfect splendour to the feeblest degree of illumination by the simple adjustment of the stop-cock. The advantages arising from this easy method of regulating the light of gas, when it is used in the chambers of the sick, and indeed in all apartments where a variable but uninterrupted supply of light must be kept up, can only be duly estimated by those who have experienced them. To every branch of manufacturing industry which requires a steady and powerful light, the benefits which have resulted from the introduction of coal-gas are not less important. In many operations the light may be conveyed by means of flexible pipes, connected together with ball-and-socket joints, so as to be almost in contact with the fabric it is intended to illuminate, without the slightest risk of injury; and it may be kept in the same state for many hours in succession, or altered, as circumstances may render necessary.

For lighting churches, theatres, and other public buildings, where a strong and uniform light is required, gas answers the purpose more effectually than any other mode of illumination; partly from the facility of its application, and partly from the diversified and tasteful manner in which the jets of flame may be exhibited in various kinds of burners.

As a street light, its superiority is universally admitted; and from that application of gas it cannot be doubted that the metropolis, and other large towns, have derived great additional security against the perpetration of nocturnal crimes, as well as the means of carrying on the ordinary business of life during the evening with nearly the same convenience as during the full light of day.

Secondary Products.

The chemistry of the gas manufacture has been for some years in a state of mutation, the effect of which has been to bring about important changes in the nature and amount of the secondary products. We may, however, refer to the methods of disposing of the usual secondary products, namely, the coke, the tar, and the ammoniacal liquor. A ton of Newcastle coals of the average weight of 2240 lb. yields—

1 Chaldron of coke	=	1494	lb.
12 Gallons of tar	=	135	„
10 Gallons of ammoniacal liquor	=	100	„
9000 to 10,000 Cubic feet of gas	=	291	„
Loss	=	220	„
		2240	lb.

It is found, on an average, that 1 cwt. of coals yields about 2 bushels of coke. About one-fourth of the quantity of coke produced is used as fuel for heating the retorts, and the remainder is sold. The tar and ammoniacal liquor or gas-water separate in the tar cistern, the tar forming the lower stratum. This is used in the manufacture of patent fuel and of creasote, and as a rough paint for out-door work 100 lb. of tar yield by distillation about 26 lb. of an oily liquid known as *coal-oil.* A light product first distils over, which is called coal-naphtha; the remaining pitch is used for paying the bottoms of ships, wooden piles, &c. The coal-naphtha is used for dissolving caoutchouc, and for burning in the naphtha-lamp. The ammoniacal liquor is used in the manufacture of sal-ammoniac, carbonate of ammonia, and prussian-blue. The presence of cyanogen in the ammoniacal liquor has led to its employment in the manufacture of ferrocyanide of iron or prussian-blue. It is stated that a gallon of ammoniacal liquor, when saturated with sulphuric acid, contains enough of cyanogen and cyanates to form, with a salt of iron, 24 grains of prussian-blue.

The secondary products of the Edinburgh gas works are turned to account at the chemical works, situate at a distance of about two miles from them, the gas works being on a lower level. They are, however, connected by a line of pipes, and the gas liquor is lifted over the shoulder of the Calton Hill by means of a force-pump. The difference of level is then sufficient to carry it to the chemical works. The liquor is left for the tar to subside, but the ammoniacal liquor, consisting of an impure solution of carbonate and hydrosulphuret of ammonia, still contains a portion of tar, which is got rid of by distillation. The larger portion of the distilled liquid is converted into sal-ammoniac, and a portion into sulphate of ammonia. In order to obtain the sal-ammoniac, the liquor is neutralized with hydrochloric acid, and is then pumped into large cauldrons and evaporated to the crystallizing point, when it is drawn off into large vats, and on cooling deposits small feathery crystals; these are transferred to a stone chest, and are dried by the heat of a furnace below. The salt then resembles brown sugar; it is mixed with charcoal powder for the purpose of reducing any oxide of iron which may be present, and thus to get rid of the brown tint in the process of sublimation. The subliming vessels resemble a man's hat, and are arranged in the furnace with the crown downwards; they are about three feet in depth, and two and a half in diameter, and they contain sufficient for a week's charge. Each pot is covered with a leaden cupola, luted on with clay, and the salt is at first allowed to sublime away through a hole in the centre. This occasions some loss, but it appears to be a necessary precaution to prevent porosity in the sublimate. The central hole is then plugged with clay, and the sublimation is continued for a week. In this way hemispherical cakes of sal-ammoniac are produced; they are rasped on the surface to remove crust or colouring matter, and are broken into wedges, which are packed in barrels for exportation.

In preparing sulphate of ammonia the distilled ammoniacal liquor is saturated with sulphuric acid, and concentrated until small crystals are formed, which are removed by perforated ladles, dried, and packed in barrels lined with paper.

The tar, which contains a considerable portion of water, is transferred to a still, where crude naphtha and vapour of water distil over. They separate in consequence of their different densities, and the naphtha is digested with sulphuric acid in a leaden trough. This separates ammonia and other substances; the acid is removed by means of quicklime, the naphtha is washed with water, distilled, and is ready for the market. The remaining tar is raised to a higher temperature, and a liquid less volatile than naphtha is produced; it is termed *pitch-oil*, and is used for impregnating wood, &c. The pitch in the still is then run out, when it settles into a soft solid, for which at Edinburgh no market has yet been found, but it may probably be turned to account as a cheap fuel.

Scarcely any market is found for the tar, which was formerly largely consumed at Continental seaports. The increase of gas-works on the Continent, and the absence of duty on foreign tar as distinguished from British tar, has greatly retarded the sale of the latter abroad.

Since the introduction of the Boghead cannel coal, a new secondary product has been obtained in the form of paraffine. It is separated at the Westminster gas-works as paraffine-oil, and is used for lubricating the machinery.

(A. A—N. & C. T.)

GASCONY, *Fr.* GASCOGNE, an old province of France, out of which have been formed the departments of Landes, Gers, and Hautes Pyrénées, and parts of those of Haute Garonne and Ariège. Its capital was Auch.

GASSE, a district and county of Lower Canada lying between the estuary of the St Lawrence and Chaleur Bay, having an area of 7296 square miles and a population (1851) of 10,904. On its eastern coast is Cape Gaspé, forming the northern boundary of the Bay of Gaspé, an inlet of the Gulf of St Lawrence about 18 miles in length by 6 in width.

GASSENDI (PIERRE GASSEND), one of the most distinguished philosophers of the seventeenth century, was born in the last decade of the sixteenth (22d January 1592) at the village of Chantersier, near Digne in Provence. His family was humble, but his parents were virtuous; and to their instructions and influence Gassendi seems to have owed a more than usual debt of gratitude. His childhood exhibited the most astonishing, not to say incredible, precocity; and, if the feats told of him are true, shows (as M. De Gerando observes in his able sketch of this philosopher in the *Biographie Universelle*[1]) that the feeling which is apt to regard unusual precocity as a treacherous omen is not always to be trusted. At the age of four, Sorbière tells us, he sometimes played among his youthful companions the part of a censor, and imitated the manner of a preacher. At the same tender age he often crept out at night to watch the stars—to the great alarm of his parents. At ten he declaimed in a tiny harangue before the Bishop of Digne (Antony of Boulogne), on the occasion of a pastoral visitation; which struck that prelate (as it well might) with such wonder, that he did not hesitate, in spite of the aforesaid general distrust of precocity, to prophesy the boy-orator's future eminence. Either that, or an early grave, or speedy fatuity, would certainly be a very rational deduction from symptoms of such premature mental activity.

Gassendi was then receiving lessons from the curé of the village; but such was his ardour, that when he had learned the prescribed tasks, he would pursue his solitary studies by the light of the church lamp. At Digne he studied rhetoric, and composed certain *petites comédies.* He then went to Aix to study philosophy under Fesaye, a professor who strongly shared and expressed the rising discontent with the reigning scholastic philosophy. At sixteen our still beardless philosopher was elected to the chair of rhetoric at Digne; but, being destined for the church, speedily returned to Aix to study theology, and other branches appropriate to the ecclesiastical profession. At the early age of twenty-one he was simultaneously elected to the two chairs of philosophy and theology in the university of Aix. He chose the latter, and delivered his first course extemporaneously. He retained this chair for ten years. Not content with merely fulfilling the duties of his chair, he indulged in ample excursions into almost every department of science and literature, and made large collections of notes, which were afterwards of great service to him as a philosophical critic. His favourite pursuits in his leisure hours were astronomy and anatomy. He confesses, too, to a passing *penchant* for astrology; but it soon disappeared, and he became one of the most strenuous opponents of that delusive science. In 1623 he was presented to a benefice in the cathedral of Digne, and gave up his chair in order to surrender himself more completely to study. In the following year he commenced author by the publication of a portion of his *Exercitationes paradoxicæ adversus Aristotelem*, a work which naturally called forth, in equal measure, the censures of the servile lovers of antiquity, and the admiration of the ardent minds who longed to inaugurate a new era in science and philosophy. He himself, according to M. De Gerando, seemed half astonished at the report of his own artillery.[2] But being now committed as author, he desired, says the same writer, "s'éclairer par des observations et des conseils et former des relations utiles." With this view he made excursions in Provence and Dauphiné, visited the capital, and took a journey to the Low Countries and Holland—everywhere forming friendships with the literati of the age, haunting learned establishments and consulting public libraries. With similar views, as a pilgrim of science, he projected, in common with other learned men, a journey to Italy and Constantinople, but this design he never executed. During his stay at Marseilles in 1636 he made some important astronomical observations; and, by the aid of lunar eclipses, ascertained more correctly the limits, in latitude and longitude, of the Mediterranean, the length of which hydrographers, following Ptolemy, had exaggerated in the current charts by no less than 200 leagues. In 1638 he found an ardent friend and admirer in Louis de Valois, afterwards Duc d'Angoulême; and if the philosopher, who ever preferred studious retirement to public life, had been ambitious, he might have availed himself of this patron's aid to secure station and riches. In 1645 there was some thought of making him tutor to the young prince, afterwards Louis XIV., but it came to nothing. He was appointed, however, mathematical lecturer in the Royal College of France by the good offices of the Archbishop of Lyons, brother of Cardinal Richelieu. From that ambitious minister himself he never received any favour; which, says De Gerando, is remarkable, considering the affection of the archbishop and the renown of the philosopher. But, too often, politicians regard neither affection nor merit where talents cannot be serviceable to them, and Gassendi's modest and retiring spirit was little likely to help the ambitious cardinal. Meantime, his fame gradually spread. Amongst his ardent admirers appear royal and noble names:—Christina, Queen of Sweden; Frederick III. of Denmark; a couple of popes; and several French princes. The Cardinal de Retz also highly esteemed and honoured him. But he has more legitimate claims to remembrance than the suffrages of contemporaries illustrious only for rank and station; and indeed, with the exception of De Retz, he is himself better known now than any of the above-mentioned admirers. A more emphatic testimony to the deserved esteem in which he was held is found in his intimacy with all the great literati and philosophers of his day, with most of whom he maintained an active correspondence which forms by no means the least interesting portion of his works. A formidable list of these illustrious friends and acquaintances is given in Sorbière's "General Preface" to Gassendi's works. Galileo conferred upon him signal proofs of esteem, and Gassendi consoled Galileo in his persecutions; though, like Descartes, he prudently declined any chance of sharing them. The martyrs of science have been always scarce.

---

[1] The facts of Gassendi's life are abridged from this article and Sorbière's General Preface to the *Opera Omnia.* The limits of a work like the present necessitate brevity, and allow but scanty space even to the writer of six folios. The reader is referred for fuller information to the above preface, entitled *De vitâ et moribus Petri Gassendi*; to Brucker's *Hist. Crit. Phil.*, vol. iv., and *Appendix*; and to De Gerando's *Histoire comparée des systèmes de philosophie*; ample references to other sources will be found in the *Biographie Universelle*, vol. xvi., p. 532, 533.

[2] "Il parut presque intimidé lui-meme de l'avoir tenté."

The lectures of Gassendi at the Royal College were well attended. To astronomy, which had been too much neglected, he gave due prominence. Public speaking, however, was injurious to his lungs, which were always delicate, and he was at length compelled to desist. He then repaired to Digne for the benefit of his native air, and also spent some pleasant time under the hospitable roof of his friend and patron Louis de Valois, Earl of Alais. During this interval he was chiefly occupied in composing his biographies. He finally returned to Paris, where, after a long and gradual decay, he died October 14, 1655. His death is said to have been hastened by the mad phlebotomy then in vogue. He himself had often condemned the practice; somewhat inconsistently, it will be thought, since he allowed himself to be killed by the Sangrados of his day. He is said to have reconciled himself to the treatment to which he submitted, though he could not approve it, by the thought that the weakness it induced would probably diminish the pangs of dissolution. His last words, as he begged his attendant to feel the feeble pulsation of his heart, were, "You see what man's life is!" He was buried in the church of St Nicholas des Champs, where he is honoured by a mausoleum and bust.

The countenance of Gassendi is very imposing. The broad, massive brow, full eye, and expressive contour of the face, bespeak a mind full of intelligence, vivacity, and benevolence.[1]

The character of Gassendi's intellect is everywhere indicated by his works;—it was *critical* rather than *inventive*. Probably no one was ever better qualified to be a genuine historian of philosophy, possessing as he did keen analytical skill, in conjunction with profound and accurate erudition. His *Syntagma Philosophicum* everywhere displays these characteristics. It is a vast attempt to exhibit in one encyclopædic view the entire circle of science as then known;—logic, physics, physiology, ethics, all find a place there. Subjects are discussed with a minuteness, copiousness, and patience, which remind one of the style in which questions, equally subtle and intractable, and not always more profitless, are treated in the *Summa Theologiæ* of Thomas Aquinas. Gassendi's powers of acquisition must have been singularly active; nor was his logical acuteness, or the liveliness of his imagination, much inferior to the promptness and retentiveness of his memory. His learning is never mere learning; like that of many of his erudite contemporaries, it ministers to his intellect, but does not oppress it. The vivacity of his mind animates and penetrates the mass; and the acuteness of his reasoning and the exuberance of his illustrations relieve of much of their tedium discussions in themselves often uninviting enough.

The intellectual characteristics of Gassendi, as compared with those of the far more original and profound Descartes, are sharply set off in a long and elaborate parallel in the article by De Gerando in the *Biographie Universelle*, and it will be well to find space for a translation of a few of its more discriminating touches. "There was no less opposition," says he, "between the character of their minds than between the principles of their systems. The genius of Descartes, full of originality, energy, and audacity, aspired in all things to *create;* the understanding of Gassendi, reserved, prudent, calm, and investigating, contented itself with a sound judgment of everything; Descartes, shut up in himself, strove to reconstruct universal science by the force of meditation alone; Gassendi, observing nature, studying the writings of all ages, strove to co-ordinate facts, and to make an enlightened election among opinions. The former, proceeding in the track of the geometers, deduced from a few simple principles a long train of corollaries: the second, imitating the naturalists, collected a great number of given facts in order to draw solid deductions from their comparison. The former evinced admirable ability in the art of forming a system, the latter excelled in the criticism of other people's systems. The one, an absolute dogmatist, loved to speak in the style of a master, perhaps because he was conscious of profound convictions, and did not patiently bear contradiction; the other, a skilled dialectician, unravelled objections with art, distrusted himself, and easily entertained doubts which presented themselves. The one made great and veritable discoveries, and at the same time wandered into rash hypotheses; the other brought together a great number of partial truths, and, above all, destroyed a great number of errors."

The qualities of Gassendi's mind are perhaps nowhere more distinctly marked than in his commentary on the *Tenth Book of Diogenes Laertius*, and his tractate on the life and philosophy of Epicurus. In his attempt to ascertain, illustrate, and defend the philosophy of his favourite Epicurus, there was ample scope for his exuberant learning, his critical acumen, and his eclectic tendencies. It is a pity that he should have been so inordinately enamoured of this Greek philosopher; for his strong expressions have invited accusations, and even given colour to them, which seem wholly unfounded. Whatever his predilections for the atomic philosophy, he explicitly repudiates the irreligious dogmas founded upon it; and acknowledges that a supreme intelligence alone created and organized matter, alone imparted and conserves its laws and properties. "Metaphysics, morals, and physics," says M. de Gerando, "are conformed to the opinions of Epicurus; *yet* with the modifications which the principles of Christianity demand." Whether even the eclectic criticism of Gassendi could *quite* harmonize such materials, even by the most judicious selections and rejections, may be a question; but that he sincerely *thought* he had advanced nothing contrary to Christianity, is evident from the entire tenor of his declarations; and he must be believed unless we are determined on a more unpleasant alternative—that of supposing him at least as great a hypocrite as philosopher.[2] If the works just referred to exhibit as distinctly as any the more marked features of Gassendi's intellectual character, it is the *Syntagma Philosophicum*, of course, which displays all the endowments of this great philosopher in their amplest form. The remarks on the *Meditations* of Descartes, however (supplied at the request of Father Mersenne), best present many of its phases. They are marked by an acuteness and vivacity which he never surpassed.

As a metaphysician it has been mentioned that, however ingenious and learned, he is yet *critical* rather than

---

[1] The engraving in the folio edition of his works (1728) is in striking contrast with the grim effigies of Tycho Brahe and Copernicus in the quarto which contains Gassendi's lives of those philosophers. But it must be confessed the art of engraving had made prodigious progress in the interval.

[2] After avowing his orthodoxy very explicitly, he says, in the Proemial Book of his *Syntagma*, "Et videri quidem potest Epicurus arridere præ ceteris . . . . at non idcirco aut probo omnia quæ illius sunt,—*etiam* Religionis *non* attinentia placita; aut quæ probo non sic amplector ut indubia certaque habeam . . . ."—*Opera*, tom. i., p. 25. Edit. Florent.

creative. The same must be said of him as a mathematician and physical philosopher. His attainments in the mathematics were such as to elicit the praises of Barrow, no incompetent judge; and doubtless his fame might have been yet greater had he not, like Barrow himself, Pascal, Descartes, and so many other great mathematicians, varied or combined this study with so many very different pursuits. It seems, if we may judge by the conduct of almost every great mathematician from the time of those just mentioned to the present day, that, delightful as is the discovery and contemplation of mathematical truth, it cannot alone fill or content the mind. It is hardly possible to name instances of great mathematicians who are known *only* as great mathematicians, or who have not profoundly studied some branches either of physics or abstract science. Gassendi, according to Sorbière, avowedly valued mathematics chiefly as an indispensable instrument of discovery in physical science.

Ardently attached to the new philosophy of experiment, Gassendi was one of the first Frenchmen, if not the first, who fully appreciated Bacon, and, in introducing him to his countrymen, paid ungrudging homage to his genius.[1] Though such an admirer, however, of the new school of physics, he himself, as in other departments, made but moderate contributions to discovery. Here, too, his genius was *critical.* But it is not to be forgotten that he was the first to observe the transit of a planet across the sun's disc—verifying the prediction of Galileo—and that, as before mentioned, he made some valuable hydrographic corrections by means of lunar eclipses.

As Gassendi is among the most literary of philosophers, so is he also among the most voluminous. Six volumes folio attest the vastness of his industry, no less than his erudition and versatility. These have been twice printed; once at Lyons in 1658, under the editorship of Montmort and Sorbière, and once at Florence in 1728. The first two volumes are occupied entirely with his *Syntagma Philosophicum;* the third contains his critical writings on Epicurus, Aristotle, Descartes, Fludd, and Lord Herbert, with some occasional pieces on certain problems of physics; the fourth, his *Institutio Astronomica,* and his *Commentarii de rebus celestibus;* the fifth, his commentary on the Tenth Book of Diogenes Laertius, the biographies of Epicurus, Peiresc, Tycho Brahe, Copernicus, Peurbach, and Regiomontanus, with some tracts on the value of Ancient Money, on the Roman Calendar, and on the theory of Music; to all which is appended a large and prolix piece, entitled *Notitia Ecclesiæ Diniensis;*—the sixth volume contains his correspondence. The *Lives,* especially of Copernicus, Tycho, and Peiresc, have been justly admired. That of Peiresc has been repeatedly printed; it has also been translated into English. Gassendi was one of the first, after the revival of letters, who treated the *literature* of philosophy in a lively way. His writings of this kind, though too laudatory and somewhat diffuse, have great merit; they abound in those anecdotal details, natural yet not obvious reflections, and vivacious turns of thought, which made Gibbon style him, with some extravagance certainly, though it was true enough up to Gassendi's time—"le meilleur philosophe des litterateurs, et le meilleur litterateur des philosophes." Gassendi wrote in Latin; it is to be regretted that he did not compose some of his works in French. There is little doubt that he would have given us another specimen of that happy philosophical style in which his countrymen have so signally excelled from Descartes' time downwards; as it is, his writings, as might be expected from the qualities of his mind, are perspicuous and lucid in an eminent degree; but the style is very diffuse, and, in many cases, cumbersome, a fault which it may be reasonably supposed would have been obviated if he had written in his vernacular. His illustrations and examples, especially in the leisurely exposition of the voluminous *Syntagma Philosophicum,* are often multiplied to tediousness, though generally apt and well selected. Instances both of the merits and faults in question may be seen in the parts of the *Syntagma* where he treats "de Sensibus *speciatim,*" and (more briefly) in the chapter "de Instinctu Brutorum."[2]

The personal character of Gassendi must have been exceedingly attractive. Of his winning manners, agreeable social qualities, and modesty, there is a pleasing proof recorded by Sorbière, and pleasantly repeated by De Gerando. "Marivat having travelled from Paris to Grenoble in his company without suspecting his name, desired on arriving to be presented to the celebrated Gassendi. He was greatly surprised to recognise him in the amiable companion with whom he had conversed on the route. This behaviour reminds us of that of Plato when he returned from Syracuse into Greece." His temper and manners were such as became a philosopher, and a Christian philosopher rather than a disciple of Epicurus—whose precepts, if capable of being harmonized with virtue, are yet easily perverted to vice. It may be doubted whether any philosopher ever lived more philosophically than Gassendi, if we may judge by the testimony of Sorbière in the preface to the *Opera Omnia.* His eulogium records virtues which make us love the man even more than we revere the philosopher; and with a trait or two from it we shall conclude this notice of his character. "When I consider his private life, I seem to see before me some anchorite, who, in the midst of a crowded city, has set up the severe rule of the desert; so heartily did he embrace a life of poverty, chaste celibacy, and obedience, though unconstrained by any vows. Contented with little, he envied none their riches; none the richer for the patronage of the wealthy, he dispensed whatever he received with a liberal hand. He was voluntarily abstemious, rarely touched flesh, generally subsisted on vegetables, and breakfasted and supped on oatmeal porridge." Sorbière pronounces a deserved eulogium on his modesty, humility, and benevolence.

The precise character and position of the philosophic system of Gassendi has, like that of so many other philosophers, been much debated. It is a topic which there is no space to discuss here, but which cannot be wholly passed by, since from misapprehension Gassendi has been treated with less than justice by eminent philosophical critics, and among the rest by Dugald Stewart in the "Preliminary Dissertation."

By critics in general, fifty years ago, he would have been regarded as a genuine precursor of the naked and undisguised sensational French philosophy of the last century; by other and later critics, he is represented as having taught a philosophy not very dissimilar in its main principles from that of Locke. Locke, indeed, is even supposed by some to have derived more from the acute Frenchman than he has allowed the generality of his readers to suspect. Of this a word or two presently.

Meantime, the truth with regard to Gassendi seems to be, that, like many other philosophers who have written folios, and produced their works at distant intervals and under very different circumstances, he has not been altogether consistent in the exhibition of himself. Assuredly his tone is very different when urging with so much vigour all the possible "objections" which ingenuity could discover to Descartes' *Meditations*, and when systematically developing his own doctrines in his *Syntagma Philosophicum*. "The main scope," says Dugald Stewart in the Preliminary Dissertation, "of Gassendi's argument against Descartes is to materialize that class of our ideas which the Lockists as well as the Cartesians consider as the exclusive objects of the power of *reflection*, and to show that these ideas are all ultimately resolvable into images or conceptions borrowed from things external." If we look *only* at the animadversions on Descartes, there is much to favour these observations. But then, again, as Hallam justly observes, if we examine the *Syntagma Philosophicum*, even the Proemial Book, even the Logic, but more especially the important chapters in the Physics "De Phantasiâ" and "De Intellectu"—we cannot fail to perceive that this estimate is erroneous, and that Gassendi is very far indeed from resolving all the phenomena of mind into sensation. This Hallam has truly remarked, and has supplied a few extracts from the above chapters of Gassendi in proof. The explanation of the apparent discrepancies, this writer says, is difficult. "Whether he urged some of his objections against the Cartesian metaphysics with a regard to victory rather than truth, or, as would be the more candid and perhaps more reasonable hypothesis, he was induced by the acuteness of his great antagonist to review and reform his own opinions, I must leave to the philosophical reader."[1]

---

[1] "Is videlicet meditatus attendensque, quam sit exiguum, quod, ex quo tempore homines philosophari cæperunt, circa veritatem, intimæque rerum naturæ notitiam consecuti sunt; *ausu vere Heroico* novam tentare viam est ausus . . . ."—*Opera,* tom. i., p. 55. Edit. Florent.

[2] *Syntag. Phil. Physicæ,* part iii., sect. iii., lib. vii.; viii., cap. v.

It seems highly probable that both explanations are correct. In accepting Mersenne's invitation, issued by Descartes' commands, to find as much fault as possible with the celebrated *Meditations* (which made such pretensions to logical rigour), Gassendi would naturally be tempted to urge every objection to the uttermost; and would probably challenge the *proof* of assertions, when he thought it weak, not less where he agreed with the conclusions themselves than where he denied them. This seems to have been obviously his course in some cases.[2] In such a controversy the true position is apt often to be forgotten both by him who writes and by him who reads. Challenged to show the invalidity of the reasoning which is employed to support a given conclusion, the objector is apt to speak and to be interpreted as if he contended not only for the validity of his objections, but for an *opposite* conclusion from that of his opponent. This may or not be. In Gassendi's case it is sometimes the conclusion as well as the reasoning, sometimes the reasoning only, to which he is opposed.

From Gassendi's "objections" his own *positive* opinions on the points in question are not always inferrible. We must look at his dogmatical explanations of his own views as a safer criterion, and we find these in the *Syntagma*. It must be added that a certain degree of personal feeling evidently gave sharpness to his criticisms on Descartes; and, philosopher though he was, being still a mortal man, this could not but exert some influence. On the other hand, when writing his *Syntagma*, Gassendi was freed from all such bias; he was no longer the advocate but the judge; he had to show, not merely that such reasoning on behalf of such and such conclusions was not valid, but *what* conclusions he held himself. He had also had the opportunity of reading all his great antagonist's "criticisms" on his *own* "criticisms," and doubtless profited by them; and lastly, though the interval, as Hallam says, between the controversy with Descartes and the commencement of the ponderous *Syntagma Philosophicum* was but brief—the dates being 1641 and 1642—yet before its author had reached the chapters "De Phantasiâ" and "De Intellectu" (nearly 1000 closely-printed folio columns from the commencement), he would have had abundant time to review any opinions of an earlier date, and profit by the discussions with his illustrious opponent.

Be this as it may, the chapter on the "Human Intellect" shows incontrovertibly that Gassendi was far removed from the sensationalists. While he maintains constantly his favourite maxim "that there is nothing in the intellect which has not been in the senses;" while he contends that the imaginative faculty, "phantasia," is the counterpart of sense; that like that, as it has to do with material images, it is itself material, and essentially the same both in men and brutes,—the chapter "De Intellectu" plainly proves that he could consistently mean nothing more than that "sensations" are the invariable and indispensable antecedents and conditions of the evolution of the phenomena of intellect; for he admits that the intellect, which he affirms to be "immaterial" and "immortal"—the most characteristic distinction of humanity,—attains notions and truths of which no effort of sensation or imagination can give us the slightest apprehension.[3] He instances in the capacity of forming "general notions;" in the very conception of *universality* itself,[4] to which he says brutes, who partake as truly as men in the faculty he calls "phantasia," never attain; in the notion of God, whom he says we may *imagine* to be corporeal, but *understand* to be incorporeal; and lastly, in the "reflex actions" by which the mind makes its own phenomena and operations the objects of attention.[5]

His remarks on the last point—his very phraseology, "actiones reflexivæ," certainly remind one of Locke, and have suggested that Gassendi's system was the source of Locke's. It *was* so, exclaims Stewart, of the *false* system of Locke into which the sensational schools of France distorted that of the English philosopher. To this it seems sufficient to reply, as before, that Gassendi himself, in his more deliberate exhibition of his philosophy, does *not* belong to those schools. At the same time, whether Locke had ever studied the system of Gassendi is somewhat doubtful. That he was not, at all events, *conscious* of any signal obligations to Gassendi, may be inferred for the following reasons:—1. Locke's distinct assertion, to Stillingfleet and others, that, right or wrong, his system had been the fruit of his own excogitation. 2. That if he had consciously borrowed from Gassendi, he, who was a model of honour and candour as a writer, would not have failed to acknowledge his obligations. 3. The very name of Gassendi scarcely occurs in all his writings;[6] and though it may be said that this silence was natural if conscious that he had *stolen*, it is inconsistent with his character that he should have so acted; the silence would have become a thief, but not John Locke. 4. He was no *helluo librorum*, and the *Syntagma* extends to two ponderous folios. It is true that the abridgment by Bernier in 8 vols. (if such an abuse of the term may be allowed) was published in 1678, and this, Locke, who was certainly in habits of intercourse with Bernier at Paris in 1677, might have seen. 5. But, supposing him to have seen it, what then? The utmost that can be said is, that it is probable that the remarks on the reflex operations of the mind, and the terms "*actiones reflexivæ*" (used, however, by Gassendi not with a view to a classification of mental phenomena, *but incidentally, in proof of the mind's immateriality*) may have unconsciously suggested to Locke his second great division of ideas, and the phraseology in which he has couched it. But the observations themselves are far too scanty to have been of much service to Locke in constructing his general theory, still less in that elaborate and minute analysis of the "ideas of reflection" which constitutes the bulk of the "Essay." The whole of the two books on "Imagination" and "Intellect" in the *Syntagma* would not make above an eighth of Locke's "Essay," and the greater part of these is occupied with questions which Locke has expressly renounced as belonging to a hopeless psychology; as, for example, whether imagination be material or immaterial (Gassendi deciding for the former)—of how many kinds, or how, mechanically or physiologically, related to sensation—whether and in what sense it can be said to possess reason—whether it be identical with the similar faculty in brutes. Such questions, together with the history of opinions, Gassendi is as prone to discuss as Locke to decline them. The opinion of De Gerando, however, on the relations of Locke's philosophy to Gassendi's is well entitled to attention. (H. R.)

---

[1] *Literature of Europe*, vol. iv., p. 203.

[2] It must have been so when so severely challenging Descartes' *proof* of the immateriality of the soul, or of the existence of the material world, for Gassendi denied neither.

[6] He has just introduced his name in the controversy with Stillingfleet, and that is all.

GASTRIC JUICE (γαστήρ), the name given to a transparent and colourless fluid which is the principal agent in affecting those changes that constitute digestion, that is, which convert the aliment into chyme. This secretion has a saline and somewhat bitter taste, occasionally possessing acid properties, but probably in its natural and healthy condition being neither acid nor alkaline. It contains a small proportion of albumen, together with a matter which is either gelatin or mucus. But while it thus differs to all appearance in so trifling a degree from many of the other secretions, it yet possesses very extraordinary solvent powers over the substances usually employed as food. Even when made to act upon these substances in vessels out of the body, provided they are kept in a temperature equal to that of the human body, it will reduce them in a few hours to the state of a soft pulp, producing apparently the very same change which is induced upon the same species of aliment by the digestive process within the stomach. There are three ways in which the gastric juice acts on alimentary matter; the first is that of coagulation, which is exerted on all the fluid forms of albumen, whether existing in the serum of the blood, or the white of the egg, or in different secretions, more especially milk. It is by means of this property, indeed, that cheese is obtained from the coagulation of its albuminous portion by the addition of rennet, which is an infusion of the digestive stomach of a calf. The object of this coagulation appears to be to detain the substance for a longer time in the stomach, and subject it more completely to the solvent power of the same fluid, by its previous reduction to a solid form, which prevents its escape by the pylorus. The second kind of action is that of counteracting the tendency to putrefaction, and even to the acescent fermentation. This effect takes place in a remarkable degree in many carnivorous animals, which frequently take their food in a half putrid state, and in which the first operation of the gastric juice is to remove from it all putrescence; showing that this secretion possesses the property not only of preventing putrefaction from taking place, but also of suspending its further progress when it has actually commenced. The third species of chemical action exhibited by the gastric juice is that of solution. That this effect takes place independently of any concurrent mechanical operation of the muscular powers of the stomach has been very decisively proved by the experiments of Réaumur, of Stevens, and of Spallanzani. Those of Stevens in particular are highly valuable, as having been made on a man who was in the habit of swallowing stones, which he could afterwards, by a voluntary effort, reject by vomiting from his stomach. Taking advantage of this power, Stevens induced him to swallow hollow metallic spheres perforated with holes, and filled with different alimentary substances, which, after being allowed to remain a sufficient time in the stomach, were returned, and their contents examined. It was invariably found that the food under these circumstances of exposure to the gastric fluid alone, with protection from external pressure of a mechanical nature, was more or less completely dissolved, and reduced to the state of pulp. He afterwards pursued a similar train of experiments on dogs, causing them to swallow the perforated spheres, and after a certain time destroying the animals, and examining the changes effected in their contents. Spallanzani has also varied and multiplied experiments of this kind in a manner that leaves no room to doubt the truth of the conclusion deduced from them as to the solvent power of the gastric secretion. Dense membranes and even bones are reduced into a pulpy mass by this fluid in many animals, while at the same time many bodies of comparatively delicate textures, such as the skins of fruits, and the fibres of flax or cotton, are not in the slightest degree affected by it. This difference of action on different substances is analogous to the operation of chemical affinity, and corroborates the theory that digestion is effected principally by chemical agency. The results of these experiments have been fully confirmed by experiments made on the stomachs of persons who, in consequence of a wound, had a permanent opening into that organ from the exterior of the abdomen.

Portions of the stomach are sometimes found dissolved after death, more especially when death has occurred suddenly during the act of digestion. This effect can never take place during life, because the living structures resist the solvent power of the gastric juice. Acid is frequently developed during imperfect digestion; but it appears from the experiments of Dr Prout and others, that this effect is also attendant upon healthy digestion, and that it is principally the muriatic acid which is thus disengaged from its combinations, and makes its appearance in a free state. The lactic acid, which appears to be a modification of the acetic, is also present in considerable quantity. Tiedemann and Gmelin found the acetic acid always present in the gastric juice. They observe that many of the substances employed as food which are not soluble in water are so in the diluted muriatic and acetic acids at a high temperature, and they are inclined to ascribe to a chemical solution of this kind the principal change effected by digestion. Among the agents concerned in the digestion of the aliment, the high temperature at which the contents of the stomach and intestines are retained must be considered as one of the most important. While digestion is taking place, both orifices of the stomach are closed, and there often comes on a feeling of chilliness, especially in a weakly constitution, in consequence of the demand which the stomach makes upon it for an additional supply of heat to assist in the process. There is also disinclination to exertion, and frequently a tendency to sleep. Yet the indulgence in this disposition, as well as violent exercise immediately after a meal, tend equally to retard the formation of chyme. The circumstances most favourable to perfect digestion are gentle exercise, with cheerfulness, and moderate mental exertion.

GASTROTOMY (γαστήρ, and τέμνω *I cut*), the operation of cutting open the abdomen, as in the *Cæsarian operation*.

GATA, a town of Spain, province of Estremadura, 60 miles N. by W. of Cáceres, on the right bank of the river Gata. It is not well built, has narrow crooked streets, three small squares, a fine parish church with a tall spire; a chapel, a large town-house built in 1843, with the lower story for a prison, an hospital, and several schools. Its manufactures are linen and woollen fabrics, white wax, wine, oil, soap, and hats. Its trade is chiefly in these and in grain and cattle. The pop. in 1854 was 3762.

Gata, a secular town of Spain, in the province and archbishopric of Valencia. The district lies between those of Lliber and Jabea, and is very irregular and mountainous in surface, especially towards the east, where Mount Mongo stands. Gata is about 60 miles from Alicante, on the right bank of the Jalon, and contains nearly 2000 inhabitants. The surrounding district produces silk, almonds, raisins, figs, olive-oil, carob-fruit, wine, wheat and other cereal grains, maize, and pulse. The chief objects of industry are basket-making, and utensils for the cultivation of the dwarf-palm, which abounds in an indigenous state in this district.

Gata, *Rio de*, a small river of Spain, in the province of Estremadura. It rises near the town of the same name from numerous large springs in the Sierras de Gata, Jalama, Moncayo, &c., which all unite near a mill called the Infernal, on the road which passes between the Piezas de la Moraleja and Perales, afterwards falling into the Arrago, which joins the Alagon about four miles below the town of Casillas.

Gata, *Sierra de*, in Spain, a ridge of mountains between Leon and Estremadura, commencing east at the termination of the Peña Francia, and extending S.S.W. into Portugal, where it unites with the Serra de Estrella. Two branches nearly perpendicular to its axis shoot out from it; one north, forming the watershed between the Aqueda and the Coa; and the other south, between the Alagon and the Erjas. The main chain forms part of the watershed between the Tagus and the Duero or Douro. This entire chain is almost wholly composed of granite.

Gata, *Cabo de*, a headland of Spain, in Andalucia, in the province and 22 miles S.E. of Almeria, on the east side of the Gulf of Gata, in Lat. 36. 44. N. and Long. 2. 14. W. In the centre of the promontory of Gata are four hills; and a rocky mass about 80 yards from the beach, formed of crystallized limestone, rises to the height of 215 feet above the sea, and contains a marble quarry in which corundum and agates are found, and large masses of carnelian. Its ancient name was *Charidemi Promontorium*, the S. point of Hispania Tarraconensis. It lay directly opposite to the mouth of the river Malva in Mauretania. (Ptol. ii. 4, 7.)

GATAKER, Thomas, was born in London, in 1574, and educated at St John's College, Cambridge. From the year 1601 till 1611 he held the appointment of preacher to the Society of Lincoln's Inn, which he resigned on obtaining the rectory of Rotherhithe. In 1619 he published a curious treatise, historical and theological, *On the Nature and Use of Lots*, which gave rise to much controversy. Gataker, in order to allow the storm to subside, went on a tour to the Netherlands, where he confuted some of the English Papists in Flanders. In 1642 he had the honour of being appointed one of the Assembly of Divines who met at Westminster, having obtained much celebrity from his *Opera Critica*, and other remarkably able works, chiefly on sacred literature. The part of the Assembly's Annotations upon the Bible executed by him are those on Isaiah, Jeremiah, and the Lamentations, which have considerable merit. At Westminster he disapproved of the introduction of the Covenant, and declared himself in favour of episcopacy. He zealously opposed the trial of Charles I; and from ill-health declined the mastership of Trinity College, Cambridge. He died in 1654. The best edition of his works is that published at Utrecht in 1668, folio. Echard says he was the most celebrated among the divines assembled at Westminster, being highly esteemed by Salmasius and other foreigners. He was alike remarkable for exemplary piety, charity, humility, and modesty; while his acquaintance with polite literature greatly increased his standing as a scholar.

GATEHOUSE, a burgh of barony and river port of Scotland, county of Kirkcudbright, on the Fleet, about a mile and a half above its influx into Fleet Bay, and six miles N.W. of Kirkcudbright. It stands in a romantic valley, surrounded on three sides by well-wooded hills. Brewing and tanning are carried on, as well as cotton and soap manufactures. The river is navigable for vessels of 180 tons. Market-day Saturday. Pop. (1851) 1750.

GATES, Horatio, an American general of the war of independence, was born in England in 1728. After serving in the English army and obtaining considerable promotion, he purchased an estate in Virginia, where he resided till the commencement of the revolutionary war in 1775. The immediate cause of his retirement was a wound which he had received while accompanying General Braddock in his unfortunate expedition against the French settlements on the Ohio in 1755. Having taken the popular side in the war of independence, Gates was appointed by Congress adjutant-general; and during the struggle he amply justified the high confidence placed in him by rendering many brilliant services to his adopted country. In 1776 he was appointed to command the army on Lake Champlain; but his conduct here not having been approved of, he was superseded in the following spring; yet in August he was sent to oppose General Burgoyne, whom he totally defeated on the 16th of October and compelled to surrender his whole army, which was justly considered the most important achievement of the war from its having the greatest effect in procuring the result that followed. After obtaining the chief command, however, in the southern districts, Gates was signally defeated at Cambden, in South Carolina, by Lord Cornwallis, on the 16th of August 1780. He was now superseded in his command by General Greene; and it was intimated to him that Congress had also resolved to submit his conduct to a court of inquiry. The investigation continued till after the close of the war in 1782; but it terminated in acquitting him fully and honourably of any blame, as his defeat had been unavoidable in the disorganized state of the army he commanded against Cornwallis. After this he again retired to his Virginian estate, whence he removed to New York in 1800. On his arrival he was immediately admitted to the freedom of the city, and then elected a member of the State Legislature. We should not omit to mention that before his departure from Virginia he performed the noblest act of his life—the emancipation of his slaves, accompanying their manumission with a provision for those who needed assistance. He died on the 10th of April 1806, aged 77 years.

GATESHEAD, a municipal and parliamentary borough and market-town of England, county of Durham, on the right bank of the Tyne, opposite Newcastle, with which it is connected by a handsome stone bridge, as well as by a magnificent bridge of the York, Newcastle, and Berwick railway. The town consists of two principal and nearly parallel streets, from which others diverge in various directions. The parish church is an ancient cruciform edifice surmounted by a lofty tower. Besides the parish church there are St John's Church, Gateshead Fell, St Cuthbert's Church, St Edmund's Chapel, and places of worship for Presbyterians, Independents, Methodists, Roman Catholics, &c. Gateshead has extensive glass manufactories, iron and soap works, brick and tile works, rope-works, &c. There are numerous coal mines in the vicinity. At Gateshead Fell are large quarries for grindstones, which are much esteemed, and exported to all parts of the world. Gateshead is governed by a mayor, 6 aldermen, and 18 councillors, and returns one member to parliament. Pop. (1851) 25,568.

GATH, one of the five principal cities of the Philistines, and the birthplace or residence of Goliath. It was conquered by David, and fortified both by him and by Rehoboam. Under Jehoash, Hazael king of Syria took Gath, but it was recovered from his successor Benhadad. It must, however, have soon revolted; for Uzziah finding it necessary to war against the Philistines, "broke down the wall of Gath." "Gath," says Jerome (on Micah i.) "is one of the five Philistine cities lying near the confines of Judah, on the road from Eleutheropolis to Gaza; now it is a very large village." On Jerem. xxv. the same authority declares that Gath was not far from Azotus. Modern travellers give no description of the place (Reland, *Palæst.* p. 785, *sq.*)

GATSHINA, a town of Russia, government of St Petersburg, 30 miles S. by W. of the capital. It has a palace, formerly a favourite residence of the late empress, spouse of Alexander I., a foundling hospital, school of agriculture, and a porcelain manufactory. Pop. 7000.

GAUCIN or Gauzin, a secular town of Spain, in the province of Granada, and bishopric of Málaga, from which it is distant 48 miles W.S.W. It is situated on the slope of the Sierra del Hacho; or more accurately on the Serrania de Ronda, over against Gibraltar, between the Sierra Crestellina and Mount Heaho, on the eastern declivity of the Serrata. It is well built, its streets are steep, wide, clean, and well-paved; it has a chapel, a parish church, three squares, a handsome town and session-house, a prison, a granary, three schools, and an ancient strong Moorish castle occupying the summit of an adjacent rock, in an almost inaccessible position, and garrisoned by infantry and artillery. It has manufactures of brandy, wine, oil, cotton, linen, and woollen fabrics, hats, leather, and soap. Its trade consists chiefly in cloth, lace, silks, baize, fruits, wine, brandy, and cattle. The pop. in 1855 was nearly 6000.

GAUDEN, John, the reputed author of the "Icon Basilike," was born in 1605, at Mayfield in Essex, of which parish his father was vicar. He was educated at Bury St Edmunds, and afterwards at St John's College, Cambridge. Selecting the church as a profession, he obtained in 1630 the living of Chippenham, and various other valuable preferments in rapid succession. His promotion, however, speedy as it was, did not keep pace with his desires; and when the civil war broke out, he found himself under the sad necessity of siding with one or other of the two parties. Though probably a royalist at heart, he had the tact to seem favourable to the parliamentarians, and was rewarded for some supposed services with the valuable living of Bocking in Essex. He here outwardly conformed with all the requirements of the law; but judiciously resolving to be provided against the chances of fortune, wrote secretly a "protestation" against the king's trial, and a "Just Invective against those who murdered King Charles I.," besides other loyal effusions. None of these, however, appeared till two years after the Restoration. The most remarkable of them by far was the *Icon Basilike, or Portraiture of his Sacred Majesty in his Solitude and Sufferings,* which, in the course of one year, passed through fifty editions. The evidence on which Gauden's claims to the authorship of this work rest is very fully canvassed by Sir James Mackintosh, *Edinburgh Review*, vol. xliv., and by him pronounced satisfactory. For his service to the royal cause Gauden was made Bishop of Exeter, and afterwards of Worcester. He died in 1662; and it is said that his death was hastened by his poignant grief for losing the rich see of Winchester on which he had set his heart.

GAUDENS, St, a town of France, capital of a cognominal arrondissement in the department of Haute Garonne, on a hill near the left bank of the Garonne, 45 miles S.W. of Toulouse. It has tribunals of primary jurisdiction and commerce; a communal college; manufactures of serge and tape; sawing, paper, and other mills; and a brisk trade in agricultural produce. Pop. (1851) of town 4905, of arrondissement, 147,096.

GAUGING, the art of measuring the contents of casks or vessels of any form. Gauging forms a part of mensuration, but is frequently practised by persons unacquainted with its theoretical principles, who work by certain rules, with the aid of a gauging-rod, and by the sliding rule. The ordinary gauging-rod consists of four rules made of boxwood, each a foot long, and united by brass joints, so that it may be folded together. See Mensuration.

The term *gauge* or *gage* is applied in various ways, but always with reference to measure or proportion; or, in the literal sense of the word, to that which bounds or confines something else. Thus in physics it is applied to several instruments or apparatus for measuring the state of a phenomenon; such as the wind-gage, the rain-gage, the barometer-gage for measuring the degree of pressure of the air within the receiver of an air-pump, &c.: in architecture, to the length of a slate below the lap: in railway engineering, to the space between the rails; and the like.

GAUL. See Gallia, and France.

GAUSS, Karl Friedrich, an eminent German mathematician, was born of humble parents at Brunswick, April 23, 1777. He distinguished himself greatly while a student, and in his twenty-fifth year made his name widely known by his *Disquisitiones Mathematicæ*, a work full of the most subtle mathematical speculation applied to the higher branches of arithmetical science. In 1809 he published at Hamburg his *Theoria Motus Corporum Cœlestium*, which gave a powerful impulse to the true methods of astronomical observation, towards which much care was at this period directed. Two years before this time he had been chosen director of the Göttingen Observatory, an office which he retained till his death, despite the many tempting offers he received of more honourable and lucrative positions elsewhere. So attached was he to his university, and so closely bent on his studies, that he never but on one occasion slept away from under the roof of his own observatory. In that solitary instance he had accepted an urgent invitation from Humboldt to attend a meeting of natural philosophers at Berlin. His only other acknowledged work, *Theoria Combinationis Observationum Minime Erroribus Obnoxiæ*, appeared at Göttingen in 1823, and conferred a lasting boon on the cause of science; and many of his papers read before the society of Göttingen are hardly less valuable. Gauss was well versed in general literature and the chief languages of modern Europe, and was a member of nearly all the leading scientific societies of Europe. It is related that Laplace, when asked who was the greatest mathematician of Germany, replied, "Pfaff" (the teacher of Gauss). His questioner said he had thought Gauss even more profound. "Ah," said Laplace, "I esteem Pfaff the greatest mathematician in Germany; but Gauss the greatest mathematician in Europe." Gauss died at Göttingen early in the spring of 1855.

GAUZE, a very light transparent textile fabric, made sometimes of silk and sometimes of linen thread. It is said to have been invented at Gaza in Palestine, and hence the name.

Gauze Wire-cloth, a textile fabric of wire, more or less fine. It is used for safety-lamps, sieves, framed window-blinds, &c.

GAVIA-GRANDE, a secular town of Spain, in the province and archbishopric of Granada. It is situated in a plain on the left bank of the Genil, and surrounded with beautiful gardens and fields of the richest verdure, teeming with grain and fruits in their season. It contains a parish church, a primary school, and has manufactures of linen, several oil-mills, gypsum and stone quarries, as well as a good trade in flax, hemp, and corn. It is three miles distant from Granada, and has a population of nearly 5000.

GAVIA, Gabia, or Gavea, in Brazil, a group of mountains in the Tijuco range, in the province of Rio de Janeiro, near the coast. It is about 16 miles S.E. of Rio de Janeiro, in Lat. 23. N. The highest peak, named from its appearance "Topsail mountain," is designated by English mariners "Lord Hood's Nose." It is flat on the top, and composed mostly of granite, rising almost perpendicularly from the sea to the height of 2100 feet. At its base are the bar and roadstead of the Rio Tijuco.

GAVIAO, a town of Portugal, in the province of Alentejo, on an elevated situation near the left bank of the Tagus (Tejo). It is 22 miles N.W. of Crato, and contains a population of nearly 2000. An annual fair of three days is held here.

GAVEL-KIND, in English law, a species of tenure of lands, which previous to the Norman conquest is supposed to have been the general custom of the realm, and which exists to this day in Kent, in consequence, it is said, of the success that attended the struggles of the Kentish men to preserve their ancient liberties. The chief distinguishing properties of gavel-kind are—that the lands descend not to the eldest, youngest, or any one son only, but to all the sons together; that the tenant may aliene his estate at fifteen years of age by means of a feoffment; and that the estate does not escheat in case of an attainder and execution for felony, the maxim being, "the father to the bough, the son to the plough." In most places the tenant had the power of devising lands by will, before the statute for that purpose was made. Though the lands in Kent have now for the most part been *disgavelled* by particular statutes, the presumption is still in favour of this species of tenure until the contrary be shown.

The term *gavel-kind* is said by Lambard to be compounded of three Saxon words, *gyfe*, *eal*, *kyn*, or *omnibus cognatione proximis data.* Verstegan calls it *gavel-kind*, or give all kind, that is, to each child his part; and Taylor, in his history of *gavel-kind*, derives it from the British *gavel*, a hold or tenure, and *cenned*, *generatio* or *familia;* and so *gavel cenned* might signify *tenura generationis.*

GAVOTTA (Italian), a lively dance-tune in two-fourth time, consisting of two sections, each containing eight measures.

GAWELGUR, a strong fortress of Hindustan, in the dominions of the Nizam or ruler of Hyderabad. It stands on a high and rocky hill between the Poornah and Taptee rivers, in one of the provinces recently alienated by the Nizam to the British in aid of the funds required for the maintenance of his military contingent. The fortress consists of a citadel with an inner fort, which fronts the north, where the rock is most inaccessible; the citadel is defended by an outer fort, and both are very strongly fortified; and the ascent by the road is very long and steep, and well defended. Notwithstanding these strong defences, it was taken by the army under General Wellesley, December 14, 1803, after a siege of only two days. It was restored to the rajah on the conclusion of the peace. Gawelgur is 15 miles N.N.W. from Ellichpoor. E. Long. 77. 23., N. Lat. 21. 20.

GAY, JOHN, one of the most eminent of the secondary English poets, was a native of Devonshire, born in 1688 at Frithelstock, near Torrington, where his family had been long settled. His father dying when the future poet was only about six years of age, and leaving four children, the prospects of the family were unpromising; and John, after receiving his education at the grammar-school of Barnstaple, was put apprentice to a silk mercer in London. He disliked the employment, obtained his discharge, and embarked on a literary life, varied only by incessant efforts to obtain the patronage of the great. How he lived up to his twenty-second year is not stated. In 1710 he published his poem of *Wine*, an enumeration of the charms of the "enlivening grape," written in the grave, mock-heroic, and minutely descriptive style, which he afterwards displayed with greater power in his *Trivia*. In 1712 he was received into the household of the Duchess of Monmouth in the capacity of secretary to her Grace. Next year he published his *Rural Sports*, inscribed to Pope; and this seems to have led to a friendship between the poets uninterrupted and sincere. The superiority of Pope was freely conceded. There could be no rivalry on the part of Gay, and Pope appears to have exerted himself on every occasion to serve his friend. Gay's ambition was limited to a life of ease, fine dressing, and a luxurious table, in all of which he had marvellous success, but little contentment. In the years 1713 and 1714, besides the *Rural Sports*, he produced a comedy, *The Wife of Bath*, which was acted only three nights, *The Fan*, a poem, and the *The Shepherd's Week*, a series of six pastorals drawn from English rustic life. Pope is believed to have incited his friend to this task in order to cast ridicule on the arcadian pastorals of Ambrose Philips, who had been lavishly praised in the *Guardian* (ignoring the claims of Pope) as the first pastoral writer of the age, and the true English Theocritus. The malicious wit was completely successful, but Gay's ludicrous pictures of the English swains and their loves were found to be interesting and amusing without reference to their sarcastic origin. The poem was popular, and the author's reputation considerably advanced. In this fortunate year Gay was appointed secretary to the Earl of Clarendon, ambassador to the court of Hanover; but the death of Queen Anne, August 1, 1714, soon put an end to his hopes of permanent official employment. He then tried the drama, and produced his farce of *What d'ye Call it?* which was acted with little success in February 1714–15. In 1716 appeared his *Trivia, or the Art of Walking the Streets of London*, a poem in three books, for which he acknowledged having received several hints from Swift. It is an excellent *town* poem, containing graphic and humorous descriptions of the London of that period. In January 1716–17 the comedy of *Three Hours after Marriage* was brought on the stage, and emphatically condemned. In this piece Gay was assisted by Pope and Arbuthnot. Pope is distinctly visible in his allusions to Dennis the critic; and it is remarkable that three such men should have produced a play so dull, unnatural, and gross. In 1720 Gay collected his poems and published them by subscription, by which he is said to have realized L.1000. Secretary Craggs also presented him with some South Sea Stock; and Gay called in his friends to advise as to the investment of his riches. Erasmus Lewis, according to Johnson, advised him to intrust his money to the funds, and live upon the interest. Arbuthnot bade him intrust it to Providence, and live upon the principal; while Pope directed him, and was seconded by Swift, to purchase an annuity. This was Pope's own prudent system; but Gay, like many others who ask advice, followed none, but took his own way. He embarked all in South Sea Stock; and refusing to sell out before the bubble burst, he lost the actual principal as well as the anticipated profit. The calamity overwhelmed him; his life was despaired of; but his friends exerted themselves to cheer and succour the desponding bard. Lord Burlington entertained him for months in his princely house at Chiswick; and Pope, Arbuthnot, and the other members of the circle, were unceasing in their attentions. By the beginning of 1724 he had a new play ready, a tragedy called the *Captives*, which was patronized by the Princess (afterwards Queen) Caroline and the Prince of Wales. His next performance was the *Beggar's Opera*, written in ridicule of the Italian Opera, which for a time it drove off the English stage. Swift suggested the subject, and Pope is believed to have added some poignancy to the satirical songs; but Gay's own *bonhomie* and voluptuous style colour the whole. The play ran to the end of the season, sixty-two nights, four of which were for the benefit of the author, and produced to him the handsome sum of L.693, 13s. 6d. The same year he sold his copyright of the *Opera*, with Fifty Fables in verse, for ninety guineas. The success of *The Beggar's Opera* induced Gay to attempt a continuation of the operatic style. He wrote another piece, *Polly*, with no satirical design, as he states; but the lord chamberlain prohibited its representation. The poet then resorted to publication by subscription; his friends were again active—the Duchess of Queensberry even bearding royalty in resentment of the refusal of the license; and Gay must have cleared above L.1000 by what was deemed his oppression. The Duke of Queensberry received Gay into his house, and the duchess treated him with equal respect for his talents and character. This clever, beautiful, and eccentric woman—the idol of the poets—appears nowhere to more advantage than in her affectionate patronage of Gay, and her long-cherished regret for his loss. The poet died, after a short illness, December 4, 1732, and the Duke and Duchess of Queensberry honoured his remains with a splendid funeral and monument in Westminster Abbey. A second volume of Fables, and another opera, *Achilles*, had been written by Gay, and they were published after his death, the profits going to his sisters, two widow ladies, who inherited by the poet's death no less than L.6000. Pope and Swift—always ready to blame the court and courtiers, though far from averse to their society—have censured Mrs Howard, afterwards Countess of Suffolk, for not more zealously promoting the interests of Gay by her supposed influence with the king. One offer was made to the poet—the situation of gentleman-usher to the Princess Louisa, a child—but he declined it on account of his being, as he writes to Swift, so far advanced in life. He was only thirty-nine; but all Gay's friends seem to have treated the offer as an indignity. When the queen's establishment was made up in 1727, they expected some more important office for their favourite associate, though it is not easy to discover what appointment about the court could have been better adapted to one so easy, so natural, and helpless. Mrs Howard, it is now known, had very little influence with her royal master. The real power was in the hands of the queen, and the philosophical Caroline was content that his Majesty (who hated *bhoetry* and *bhainting*, and looked upon poets as mechanics) should possess what mistresses he pleased, provided that the state power and patronage continued with herself and Walpole. But it may be safely said, that no man could have acquired such a body of great and accomplished friends as those which rallied round Gay, and mourned his loss, without the possession of many valuable and endearing qualities. His poetry is neither high nor pure; but he had humour, a fine vein of fancy, and powers of observation and local painting which bespeak the close poetical student and the happy literary artist. (R. C—S.)

GAYAH, or Boodh Gayah, a town of Hindustan, in the British district of Behar, under the jurisdiction of the lieutenant-governor of Bengal. It was one of the most celebrated places of Hindu pilgrimage, having been the birthplace of Boodh or Buddha, one of the supposed incarnations of the Deity. Many extraordinary ceremonies are performed here by those who frequent the sacred spot. Among these many of the female pilgrims, especially widows, are in the practice of shaving their hair, and devoting themselves from that time to a life of sanctity. The whole business is under the superintendence of Brahmins, who permit any person to enter the temple and approach the idol, which is that of a man sitting cross-legged, and so very rudely carved as to indicate a very remote antiquity. The town consists of two divisions, one of which is appropriated to the priests and their attendants. The number of pilgrims resorting annually to Gayah has been estimated at 100,000, though in some years this amount has been doubled. According to a recent return, the number of houses amounts to 9165, and the population to 43,451. Distant N.W. of Calcutta 265 miles. E. Long. 85. 5., N. Lat. 24. 49.

GAYATRI, the holiest verse of the Vedas, not to be uttered to ears profane, but to be recited only mentally. It is a short prayer to the sun, identified with the supreme being, and occurs in the 10th hymn of the 4th section of the 3d ashtaká of the Sanhitá of the Rigveda—*Tat savitur varenyam bhargo devasya dhimahi dhiyo yo nah prachodayát, i.e.* "We meditate on that excellent light of the divine sun; may he illuminate our minds."—*Rigveda*, iii. 4, 10. Such is the fear of profaning this text, that copyists of the Vedas often refrain from transcribing it both in the Sanhitá and the Bháshya.—Wilson, *Vishnu Parána*, p. 122, note 13. This hymn, ascribed to Vishwámitra, is properly the only Gáyatrí; though, according to a system of the Tántrikas, a number of mystical verses bear the same name. It is usually personified as a goddess, wife of Brahmá, and metaphorical mother of the first three castes.—Rosen's *Rigvedæ Specimen*, p. 13, London, 1830. [It appears to be the feminine of some obsolete word, *gáyatra*, derivable from *gai*, "to sing."]

GAY-LUSSAC, Nicolas François, is justly reckoned among the most distinguished of the chemists and natural philosophers of the age. He was born at St Léonard (Haute-Vienne), December 6, 1778, and was educated at L'École Polytechnique, where he attracted the attention of Berthollet; and from thence he passed to L'École des Ponts et Chaussées.

The expansion of gases had long been a subject of investigation among the savans of his day; and though the young Gay-Lussac was as yet but on the threshold of the temple of science, he set his heart upon resolving the important problem. The result of his experiments was, that the difference of the proportions hitherto obtained was owing to the presence of water in the gases, and that when perfectly free from moisture they all dilate uniformly with every degree of increased heat. By further experiments on mercury he ascertained that it dilates equably from the temperature of ice (32° Fahr.) to that of boiling water (212° Fahr.), and that at the same time it increases one-third in volume.

Intimately connected with the expansion of gases was that of balloons, to which Gay-Lussac's attention was particularly directed by some observations of the natural philosopher Charles, who remarked what important experiments in magnetism, electricity, and atmospheric phenomena might be made in the higher regions of the atmosphere by means of balloons. See Aeronautics, vol. ii., p. 181.

The services which Gay-Lussac had thus rendered to science were rewarded by the general esteem of the eminent men of the day, and especially by the friendship of Alexander von Humboldt, in company with whom he made a tour through France, Switzerland, Italy, and Germany, in the years 1805 and 1806, taking magnetic observations at various stations between the latitudes of Naples and Berlin, with a view to determine the position of the magnetic equator, and its intersection with the terrestrial equator. One result, among other important discoveries, was that the great chains of mountains, and even volcanoes, have no perceptible influence on the magnetic force, and that it diminishes in proportion to the distance from the terrestrial equator.

Another important class of Gay-Lussac's experiments was in connection with the voltaic or galvanic pile. He missed, indeed, the reward promised by Napoleon for the most important discoveries obtained by means of this apparatus, the French Institute having decreed it to Sir Humphry Davy, who by its use discovered potassium and sodium, demonstrating that the two substances called potass and soda are not simple bodies, but combinations of oxygen, with a metallic base. These researches, however, the French philosopher had the merit of following up. The Institute having provided the means of constructing a battery for operations on a great scale, appointed Gay-Lussac and Thénard to preside over the experiments for which the battery was designed. In 1811 these able chemists published, in two 8vo volumes, and under the title of *Recherches physico-chimiques*, the experiments of several years. The results appear chiefly to have been the obtaining of potassium and sodium in greater proportions than those mentioned by Sir H. Davy; the decomposition of alkalies by fire at a high temperature; the separation of boron from boracic acid; the analysis of organic products by their combustion by means of chlorate of potass; and, finally, they demonstrated that sugar, starch, and wood contain nearly the same proportions of hydrogen and oxygen as water.

Gay-Lussac published his curious researches on the theory of vapours and capillary attraction; on the expansion of gases; on the nature of chloric and hydrosulphuric acids; his observations on the number and nature of metallic oxides; and his experiments on cyanogen and iodine in the *Annales de Chimie et de Physique*, which he edited in concert with Arago; *Le Bulletin de la Société Philomathique;* and *Les Mémoires de la Société d'Arcueil*, which was partly edited by Humboldt.

Few men have led such a life of scientific industry as Gay-Lussac. There is scarcely a branch of chemical or physical science to which he did not contribute some important discovery. Among these, his discovery of the general laws in the composition of bodies, particularly in the animal and vegetable kingdoms, may be considered the most distinguished. He was an able and ingenious manipulator, and it would be impossible to recapitulate in a brief memoir a tithe of his philosophical labours, and their important bearings on the progress of natural science. In 1808 he became a member of the Académie des Sciences; in 1816, professor of chemistry at the Jardin du Roi and L'École Polytechnique; and there were few learned societies in France or elsewhere of which he was not a member.

In 1831, being elected deputy for his native department, La Haute-Vienne, Gay-Lussac was called to a new sphere of duty. It would seem that he had never studied the higher questions of legislation and government, or attached himself to any political creed; but he took part in discussions relative to industrial matters, to commerce, to public instruction, and to various educational establishments. After the dissolution of the government in 1837, he was re-elected to the same office, but missed his election in 1839. Immediately after this disappointment he was elevated to the dignity of a peer of France, by an ordonnance of the king, dated March 1839.

After a long life thus devoted to the interests of science, Gay-Lussac died at his residence in the Jardin des Plantes of Paris, May 9, 1850, in the 72d year of his age. (A. F. F.)

GAZA, an ancient city of Palestine, mentioned in Gen. x. 19 as one of the border cities of the Canaanites. In the division of the land Gaza fell to the lot of Judah, and was taken by him, with the coast thereof; but its inhabitants were not exterminated, and it always appears in Scripture history as a Philistine city. Gaza occurs several times in the history of Samson, being the city of which he carried away the doors of the gate, and that in which he pulled down the temple of Dagon. It was one of the five Philistine cities which gave each a golden emerod as a trespass offering to the Lord, on account of the ark. Solomon's kingdom extended as far as Gaza; and Hezekiah smote the Philistines as far as Gaza. It was besieged by Alexander the Great after the destruction of Tyre, and taken after an obstinate defence of several months. Jonathan Maccabæus destroyed its suburbs, and Simon Maccabæus took the city itself, though not without extraordinary efforts. Alexander Jannæus besieged it in vain for twelve months, when it was betrayed into his hands. It was among the cities given by Augustus to Herod, after whose death it was united to the province of Syria. It was near Gaza, on the road from Jerusalem to that place, that Philip baptized the ennuch "of great authority under Candace queen of the Ethiopians." It lies on the road leading from Akabah to Hebron, which passes along nearly the whole length of the great Wady-el-Arabah; in N. Lat. 31. 29., E. Long. 34. 29. The port of Gaza, called *Majuma Gazæ*, was situated about 20 stadia from the city. The emperor Constantine conferred important privileges upon it, and gave it the name of Constantia. Julian took away its name and privileges, which, however, were restored by subsequent emperors. The modern town, called by the Arabs *Ghuzzeh*, is situated partly on a hill about 60 feet above the plain, and partly on the plain below. Including the suburbs, the modern town contains about 10,000 inhabitants.

GAZELLE. See index to MAMMALIA.

GAZETTE, a newspaper containing an account of such transactions and events, whether of a public or private nature, as are deemed important and interesting. The word is said to be derived from *gazzeta*, the name of a Venetian coin, which was the price of the first newspaper printed at Venice, and came to be applied to the newspaper itself.

The *London Gazette* was first printed at Oxford in 1665 by the university printer, and the first twenty-three numbers were called *The Oxford Gazette.* These numbers were reprinted in London, and the publication was then continued in the metropolis. *The London Gazette* was originally published twice a-week, and comprized two pages of small folio, containing scraps of foreign intelligence, shipping news, appointments of sheriffs, circuits of the judges, orders in council, notices of non-payment of duties, and such like. At the end of two years a few advertisements crept in of goods lost, run-away servants, offenders, and then of lotteries of books, books for sale, and books published, and later the puffs of quack medicines. For the first twenty years the publication continued with little change in matter or form; but in the beginning of the eighteenth century we find extra numbers, the origin of the "Gazette extraordinary," published on the arrival of mails from Holland, and the gazettes extended in size to contain *in extenso* the despatches from our military and naval officers.

The original use of the gazette is continued to this day. It is the means by which the government formally promulgates all state intelligence, all matters of public interest affecting the royal family, orders in council, proclamations, addresses to the throne, offers of pardon, and military despatches. In it the ecclesiastical, civil, and military appointments are also published, or as it is called "gazetted;" but this does not appear to be governed by any uniform rule, for the appointment of a judge of the superior courts is not gazetted, while the mere nomination of a country solicitor to administer an oath, or to do some other formal act, does not fail to be fully recorded.

The gazette, which so long filled only two pages, now usually extends to thirty or forty. This great addition of space chiefly arises from the number of notices connected with trade and commerce, and required by enactments passed from time to time rendering insertion in the *London Gazette* a legal formality. All fiats, meetings of creditors, dividends, and certificates are inserted under the bankruptcy law, and under the insolvency law all declarations of insolvency, and applications for protection to the insolvency court; dissolutions of partnership, returns of the prices of corn, sugar, &c. are also gazetted. Further insertion is required of notices and decrees of the courts of chancery and exchequer, legal notices of sales under orders of the law courts, notices to the heirs of deceased persons, of the meetings of public companies, &c.

The office of gazette writer was formerly an appointment of some importance, but it has recently been placed upon an altered footing, and an officer who is jointly "editor, manager, and publisher," is now solely responsible for the conduct of the publication. He is appointed by the home and foreign secretaries alternately.

In 1831 the receipts for advertising notices and sale of gazettes was L.15,083, and the cost of publishing L.7807, the balance or profit being divided between the home office and the foreign office, and applied towards the expenses of those departments. In 1848 the receipts were L.17,182, and the expenses L.6195, the balance being divided as already described. But from this year a new arrangement commenced, and the receipts were paid into the exchequer to the public account, and the expenses defrayed by an annual parliamentary grant. The advertisements are paid for on a fixed scale; and the charge to the public for the gazette is—not exceeding four pages 4d., for every additional eight pages 8d., for thirty-two or more pages 2s. 8d. The gazette is subjected to the same postal regulations as an ordinary newspaper.

A gazette, called the *Edinburgh Gazette*, is published in Edinburgh upon precisely the same principles as the *London Gazette*. In 1853 it was proposed to combine these two publications, to prevent the necessity of inserting certain notices and advertisements in both, and a bill was introduced in the House of Commons to effect this, but was not proceeded with. Up to 1848 the profits of the *Edinburgh Gazette* were in the hands of private persons. Since then, by an arrangement with these interests, the proceeds have been paid into the exchequer, by which the charge is now borne. In 1849 the receipts of the publication were L.3190, and the expenses L.1325.

At Dublin a similar publication—the *Dublin Gazette*—exists. It does not appear that the receipts of this publication have been sufficient to cover the expenses. In 1849 they were L.1256, and the outlay L.1519.

Government publish also twice a-week a *Police Gazette*, under the superintendence of the chief police magistrate (Bow Street Court). This publication contains information upon aggravated offences, stolen property, escaped thieves and suspected persons, and lists of deserters from the army, navy, and militia. It is circulated gratuitously to the police, and passed free of postage. It may be purchased at 1d. per number. (S. R.)

GAZTELUGACHE, an island of Spain, on the coast of Biscaya, to which it is united by two very elevated bridges to the S.W. of Cape Machichaco, in 43. 29. N. Lat. It is a rugged hill, or rather an extraordinary huge rock, appearing as if in the act of falling into the sea. On its summit stands the church of the Decapitation of St John the Baptist, one of the two parish churches of the village of San Pelayo de Baquio, in the jurisdiction of Bermeo. In earlier times it was a monastery of the Templars. It is reached by a flight of 370 steps, and has long been a celebrated sanctuary for the Biscayans, as well as for sailors in distress.

GED, William, the inventor of the art of stereotyping, was born at Edinburgh about the beginning of the eighteenth century. In 1725 he first put in practice the art which he had discovered; and some years later he entered into a partnership with a London capitalist, with a view to employing it on a great scale. The partnership, however, turned out very ill; and Ged, broken-hearted at his want of success, died at London in 1749. The only books which he produced on the plan of stereotyping were two prayer-books for the university of Cambridge, and an edition of Sallust.

GEDDES, Alexander, an eminent Catholic divine, was born in 1737 at Ruthven, in Banffshire, in the north of Scotland. His parents were of humble rank, and unable out of their own resources to educate their son. The kindness of a rich neighbour supplied the means; and young Geddes, after a seven years' course at the Roman Catholic seminary of Scalan, was sent to the Scottish College at Paris, where he made great progress in theology, and mastered the most important of the modern tongues. On his return to Scotland he became private chaplain to Lord Traquair, a Catholic nobleman in Peeblesshire, and in 1769 priest to the congregation of Auchinhalrig in his native county. He here gained a very strong hold over the affections of his people, by the completeness of his self-devotion to their welfare. Now it was that the idea of a new translation of the Bible adapted for the Catholics of England occurred to him; but during his whole stay at Auchinhalrig, his straitened means prevented him from procuring the needful books. In 1779 he went to settle in London, with a view to carrying out this design, taking with him the good opinion of his people, and the degree of LL.D. from the university of Aberdeen, which, since the Reformation, had never bestowed a similar honour on any Catholic. He had there the good fortune to make the acquaintance of Lord Petre, who supplied him with the necessary books, and a handsome allowance till his task should be completed. With this assistance he began his work; and in 1780 published a prospectus of it, which bore that the Vulgate was to be the basis of the new version. Finding, however, that the Vulgate was in many places inaccurate, he changed his plan, and resolved to translate directly from the Hebrew and Greek originals. Everything that hard toil could do to make this great undertaking as complete as possible was done; and in 1786 Geddes published a conspectus of his new plan, with a specimen of the work, and afterwards a "General Answer to the Queries, Counsels, and Criticisms" which these called forth. Despite his indefatigable exertions, he was not able to publish the results of his labours till the year 1792, when he gave to the world the first volume of his version under the title of "The Holy Bible, or the Books accounted sacred by the Jews and Christians, otherwise called the Books of the Old and New Covenants, faithfully translated from corrected texts of the originals, with various readings, explanatory notes, and critical remarks." Next year appeared the second volume, which brought down the work to the end of the historical books; and in 1800 the third, which contained his critique on the Pentateuch. This was the last volume that he was destined to publish. In 1802, while engaged on a translation of the Psalms, he was cut off rather suddenly in the sixty-fifth year of his age. His version of the Psalms, which he completed as far as the 118th, was published in 1807.

Geddes's theological opinions were on many points so different from those then current in England, that for some time he stood quite alone, an object of equal alarm and hostility to his own church and all the Protestant denominations. The former, indeed, set the example of the persecution, to which he was for a considerable period subjected. His independence of thought and action was the cause of his leaving Auchinhalrig; and after he published his version of the Bible, a majority of the Catholic bishops in England forbade its use in their sees, while the apostolic vicar of the London district interdicted him from officiating as priest. This is hardly to be wondered at, as Geddes denied not only many of the tenets of the Romish Church, but even the authority of the pope. He denied the inspiration of the Scriptures, the divine legation of Moses (whose miracles he either rejected altogether, or tried to explain away according to natural laws), and pronounced the Mosaic account of the creation "A most beautiful mythos or philosophical fiction, contrived with great wisdom, and dressed up in the garb of real history." This view will be seen at a glance to identify Geddes with the school of German Rationalists, the leaders of which, Paulus and Eichhorn, were his personal friends. It is no wonder that accusations of infidelity, and an ill-masked desire to destroy the authority of Scripture, were heaped upon him from all quarters. To dissipate these charges, he published an "Address," in which he proclaimed himself "a sincere though unworthy disciple of Christ," and denounced those as the real enemies of religion "who seek to support her on rotten props, which moulder away at the first touch of reason and leave the fabric in the dust." Despite these assurances, however, Geddes continued to be looked upon as a dangerous champion of infidelity; and his works, if they did nothing more, at least directed the thoughts of men to establishing the principles of Christianity on a surer basis than before. The credit refused to his honesty and ability at home was readily conceded by his German friends, Paulus and Eichhorn, the latter of whom declared Geddes to be the only English theological writer of that day by whose opinion he would consent to be judged. The foregoing facts have been taken from the "Life of Geddes," by Dr Mason Good, London, 1803. The biographer gives a very detailed list, with specimens of Geddes's compositions in all the languages with which he was acquainted, and a full analysis of his translation of the Bible. This work he criticises as "for the most part plain and perspicuous, conveying the sense of the original in its native simplicity. But his language is occasionally unequal, and strongly partakes of the alternations of his own physical constitution; in consequence of which, in the midst of a passage most exquisitely rendered in the main, we are at times surprised with scholastic and extraneous expressions, or disgusted with intolerable vulgarisms." The "Life of Geddes" also contains some interesting specimens of the Latin correspondence carried on for many years between the Scottish philosopher and his most eminent friends and fellow-labourers in the same field in Germany.

GEELONG, a town of South Australia, Victoria colony, Grant county, at the head of Geelong harbour, the western arm of the bay of Port Philip, 40 miles S.W. of Melbourne. Since the discovery in 1851 of the gold fields at Ballarat, 40 miles N.N.W. of Geelong, this town has rapidly risen into importance. It is situated in a very pleasant and fertile district, adorned with numerous cottages and gardens, and the climate is mild and salubrious. The town is built on the harbour of Corio, by means of which a great trade is carried on. Large vessels discharge their cargoes into lighters six miles below the town. Pop. (1853) about 20,000.

GEFLE, a seaport-town of Sweden, capital of the län or province of Gefleborg, situated at the mouth of the Gefle river in the gulf of Bothnia, 92 miles N.N.W. of Stockholm. The river is here separated into three branches, forming two islands, on which, as well as on either bank, the town is built. It is the seat of a governor-general, and has a castle, a town-hall, one of the finest in the country, a gymnasium, hospital, orphan asylum, &c. The chief manufactures are tobacco, linen, sailcloth, leather, and sugar. It has a good harbour, defended by a long jetty, and carries on an extensive export trade in iron, timber, pitch, tar, &c. Pop. 9000. The province of Gefleborg has an area of 7531 square miles, and a population (1850) of 120,158.

GEHENNA, a term used in the New Testament to signify hell, and which is derived from the Hebrew *Ge-hinnom*, *i.e.* the valley of Hinnom. In this valley, which lies on the north side of Jerusalem, below Mount Zion, there was a place named Tophet, where, under idolatrous kings, children were immolated in honour of the god Moloch. When king Josiah overthrew that idolatry, he made this valley the receptacle for all the filth and carcasses in the city, and a fire was kept constantly burning to consume the combustible portions of the refuse deposited there; on which account the Jews, as they had no proper word in their language to signify "hell," made use of *gehinnom* as an equivalent term.

GELA, a city on a river of the same name on the south coast of Sicily, founded by the Rhodians from Lindus in conjunction with a colony of Cretans, about the year 690 B.C., very near the site of the modern Terranuova on the Fiume di Terranuova, betweeen Agrigentum and Camarina. Gela soon rose to great wealth and power, and sent out a colony in 582 B.C. to found Agrigentum, which soon rose to greater eminence than the mother city. The most important of its rulers were Cleander, who subverted the oligarchical form of government, and raised himself to despotic power (505–498 B.C.); Hippocrates, his brother, who received the sovereign authority from him, and raised Gela to its highest pitch of eminence (498–491 B.C.); Gelon, who immediately succeeded Hippocrates, and rapidly pursued the same career of aggrandisement, till in 485 B.C. he succeeded in making himself master of Syracuse itself, to which he transferred the seat of government, and thus caused the commencement of the decline of his native Gela; and Hiero, brother of Gelon, whom he succeeded in the sovereignty (478 B.C.) After this time the place gradually fell into decay, and in the time of Augustus was uninhabited.

Gela was the birthplace of Apollodorus, a comic poet of note; and was the place of Æschylus's death, 456 B.C.

GELASIUS, the name of two Roman pontiffs, the first of whom came to the papal throne in 492. He took part in the conflict then going on between the Greek and Latin Churches, but with no particular result. He also wrote some theological works, which have been partly preserved in the *Bibliotheca Maxima Patrium* of Lyons.

The second Gelasius became pope in 1118. After suffering many hardships and indignities from the partizans of the emperors of Germany, then at war with the popes, he fled from Rome, and finally retired to Rheims in France, where he maintained a sort of semblance of his ancient authority. He died in 1119.

GELATINE, or JELLY, an animal product which is extracted by long-continued boiling in water from all the hard and solid parts, such as the skin, cartilages, bones, ligaments, tendons, membranes, and muscles. By the slow evaporation of the water which thus holds it in solution, the gelatine may be obtained in a state of purity, when it appears as a hard, brittle, semi-transparent substance, which breaks with a glassy fracture. One of the most striking characteristics of gelatine is the property of forming a tremulous jelly when its solution in boiling water cools, with that of liquefying again on the application of heat. These alternate solutions and desiccations may be repeated for any number of times without changing its chemical constitution. Isinglass, glue, and size are various forms of gelatine, the first being this substance in a state of comparative purity. Solid gelatine undergoes no change if it be kept perfectly dry; but in the form of solution or of jelly it putrefies rapidly. Tannin added to a solution of gelatine occasions a copious white precipitate. This is a compound of tannin and gelatine, which collects into an elastic adhesive mass, that soon dries in the air, and forms a brittle resinous-like substance, which is perfectly insoluble in water, and not susceptible of putrefaction. It is this action of tannin upon gelatine that is the foundation of the art of tanning leather. The ultimate components of gelatine are 47·8 carbon, 7·9 hydrogen, 16·9 nitrogen, 27·4 oxygen.

Gelatine is insoluble in alcohol, but when already in solution in water it is not precipitated by that fluid. Acids dissolve it with great facility, even when much diluted, especially when aided by heat. The nitric acid effects its decomposition, during which nitrogen, and then nitrous gas, are disengaged in considerable quantities; and oxalic and malic acids are evolved, and may be obtained from the residuum. Sulphuric acid, with the assistance of heat, partly converts it into a substance resembling sugar. Chlorine combines with gelatine, forming a white substance, which assumes the form of filaments. The pure liquid alkalies dissolve gelatine very readily. The solution is a brown viscid substance, which possesses none of the properties of soap, and is not precipitated by acids. This property of remaining dissolved after acids are added to the alkaline solution, distinguishes gelatine from albumen, fibrin, and other animal products, and is therefore a valuable mode of discriminating its presence, and of separating it from them in analysis. It is precipitated by several of the metallic salts and oxides, but not so unequivocally as to afford satisfactory tests of its presence.

Gelatine is a nutritious article of food, and is very largely used as such; but as it cannot yield albumen, fibrin, or caseine, animals fed solely on gelatine rapidly lose flesh. It is much employed in confectionary, for jellies, jujubes, &c.; and in the form of thin sheets richly coloured with beet-juice, spinach-juice, or other substances, it is applied, as an elegant substitute for paper, to a variety of ornamental purposes.

GELDERLAND. See GUELDERLAND.

GELL, SIR WILLIAM, a distinguished classical scholar and antiquarian, was born in 1777. After the usual preliminary education, he was entered of Emmanuel College, Cambridge, of which he afterwards became a fellow. About the beginning of the present century he was sent on a diplomatic mission to Greece; on his return from which, in 1803, he was knighted. In the following year he published his *Topography of Troy and its Vicinity, illustrated and explained by drawings and descriptions.* He had only spent three days in the actual survey of this classic spot; but the critics were at first loud in praise of the ability, research, and correctness of his work. A more careful scrutiny, however, caused them to modify their verdicts considerably. Lord Byron who had at first praised the book, afterwards felt more inclined to condemn it. In his *English Bards* that poet had said—

> Of Dardan tours let dilettanti tell;
> I leave topography to rapid Gell.

The term *rapid* was a substitute for *classic*, which had been the original epithet. Some of his other works were perhaps chargeable with the same fault, such as his *Geography and Antiquities of Ithaca.* An exception, however, must be made in favour of his interesting *Pompeiana, or Observations on the Topography, Edifices, and Ornaments of Pompeii;* in which he was assisted by Mr J. P. Gandy.

Gell's noble and disinterested behaviour during the trial of Queen Caroline, and his manly courage in facing and braving the frowns of the great who took part with the regent at that time, exhibit his moral character in a very favourable light. The queen showed her sense of his cooperation in her defence by appointing him one of her chamberlains in 1820. He suffered severely from gout during the latter years of his life; and died at Naples in 1836.

GELLERT, CHRISTIAN FURCHTEGOTT, a distinguished German author, was born in 1715, at Haynichen, near Freiberg in Saxony. He was educated at the university of Leipsic, where, in his thirtieth year, he was appointed to the chair of belles-lettres,—a position which he occupied till his death in 1769. His principal works are his *Fabeln* and *Erzählung*, and *Sacred Odes and Songs*, both of which were immensely popular in Germany during their author's lifetime; while the former, till a recent period, held its place as a text-book in nearly all the primary schools of Germany. Not a little of Gellert's fame is due to the time when he lived and wrote. Such a German literature as there was at the time of his appearance, was groaning under the yoke of the pedant Gottsched and his school. A band of high-spirited youths, of whom Gellert was one, resolved to free themselves from these hereditary and conventional trammels, and began that revolution which was finally consummated by Schiller and Göethe. Gellert's share in the attempt was enhanced by the excellence of his personal character, his gentle piety, and his singular knack of gaining the reverence and love of young people. Part of his influence was also doubtless attributable to his position as a professor, and to his eloquent lectures on the poetry of Germany. His collective works form part of the *Karlsruher Deutscher Classiker*, 1823–26. There are some interesting notices of Gellert in Göethe's *Dichtung and Wahrheit.* His life has been twice written; first by J. A. Cramer, Leipzig 1774; and more recently by Döring, Leipzig, 1833.

GELLIUS, AULUS (sometimes, though incorrectly, called AGELLIUS), author of the *Noctes Atticæ*, was born in the course of the second century of the Christian era, and died about A.D. 180. Little or nothing is known of his personal history beyond incidental notices in his own book. From these he seems to have been born of a good family at Rome; to have travelled much, especially in Greece; to have enjoyed the tuition and personal friendship of the most eminent philosophers of that day; and, being possessed of independent means, to have spent his life in a sort of literary dilettanteism. His only work, the *Noctes Atticæ*, takes its name from the fact of its having been composed during the long nights of a winter which the author spent in Attica. In the preface he states that he had no other object in view in writing it than to while away the time in amusing his children. He had been in the habit of keeping an "Adversaria," or commonplace-book, in which he jotted down everything of unusual interest that he heard in conversation or read in books. The contents of this scrap-book he redacted with some slight changes of form into the work through which his name has been preserved. This fact sufficiently accounts for the very miscellaneous nature of the topics embraced in the book, which comprise essays on grammar, geometry, and philosophy, besides scraps of history and poetry, anecdotes, and a good deal of discussional matter. The work, which is utterly devoid of sequence or arrangement, is divided into twenty books. All these have come down to us except the eighth, of which nothing remains but the index. The work is on the whole a very useful one, as it throws light on many subjects which must otherwise have remained for ever a mystery. The style, though for the most part sufficiently clear, is disfigured by that affectation of archaism which was carried to such ridiculous extremes by Apuleius. The *editio principo* of Aulus Gellius appeared at Rome in 1469, and was speedily followed by many others in various cities of Italy, especially Venice. The best edition that has yet appeared is that of James Gronovius, Leyden, 1706; which is unquestionably superior to the recent edition of Lion, Gottingen, 1824–25. Aulus Gellius has been translated into English by Beloe, Lond., 1795; into French by the Abbé de Verteuil, Paris, 1776–89; and by Victor Verger, Paris, 1820–30; and partly into German by Walterstern, Lemg., 1785.

GELNHAUSEN, a town of Hesse-Cassel, province of Hanau, on the right bank of the Kinzig, 12 miles E.N.E. of the town of Hanau. It was formerly an imperial city, and was for some time the residence of the emperor Frederick Barbarossa. The ruins of his palace still exist on an island in the river. Being on the highroad from Frankfort to Fulda and Eisenach, it is a place of considerable trade. Pop. 4000.

GELON, tyrant of Gela and afterwards of Syracuse, raised himself to the supreme power in his native city of Gela by his military talents. The quarrels between the aristocracy and the plebs of Syracuse gave him an opportunity of interfering in the affairs of that city, and he so managed among the disputants that he ended by becoming its "tyrannus." He used his power so discreetly that Syracuse attained a degree of wealth, influence, and prosperity which reconciled the people to their bondage. The great event in Gelon's subsequent history was his defeat of the Carthaginians under Hamilcar at Panormus, on the same day that the Greeks defeated Xerxes at Salamis, B.C. 480. After Gelon had thus established his power, he made a show of resigning it; but his proposal was rejected by the multitude, and he reigned without opposition till his death, 478 B.C. His memory was held in such respect that, 150 years after his death, when Timoleon was erasing from Sicily every vestige of the tyrants that had once reigned there, he spared the statues of Gelon. (See SYRACUSE, and CARTHAGE.)

GEM, a common appellation for all precious stones, and particularly for those which are employed in jewellery. Brilliancy of lustre, richness of hue, and the most perfect transparency, are the desiderata of this class of minerals;

and the value of those specimens in which such characters are combined is enhanced according to their size, in an extremely rapid ratio. At the head of the gems stands the diamond, which, for brilliancy of lustre, or *water*, as it is termed, has not a rival. It is chiefly found in certain parts of Hindustan and Brazil, where it occurs in alluvial soil, or in conglomerate of the most recent formation. (See Diamond.) The oriental ruby, when perfect in transparency and colour, and of considerable size, vies with the diamond in value. Its most noted locality is the Capellan Mountains, near Syrian, in the kingdom of Ava. Next in order is the sapphire, which varies from a rich dark blue to a very slight tinge of the same colour, sometimes presents distinct colours in the same specimen, and is frequently transparent and colourless. It is met with in considerably larger masses than the preceding, and is found in Ava and Ceylon. The peculiar rich green colour of the emerald is well known. No gem is more frequently made mention of in sacred history, and none even at the present day stands in higher estimation among the crowned heads of the East. The aquamarine of lapidaries is, mineralogically speaking, a pale-blue variety of the same species, though one of very inferior value. Topazes occur under an infinity of forms, and are found in most quarters of the globe. From the changes which they undergo when exposed to heat, besides the fine colours they present naturally, topazes are peculiarly adapted to the purposes of the lapidary. The richest-coloured garnets are the production of Ceylon and Greenland. Chrysolites of a brilliant pale-green colour are brought to Great Britain from Constantinople; hyacinths of a deep red from Ceylon; and tourmalines of a great variety of hues from all parts of the world. The opal, and many varieties of quartz, as the amethyst, onyx, sarde, catseye, and agate, are also occasionally included under the general denomination of gem.

Generally speaking, the different species of precious stones occur in small masses. All of them are found in a crystalline state, and present the peculiar forms which nature has assigned them. Many of these forms are singularly beautiful; and their variety, particularly in the diamond and topaz species, is as great as any other class of the mineral kingdom affords. It is not, however, under these symmetrical forms that gems are most commonly found. Most of them are the productions of India, Ceylon, Pegu, and Brazil, where, having been washed from their matrix in some of the primitive ranges, they are collected, in a rolled and rubbed state, in the channels of the rivers. Every trace of their original form is thus frequently lost; and, indeed, fine stones rarely come through the hands of Indian lapidaries without receiving further abrasion or cutting. This circumstance of their so rarely presenting distinct forms renders the peculiar hardness of this class of stones a most important characteristic, and one, whatever be their external shape or appearance, which can never be mistaken. By this means, too, the real stone is easily distinguished from the factitious, which is occasionally made to bear so close a similitude that an unpractised eye finds it almost impossible to detect the difference. See Mineralogy.

GEMARA, the second part of the *Talmud*. It is a 'commentary' on the *mishna* or text. See Talmud.

GEMINI (the Twins), the third constellation in the zodiac. It is referred by the Greeks not only to the fable of Castor and Pollux, but also to those of Hercules and Apollo, Triptolemus and Iasion, Amphion and Zethus, &c. The constellation derives its name from two remarkable stars to which the names *Castor* (or α^2 Geminorum) and *Pollux* (or β Geminorum) are given. These two stars may be easily found by drawing a straight line through the belt of Orion and the two bright stars the line of which cuts through the belt. This line protracted upwards very nearly passes through the two stars of Gemini. They may also be recognised by being about midway between Aldebaran and Regulus; and should Orion and Ursa Major be seen at the same time, then Castor and Pollux on the one side, and Capella on the other, are conspicuous boundaries of the intermediate space. On Jan. 1, 1856, the right ascension of Castor was $7^h\ 25^m\ 24^s{\cdot}357$, with an annual variation of $+\ 3^s{\cdot}8433$; and his declination was $32^\circ\ 11'\ 58''{\cdot}73$ N., with an annual variation of $-7''{\cdot}38$. On the same day the right ascension of Pollux was $7^h\ 36^m\ 29^s{\cdot}907$, with an annual variation of $+3^s{\cdot}6822$; and his declination was $28^\circ\ 22'\ 11''{\cdot}59$ N., with an annual variation of $-8''{\cdot}258$. Their respective magnitudes were 2·1 and 1·2.

GEMINIANI, Francesco, a celebrated violinist, born at Lucca about 1666. He received lessons in music from Alessandro Scarlatti, and studied the violin under Lunati, and lastly under Corelli. In 1714 he arrived in London, where his performance and compositions attracted much attention. He was taken under the special protection of the Earl of Essex. After visiting Paris, and residing there for some time, he returned to England in 1755. In 1761 he went to Dublin, where he was by a servant robbed of a musical manuscript on which he had bestowed much time and labour. His vexation at this loss is said to have hastened his death, which took place at Dublin on 17th September 1762. He appears to have been a first-rate violinist, but most of his compositions are dry, and deficient in melody. His *Art of Playing the Violin* is a good work of its kind, but his *Guida Armonica* is a miserable production. He published a number of solos for the violin; three sets of violin concertos; twelve violin trios; *The Art of Accompaniment on the Harpsichord, Organ, &c.*; *Lessons for the Harpsichord*; and some other works. His musical opinions had no foundation in truth or principle. "One day he would set up French music against all other; the next, English, Scotch, Irish—anything but the best compositions of Italy or Handel." He then became a dishonest dealer in pictures—"imposing upon grosser ignorance with false names, and passing off copies for originals." (G. F. G.)

GEMISTUS, or **Georgius Pletho**, one of the later and most celebrated Byzantine writers, lived during the end of the fourteenth and beginning of the fifteenth century. His native place was probably Constantinople, though he spent most of his time in the Peloponnesus. In 1426 he held a high office under Manuel Palæologus the emperor; and was one of the deputies of the Greek Church that were present at the Council of Florence held in 1438 for the purpose of effecting a union between the Latin and the Greek Churches. Gemistus was still more famous as a philosopher than as a theologian. Being disgusted with scholastic philosophy he made Plato the subject of earnest study; and henceforth the propagation of the Platonic philosophy became his chief aim. Having been introduced to Cosmo de' Medici during his stay at Florence, he persuaded this distinguished man of the superiority of the system of Plato over that of Aristotle, and became the leader of a new school of philosophy in the West. Gemistus wrote an immense number of scientific works, dissertations, treatises, compilations on divinity, history, geography, philosophy, and miscellaneous subjects. Several of them have been printed.

GEMONIÆ Scalæ, or *Gemonii Gradus*, in ancient Rome, steps on the Aventine Hill, leading to the Tiber, to which the bodies of criminals were dragged with hooks after execution, to be cast into the river

GENALGUACIL, a secular town of Spain, in the province of Granada, and bishopric of Málaga. It is situated south of Ronda and of Benestepar, on the right bank of the Genal, eight miles from Casares, four from Jubrique, and is surrounded with hills and vineyards. The site is cheerful and picturesque, but the town is not well built, the houses being generally small, and the streets ill-paved, uneven, and dirty. The parish church is modern, handsome, and consists of three naves; besides, there are a town-house, a primary school, and a miserable prison. There are also mineral springs; brick and tile works; many distilleries; several flour and oil mills; and a good trade in wine. The population is nearly 2000.

GENDARMERIE, or men-at-arms, have existed in France, with various modifications, since the days of chivalry. At that time they were furnished by the fiefs, and, armed cap-a-pie, marched in the train of the knights and esquires. When the English were driven out of France by Charles VII., companies of gendarmes were distributed throughout the whole extent of the kingdom, and contributed powerfully to the re-establishment of internal order and tranquillity. At this time they enjoyed much consideration and many privileges, of which they were gradually deprived by the successive changes in the regular army, until in the time of the Grand Monarque they came to be looked upon as nothing but an unusually fine cavalry corps. Shortly before the French revolution, the gendarmerie had ceased to exist as a separate organization, having been merged in the maréchaussée. The Constituent Assembly again changed their name into "gendarmerie nationale." The history of the gendarmerie, which, up to this date, is a very difficult and complicated one, is fully treated by a French writer M. Tenaille-Champton. In modern parlance the term is employed to denote a military police, whose duties are to watch over the public safety, maintain order, and enforce the execution of the laws. The gendarmes also furnish patrols, examine the passports of travellers, arrest criminals, and otherwise ensure the general tranquillity. They consist of two classes, horse and foot, which are called respectively gendarmes-à-cheval and gendarmes-à-pied. The men themselves consist for the most part of deserving soldiers of the regular army, who for good conduct have been drafted into this service, where they enjoy certain privileges, and a much higher rate of pay than the soldiers of the line. They are held, however, to form part of the army, and in cases of extreme necessity are liable to be called into active service. The gendarmerie have always been noted for their faithful adherence to the government under which they have served; and in the revolutions and tumults of which Paris has been the theatre during the last twenty-five years, they have always signalized themselves by their heroic devotion to the cause they had sworn to defend. During that period their numbers have varied from 12,000 to 25,000.

GENDER. See Grammar, § *Of the Noun.*

GENEALOGY (γενεολογία: γένος *race*, and λόγος *account*), an enumeration of a series of ancestors, or a summary account of the relations and alliances of a person or family, both in the direct and collateral lines. A genealogy or lineage is frequently drawn out under the figure of a tree, with its root, stem, and branches, and the genealogical degrees are usually represented in circles or parallelograms, ranged over, under, and beside each other.

No nation was more careful to frame and preserve its genealogical tables than Israel. Their sacred writings contain genealogies which extend through a period of more than 3500 years, from the creation of Adam to the captivity of Judah. Indeed, it appears from the books of Ezra and Nehemiah that the same carefulness in this matter was observed *after* the captivity; see Ezra, ii. 62. The division of the whole Hebrew nation into tribes, and the allotment to each tribe of a specified portion of the land of Canaan as an inalienable possession, rendered it indispensable that they should keep genealogical tables. But it was not this alone that made the Jews so anxious to preserve their pedigrees; for the voice of prophecy had declared that the promised Messiah should be of the seed of Abraham, of the posterity of Isaac, of the sons of Jacob, of the tribe of Judah, and of the family of David.

The Rabbins affirm that after the Captivity the Jews were most careful in keeping their pedigrees (*Babyl. Gemar. Gloss.* fol. xiv. 2). Josephus (*De Vita sua*, p. 998, D) states that he traced his own descent from the tribe of Levi by *public registers.* And he informs us, that however dispersed and depressed his nation were, they never neglected to have exact genealogical tables prepared from the authentic documents which were kept at Jerusalem; and that in all their sufferings they were careful to preserve those tables, and to have them renewed from time to time. Since, however, the period of their destruction as a nation by the Romans, all their tables of descent seem to be lost, and now they are utterly unable to trace the pedigree of any one Israelite who might lay claim to be of that line from which their still expected Messiah is to arise.

GENERAL, in the British army, the highest *ordinary* rank—he who commands a brigade, a division, a corps, or an army. See Army.

General is also used for the chief of an order of monks, or of all the houses and congregations established under the same rule.

GENERAL ASSEMBLY. See Presbyterianism.

GENERALISSIMO, a military title, more especially among the French, equivalent to that of commander-in-chief. We are told by Balzac that the title of generalissimo was first assumed by Cardinal Richelieu, on the occasion of his leading a French army into Italy.

GENERATING Line, or Figure, in *Geometry*, a line or figure which by its motion of revolution produces any other figure, plane, or solid.

GENERATOR, in *Music*, signifies the principal or fundamental sound by which certain harmonic sounds are produced. See Music.

GENESIS, the first book of the Old Testament, containing the history of the creation, and the lives of the first patriarchs. See Pentateuch; Scripture; Bible; and Dissertation Third, vol. i. of this work.

Genesis, in *Geometry*, the formation of a line, plane, or solid by the motion of a point, line, or surface.

GENESIUS, Josephus, or Josephus Byzantinus, a Byzantine writer who lived in the middle of the tenth century, is the author of a Greek history which he wrote by order of the emperor Constantine VII. This history begins with the year 813 A.D., is entitled Βασιλειῶν Βιβλία Δ, and embraces the reigns of Leo V. the Armenian, Michael II. the Stammerer, Theophilus, Michael III., and Basil I. the Macedonian, who died in 886. The work of Genesius is considered of importance as containing the events of a period of Byzantine history which is elsewhere very scantily found, though it is but a poor compilation. At Leipzig, a MS. of this work was discovered in the sixteenth century, and attracted the attention of scholars. The first edition of Genesius was published at Venice in 1733, folio, with the title, *Josephi Genesii de Rebus Constantinopolitanis*, &c. Libri IV., with a Latin translation by Bergler. The best edition, however, is by Lachmann, in the Bonn edition of the Byzantines, 8vo, 1834.

Cave, *Hist. Lit.*; Fabric., *Bibl. Græc.*, vol. vii.; Hamberger, *Nachrichten von den vornehmsten Schriftstellern*, vol. iii.

GENETHLIACI (γενέθλη, *birth*), a name given by the ancients to those who pretended to foretell what should befall a man by means of the stars which presided at his nativity. They were also called Chaldæi or Babylonii, from the country where their science was first developed; sometimes *astronomi*, *astrologi*, or *planetarii*, because they observed the stars; and likewise *mathematici*, from their employing diagrams such as were used by geometricians. Edicts at various times were issued against the astrologers of ancient Rome; yet notwithstanding the rigour of the penal enactments by which they were denounced, they continued to maintain their popularity, and were never altogether expelled from the city. Hence Tacitus speaks of them as "*genus hominum quod in civitate nostra et vetabitur semper et retinebitur*."

GENEVA (Fr. *Genève*, Ger. *Genf*, Ital. *Ginevra*), the most populous and industrious city of Switzerland, capital of the canton of the same name, stands on the Rhone, at the western extremity of the Lake of Geneva, in Lat. 46. 12. N., Long. 6. 9. 30. E. It is divided into three portions by the river, part being on an island and part on either bank. The largest portion stands on the left bank of the river, and is built partly on an eminence rising to nearly 100 feet above the level of the lake. It consists almost entirely of the large and handsome mansions of the burgher aristocracy. On the right bank is the Quartier St Gervais, or lower town, the seat of the trade and commerce. The streets are here narrow and the houses lofty, something in the style of the old town of Edinburgh. The island is upwards of a furlong in length by about 200 feet in breadth, and is connected with the other portions of the town by several bridges. Geneva has been much improved within the last quarter of a century. An entirely new quarter has started up on the right bank of the Rhone, called Quarter des Bergues, displaying a handsome front of tall houses, among which is the Hôtel des Bergues, and lined with a broad quay towards the lake. On the opposite bank the unsightly houses that lined the margin of the lake have been repaired and beautified, and a broad belt of land has been gained from the water and formed into a quay. This is connected with the Quai des Bergues by means of two bridges thrown across the river, and united with a small island planted with trees, and containing a bronze statue of Rousseau. Geneva is surrounded landward by ramparts and bastions, erected in the middle of the last century, but of little use as fortifications, the city being commanded by some adjacent heights. The principal public building is the cathedral or church of St Pierre, an interesting specimen of Gothic architecture of the eleventh century. Its effect, however, has been injured by the addition of a fine Corinthian portico. This church contains monuments of Agrippa d'Aubigny, the friend of Henri IV., and of the Count Henri de Rohan, a leader of the French revolution in the reign of Louis XIII. The town-hall is an old and massive-looking building. The Musée Rath, so named from its founder General Rath, is a neat edifice, containing a collection of paintings and other works of art, chiefly by native artists. The museum of natural history contains principally native productions of Switzerland, and is chiefly interesting as having the geological collections of Saussure, Brongniart, and Decandolle, and the collections of M. Necker. The house in which Calvin is said to have lived and died is still pointed out in the Rue des Chanoines, and also the house in which J. J. Rousseau was born. The general hospital is an extensive and spacious building. The academy or university founded by Calvin has faculties of theology, law, science, and belles lettres, and forty professors. The public library attached to it contains about 50,000 volumes, including many valuable MSS. Geneva has numerous literary and scientific societies, an observatory, botanic garden, lunatic and deaf-mute asylums, and other charitable institutions. The town is supplied with water from the Rhone by means of a hydraulic machine. The chief manufactures of Geneva are watches and jewellery: about 100,000 watches, chiefly gold, are made annually, employing about 3000 workmen. Its other industrial products are musical boxes, chronometers, mathematical and musical instruments, cutlery, fire-arms, &c. It also carries on an active transit trade by means of steamers with the various towns on the lake. Geneva was in the time of Cæsar one of the chief towns of the Allobroges, and it continued subject to the Romans till the beginning of the fifth century, when it was taken by the Burgundians, and made their capital. Towards the end of the fifth century it became the seat of a bishop; and in 534 came into the possession of the Franks. Charlemagne conferred upon it certain important privileges, subordinate however to the bishop, who was styled Prince of Geneva, and was an immediate feudatory of the empire. It afterwards came to form a part of the second kingdom of Burgundy; on the fall of which it became entirely subject to its bishops, between whom and the counts of Genevois in Savoy there existed incessant contests for its possession. The line of the counts of Genevois becoming extinct in the fourteenth century, their inheritance reverted to the house of Savoy, and hence are derived the claims of the dukes of Savoy over Geneva; claims, however, never completely enforced. At the Reformation the bishop was expelled, and the town, with its territory, became an independent republic. Calvin was in 1536 induced to settle here, and was soon afterwards raised to the highest rank in the state; and Geneva became the metropolis of Protestantism. The dukes of Savoy made several fruitless attempts to possess Geneva by force or by fraud; but, in 1603, by the mediation of Berne, Zurich, and Henri IV. of France, acknowledged its independence. In the eighteenth century the peace of the town was frequently disturbed by internal feuds. In 1798 it was taken by the French revolutionary forces, and became the capital of the department of Leman. In 1814 it was restored by the allied powers to its independence as a canton of the Swiss Confederation. Among the many eminent men that Geneva has produced may be mentioned Isaac Casaubon, Rousseau, Lefort the friend of Peter the Great, Necker the father of Madame de Staël, the naturalists Saussure, Bonnet, and De Luc, Decandolle, Huber, Dumont, the friend and editor of some of the works of Jeremy Bentham, and Sismondi the historian. In the beginning of the fifteenth century Geneva contained about 10,000 inhabitants, and in 1550 they had increased to about 20,000. In 1715 they numbered only 18,500, but in 1789 they had risen to 26,140. In 1830 the population was 27,000, and in 1850 31,238. The Canton of Geneva is, with the exception of Zug, the smallest of the Swiss Cantons, having an area of only 91 English square miles. It is bounded on the N. by the Canton of Vaud and the Lake of Geneva, E. and S. by Savoy, and W. by France. More than one-fourth of the canton is arable, about one-fifth is meadow land, one-tenth in wood, and one-twentieth in vineyards. The agricultural products of the canton are not equal to the wants of the inhabitants, so that considerable quantities are imported. The language of the city and canton is the French. Pop. of the canton (1850) 63,932, of whom 34,212 were Protestants and 29,764 Roman Catholics.

GENEVA, *Lake of*. See SWITZERLAND.

GENEVA, a town in Ontario county, state of New York, North America, beautifully situated at the north end of Seneca Lake, on the Auburn and Rochester railway, 50 miles E.S.E. of Rochester. It is handsomely built, and has several fine churches and a medical college. Steamboats ply daily between it and Jefferson at the head of the lake. Pop. 6000. There are several other towns and villages of this name in the United States.

GENEVA, or *Gin*, a malt spirit, distilled a second time, with the addition of juniper berries. The name *geneva* is a corruption of the French *genièvre*, a juniper berry. The method of making this kind of spirit is described under DISTILLATION, vol. viii. p. 51.

GENEVIÈVE, SAINTE, in Latin GENOVEFA, the patron saint of Paris, was born at Nanterre about the year A.D. 424. She early took the veil, and distinguished herself by her active benevolence, as much as by the austere sanctity of her personal character. Twice she saved Paris, first from Attila, who with his Huns was marching to sack the town.

Ste Geneviève offered up the most earnest prayers for the safety of the city, and, according to the old tradition, a thick cloud ascended, rendering it utterly invisible to its barbaric foes, who immediately marched off in the opposite direction. At another time, when Paris, after a long siege, was on the point of yielding under the horrors of famine, Ste Geneviève ascended the river to Troyes, whence she brought back eleven boats filled with provisions, and thus inspirited her countrymen to hold out till the enemy withdrew. Neither the date nor details of this second siege of Paris are known. Ste Geneviève died in 512 at the age of eighty-eight, and was buried in the Church of St Peter and St Paul, which, in the ninth century, came to be called by her name. This church stood till 1807, and its tower is still to be seen close to the Pantheon in the Latin Quarter of Paris.

GENÈVRE, MONT, one of the principal summits of the Cottian Alps, rising to the height of 11,788 feet. It is crossed by a carriage-way, constructed by Napoleon I., at an elevation of 6353 feet. It is one of the contested routes by which Hannibal is said to have crossed the Alps.

GENII, a race of imaginary beings who, according to Mohammedan belief, were created from fire, and hold an intermediate place between men and angels. They are supposed to eat, drink, and propagate their species, to be either good or evil, to exercise a most important influence on human affairs, and to be capable, like men, of future salvation or damnation. The orientals assert that the genii inhabited this world thousands of years before the birth of Adam, under many successive kings, who all bore the name of Solomon; that at length their depravity became such that Eblis was sent to drive them into a remote part of the earth, there to be confined; and that some of that generation still remaining, they were by Tahmorath, one of the ancient kings of Persia, forced to retreat into the famous mountain of Kaph. There are also several ranks and degrees among this kind of beings, some being called absolutely *Djin*, others *Peri* or fairies; some *Div* or giants, others *Tacwin* or fates. See MOHAMMEDANISM.

GENIL, a river of Spain, which rises in a chasm called Corral de Veleta, on the N.W. slope of the Sierra Nevada, in Andalucia, province of Granada. It flows N.W. through the town of Granada, then W.S.W. till it reaches Loja, where it turns W.N.W., passes the town of Ecija, and joins the left bank of the Guadalquivir, at Palma del Rio, 32 miles below Córdova, after a course of nearly 160 miles. It is nowhere navigable; but it furnishes much valuable water-power, and is extensively used in irrigation.

GENITIVE CASE, sometimes called the elative case, is a term applied to one of the case-forms of nouns and pronouns. One thing with another, or its predicate beginning or begotten of it, is in the genitive case. It may be called the "whereof" case: as "the fear of death," "the love of home," "the works of God," "the cup is full of wine." The natural possessive and genitive cases are clearly different, though in most languages they are both classed under the same case-form; for one thing may be the begetter of another which it may not possess, or may be the possessor of a thing which it may not have begotten. "William's field," means the field of which William is the possessor but not the begetter, while "the love of money," or "the fear of death," does not mean the love or fear which money or death possesses, as neither money nor death can possess love or fear; but this love and fear are, in the mind of man, begotten by money and by death; and in the sentence "the cup is full of wine," the wine is the begetter of the predicate "full." Since one thing with another, or its predicate beginning or begotten by it, is in the genitive case, it follows that a thing may have two genitive relations—one thing to another thing itself, and another to its predicate, as "the stab of a dagger," in which the dagger" is the begetter or generator of the stab;" "the cup is full of wine," where the "wine" is not the begetter of the "cup," but of its predicate "full." It is idle to object that to make so nice a distinction as that between the relation of the thing A to the thing B, and the relation of the thing A to the predicate of the thing B, is to make CASE needlessly perplexing; for some nations, as the Finnic, have shown such discriminations in the case-forms of their languages, and we could not understand any language in which such discriminations might be made without the distinction first existing in the mind. The "genitive" is distinguished from the "possessive" by Euren in his *Finsk Språklära*, in which he calls the latter the "genitive-possessive." From the want of this distinction in the Greek and Latin languages arises much of the perplexity in treating of the syntax of the genitive case in their grammars. A clear example of the ambiguity arising from the same case-ending answering for both relations may be seen in 2 Cor. v. 14, *ἡ ἀγάπη τοῦ Χριστοῦ συνέχει ἡμᾶς*. If *τοῦ Χριστοῦ* is possessive, it means "the love of Christ for us;" whereas if it is genitive, it means "our love for him." See Bloomfield on the passage; and Barnes's *Philological Grammar*, London, 1854.

GENIUS, in *Antiquity*, the tutelary spirit that watched over the destinies of nations, and of each individual. The idea of the genius, or *δαίμων*, is first met with in the mythology of the Greeks. Homer makes no mention of these *dæmones;* but Hesiod accounts for their origin by describing them as the souls of good men who lived in the golden age. According to him, they are 30,000 in number: their functions are to watch over the human race and carry out the will of Jove, unseen by mortal eye. This conception was taken up by the Platonists, who assigned to every man at his birth a good and an evil dæmon. According as either of these was in the ascendant, the life of the individual was influenced for good or evil. The beautiful conversations of Socrates on his good and evil genius are familiar to all who have read the works of Plato.

Like the *dæmones* of the Greeks, the *genii* of the Romans were tutelary or guardian spirits; but their functions began at a still earlier period. They were in fact (as the etymology of their name implies) the producing or life-giving powers which organized the being whom it was their duty to protect till death. On this account also the nuptial bed was called the *lectus genialis.* By every Roman citizen the genius was worshipped with especial honour, and a birthday was celebrated with offerings of the finest flowers and wine to them. Every one thought it at once a duty and a privilege to "indulge his genius" (indulgere genio), *i.e.* to enjoy to the utmost the merriment allowed on these occasions.

In the Roman mythology genii were not confined to the human race alone. Every living being, and even every place, had a guardian spirit of its own. These local genii were symbolized under the form of a serpent (the type of renovation) eating fruit placed before him. (Plutarch, *De Genio Socratis;* Hartung, *Die Relig. der Röm.;* Smith's *Dict. of Gr. and Rom. Antiq.*, &c.)

GENIUS, in its modern use, signifies generally the bent of national or individual disposition. In a more limited sense it denotes those endowments and powers of mind which one has received from nature. To define or illustrate the term, when employed in this sense, is difficult if not impossible. Fuseli described it as "that power which enlarges the circle of human knowledge, or combines the known with novelty." A better, though far from perfect, definition is that of the poet Crabbe: "I recognize genius wherever there is power to stimulate the thoughts of men and command their feelings." Better than either of these is that of Coleridge, which we extract from his *Table Talk:* "To carry on the feelings of childhood into the powers of manhood, to combine the child's sense of wonder and novelty with the appearances which every day for perhaps forty years had rendered familiar—

> ‘With sun and moon and stars throughout the year,
> And man and woman;’

this is the character and privilege of genius, and one of the marks which distinguish genius from talent.” Genius is in fact a quality so subtle and impalpable that though we are aware of its presence, and recognise it when it manifests itself, we cannot tell exactly in what it consists. It has been called by Diderot, “L’étendue de l’esprit, la force de l’imagination, et l’activité de l’âme.” That this definition is not correct is plain, because these qualities are often found separately or collectively in men to whom “the vision and the faculty divine” have been denied. In general terms, genius may be considered as that power which either creates ideas wholly new, or combines old ideas in new and unexpected forms. It is to be found in every department of thought in which the human mind has been exercised; and no work is fairly entitled to be called great which does not exhibit traces of this quality. Genius, like art, is of no country, and is not restricted to any form of thought. Galileo and Newton were as undoubtedly men of genius as Dante and Shakspeare; and if we deny the title to Tacitus we must also withhold it from Sir Walter Scott. Genius, like talent, is of various degrees; but its presence is an indispensable element in all greatness.

GENGHIS KHAN, or Zinghis Khan, a celebrated Tartar chief, in the early part of the thirteenth century, who with his barbarian hordes overran and desolated Asia. See Asia, vol. iii. p. 745, and general index.

GENLIS, Étiennette, or Stephanie Félicité Ducrest de St Aubin, Comtesse de, a voluminous French writer, was born in 1746, of a noble but impoverished family, at the château of Champcéry, near Autun. At the early age of fifteen she married the Comte de Genlis, who had been attracted to her as much by her wit and skill in music as by her beauty. A few years later the marriage of her aunt, the Comtesse de Montesson, with the Duke of Orléans, opened up to her the best society of Paris—a privilege which she turned to good account in her works. She was afterwards made governess to the duke’s children, one of whom, Louis Philippe, finally succeeded to the throne of France. The better to carry out her theory of education, she wrote several works for the use of her royal pupils, such as the *Théatre à l’usage des jeunes personnes*, *Les Annales de la Vertu*, *Les veillées du Château*, and several others. Some of these works were in a high degree useful and popular, and earned large sums of money for their author. When the French Revolution broke out, Madame de Genlis, though at first well disposed to the movement, was obliged to emigrate. Visiting successively Switzerland, Belgium, England, and Germany, and supporting herself by writing and painting, she settled in Hamburg, where she wrote her novel entitled *Les Chevaliers des Cygnes*, a story of the court of Charlemagne, ill-conceived, ill-executed, and, to judge from its results, ill-intentioned. This work gave a sort of colour to the slanderous aspersions of the royalist *émigrés*, who were exasperated at her connection with some of the extreme revolutionists. She felt her position so uncomfortable that she attempted to justify herself in a pamphlet entitled *Précis de la conduite de Madame de Genlis*. A clue to her real political opinions is only to be got from her actions, which at this time were decided enough, especially her marrying her adopted daughter, Pamela, to the unfortunate Lord Edward Fitzgerald, whose political creed was destined to bring him to an untimely and ignominious death. After the 18th Brumaire she applied to the first consul for leave to return home; and debased herself by adulations so slavish as to be only surpassed in meanness by her subsequent retractation of them. Besides the pensions and privileges which she procured from Napoleon, she realized large sums of money by hack-work for booksellers; but her utmost efforts failed to procure her admittance into the highest ranks of French literary society. She wrote a little for the *Biographie Universelle*, and out of a number of rejected articles concocted a book which she published under the title of *De l’influence des Femmes sur la littérature*. This work is distinguished by a mean spirit of detraction, envy, and spitefulness towards the leading French authoresses of that day, such as Madame de Staël, Madame Cottin, and others. About this time also she sadly befooled herself in a literary contest with Ginguené and some of the principal contributors to the *Biographie Universelle*. Indeed there was hardly a month of her literary career in which she was not engaged in one squabble or another, not seldom of a nature very discreditable to her: witness her quarrel with the publisher Roret. Of her later works, that which made the most noise in its day was her *Diners du Baron d’Holbach*, in which she set forth with a good deal of cleverness the prejudices, the intolerance, the fanaticism, and the eccentricities of the philosophers of the last century. This work, as was natural, was severely censured by the free-thinking party in France; but the author’s replies to their attacks were marked by a bitterness and malignity to which they could offer nothing parallel. Madame de Genlis attained the age of eighty-four, and died Dec. 31, 1830. Before her death she had the satisfaction of seeing her quondam pupil Louis Philippe seated on the throne of France.

To give a list of the separate works of Madame de Genlis, eighty in all, is manifestly impossible within our limits. They comprise prose and poetical compositions on a vast variety of subjects, and of every grade of merit. The swiftness with which they were written, their diffuseness, and their somewhat fugitive and transitory interest, forbid us to look in them for thought of perennial value or literary art of the highest or indeed of a high order. Posterity seems to have confirmed the verdict of Palissot, who declared that Madame de Genlis’ fame would rest solely on her *Théatre d’Éducation*. This judgment may seem rather harsh; but it is true that that work is the only one which still continues to stand the test of time, if we except perhaps some of the *Contes Moraux*, *La Duchesse de La Vallière*, and *Mademoiselle de Clermont*. Madame de Genlis owed much of her literary success to her social tact. She turned her position in the Orléans family to such good account as to make it react on her literary standing, and gain for her an eminence to which she was by no means justly entitled. Her appearance was good, and her manners in a high degree attractive and fascinating. To these qualities, and her inordinate ambition, she owed her extraordinary success in life, which she never allowed a regard for consistency or honour to interfere with. No woman of her day had a finer knack of disentangling herself from humble friends who were no longer likely to be useful, or of more delicately making herself necessary to those who stood on the higher grades of the social ladder, whose heights it was her chief ambition to climb. After she fairly reached the top, she is not known to have actively assisted or befriended any but her own nearest relations. (For a complete list of Madame de Genlis’ works see supplement to the *Biographie Universelle*, vol. lxv.)

GENOA (more accurately Genova), Duchy of, one of the administrative divisions of the kingdom of Sardinia, occupies that portion of the Ligurian Apennines which lies at the head of the Gulf of Genoa. Its extreme Lat. is 44. 2. and 44. 49. N., and its Long. 8. 20. and 10. 6. E. It is bounded on the N. by the administrative division of Alessandria, on the E. by the Duchy of Massa, on the S. by the Mediterranean, and on the W. by the administrative division of Savona. The area is 1258 square miles English, occupied by a population (1855) of 580,000.

Boundaries.

Dimensions, surface, and coast-line. The greatest length of Genoa is about 130 miles, and greatest breadth 46. The Apennines traverse this duchy from N.E. to S.W., in directions nearly parallel to the shore, from which their central ridge is seldom more than 16 miles distant. The coast line does not exceed 100 miles; but it is varied by numerous indentations, which form several good harbours and two spacious bays—Rapallo, and the beautiful Bay of Spezzia (the *Portus Lunæ* of the Romans). The surface presents a succession of mountain slopes and terraces, intersected and diversified by valleys and ravines. The greater part of it is covered by the Apennines, which curve round the Gulf, and form two slopes, from the northern of which descend the Trebbia, the Staffora, the Scrivia, the Orba, and the Bormida, all affluents of the Po; while from the southern slope descend into the Gulf of Genoa the Magra, the Vara, the Sturla, the Besagno, and the Polcevera, all streams of minor importance, besides numerous mountain torrents, which so much heighten the beauty of the landscape. **Geology.** The prevailing rocks belong to the carboniferous and magnesian limestone systems. Statuary marble and other kinds, as well as alabaster, limestone, slate, coal, and asbestos are easily obtained. **Soil, climate, and vegetable productions.** The soil is not naturally very productive, being, from its very rugged nature, for the most part rocky and unfit for agricultural purposes; but the industry and skill of the inhabitants have turned to advantage every spot capable of cultivation. The climate is in general temperate and salubrious, and the air is remarkably pure. In winter, however, the winds in the elevated ravines are bitterly cold, giving a tendency among the inhabitants to pulmonary complaints; and the influence of the sirocco is sometimes severely felt. The chief vegetable productions are citrons, lemons, oranges; light wines; chestnuts, olives, silk, cotton, hemp, figs, pomegranates, almonds, and other excellent fruits. On the mountain slopes there are fine pastures and extensive forests. **Manufactures and commerce.** The manufactures have made great progress in large towns, especially in Genoa, where, in particular tissues, it still excels the rest of the world. (See Genoa, *City of*). But the great passion of the Genoese is for the sea, whence they have in all ages been well adapted for commercial pursuits. Though they have in recent times been far surpassed by other nations, they still carry on a very important trade, both foreign and coasting. The best seamen in the Mediterranean are furnished by the Rivieras, or maritime districts, and the Sardinian navy is manned chiefly from them. Their vessels trade to the Levant, the Black Sea, the Baltic, to America, and the coasts of the Pacific. The principal articles of export are silk, paper, rice, oil, and hemp.

Roads. From the nature of the surface of this duchy there is only one main line of road traversing the length of the country. This excellent road runs along the western shore from the city of Genoa to Savona, and along the eastern shore from Genoa to Sarzana, disclosing views of the most picturesque and enchanting beauty. The transverse roads which run into this main line are the terminations of those from Lombardy and Piedmont. The only railways in the duchy are the southern portion of the Turin and Genoa Railway, opened throughout its whole extent in December 1853, and one between Voltri and Genoa, opened in 1855.

The Duchy of Genoa is divided into four provinces—Genova, Chiavari, Levante, and Novi.

People. The Genoese are a robust and handsome people; they are active, shrewd, frugal, industrious, and parsimonious. From the time of Virgil to that of Dante, the Ligurians or Genoese have been the subject of great vituperation.[1] The dialect of Italian spoken by them is one of the most difficult to strangers, and there are only a few books of poetry printed in it.

Genoa, *City of* (in Italian *Génova*, and anciently *Génua*, misnamed in the middle ages *Janua*), belongs to the kingdom of Sardinia, and is situated in a recess of the Gulf of Genoa, on the coast of the Mediterranean, at the foot of the Ligurian Apennines, in Lat. 44. 24. 20. N., and Long. 8. 52. 55. E. It is 75 miles S.E. of Turin, 73 S. of Milan, and 90 N.W. of Leghorn. **Population.** Exclusive of the garrison and seamen, the population (in 1855) was nearly 105,000 within the city walls. The garrison on an average amounts to 8000, and the merchant seamen to about 10,000. Genoa is surrounded on the land side by a double wall, of which the inner (550 yards from the sea) incloses the town, and is 6 miles in length. The outer, called Nuove Thura, erected between 1630 and 1632 A.D., encompasses several hills with the fortresses of the Sperone and the Begato, which formerly commanded the town. **Aspect.** When viewed from the sea, Genoa and its environs rise in a compact mass like a marble amphitheatre from the harbour, which is flanked by its two gigantic moles and lighthouses. The aspect is thus truly magnificent. A succession of fine buildings, more than two miles in length, stretch along the shore; the white edifices in successive terraces; numerous churches and convents; palaces and gardens on the steep sides of the hills that rear their dark, bold, bleak, and barren summits above, crowned with formidable ramparts, forts, and batteries, give the city an air of great magnificence worthy of the ancient epithet "La Superba." **Streets.** On entering the town, however, some disappointment is naturally felt by the visitor; the houses are indeed well built, but the streets are steep, narrow, crooked, and irregular, yet clean and well paved. The buildings are square and lofty, affording a pleasant shade in the scorching months of summer, and the roofs are covered with a light-coloured slate, which has a pleasing effect on viewing the city from a distance. Such streets as the Strada Balbi and Strada Nuova, which are entirely lined with marble palaces belonging to the Genoese nobles; and the Strada Nuovissima, Carlo Alberto, and Carlo Felice, which are also magnificent, must be excepted from the character of narrowness, inconvenience, and irregularity. **Squares, private palaces, and gardens.** The few squares (or piazze) open towards the principal churches and the theatre of Carlo Felice. The palaces of the Genoese patricians display not only the attractions of architecture, but of painting and sculpture: marble columns, rich friezes, balustrades, statues, arcades, galleries, fountains, all formed of the same costly materials, are here interspersed with terraced gardens, in which the myrtle, orange, and oleander bloom in rich luxuriance. The principal of these sumptuous mansions are those of Balbi, Brignole, Durazzo, Doria, Serra, Negro, Reale, Cattaldi, Rosso, Cambraso, Pallavacini, Carega, and Lercari. The marble of which these princely edifices are constructed abounds in the vicinity of Genoa, yet the modern palaces are nearly all faced with stucco. **Public buildings.** Genoa has many handsome churches: among the finest are the Cathedral L'Annunziata, built by Sauli a citizen, and the church of Carignano; about one-half of the churches, however, and among them some of the finest, were destroyed by the French during their occupation of the city at the end of the last century and beginning of the present. Besides these there are many public edifices, of which the most interesting and important are—**Palace of the doges.** the Palazzo della Signoria, the ancient residence of the doge, and the place of meeting for the public bodies. The great and little council rooms still occupy their place in this palace, though the interior was destroyed by fire; whence the fine ceilings and wainscoting have all disappeared. There are three theatres; and the hospitals vie with the palaces in magnificence. **Private houses.** The private dwellings are neat and durable, generally high, with flat roofs; and the Exchange, where the merchant princes formerly carried on their mighty trade, is now occupied by fruiterers. The Loggia de' Banchi, where the exchange is, the Ponti or quays, the Porto Franco, the lighthouse, the promenade of L'Acquasola, the Albergo de' Poveri, or great hospital, the Ospedale del Pammatone, the Banco di San Georgio, and the Strada degli Orefici (Goldsmith's Street), are also all worthy of special notice.

---

[1] Dante, *Inferno*, xxxiii., 151–154, Carlisle's edition.

Commerce. Genoa is still an important commercial city, though vastly inferior to what it was in the 14th and 15th centuries. The "superb merchant princes" of the olden time of the republic are now no more. This inferiority has been mainly brought about by the expensive wars in which the republic engaged. Still the exports amount to about two millions and a half sterling, while the imports are about four millions. Of exports, the principal articles are cheese, rice, hemp, fruits, olive oil, and hides; and of her own manufacture, paper, soap, works in alabaster and marble, jewellery, and bijoux in coral, silks and fancy goods, damasks and velvets, for the last of which Genoa has long been highly celebrated. **Manufactures.** The annual value of the silk and satin manufactures averages L.250,000; and the raw material is partly raised at home and partly imported from Sicily, Calabria, and the Levant. Gold and silver filigree manufactures of Genoa have long held a first place in the estimation of connoisseurs in such work. Other less important articles of manufacture are artificial flowers, white-lead, candied fruits, chocolate, maccaroni, and hats. **Imports.** The chief articles of import are corn from Sicily, and sometimes from Barbary; raw silk from Sicily and Calabria; naval stores and iron from the Baltic; sailcloth and linens from Germany; cottons, tin, lead, sugar, hardware, and coals from Great Britain; wood from Spain, cotton and wax from the Levant; and various articles of colonial produce from British North America and the United States. Many of these imports are again exported to Switzerland, France, and Spain. **Transit trade.** Two laws, passed in 1751 and 1815 respectively, which enabled merchants to deposit goods in the Porto-Franco without paying duty unless taken out for home consumption, have very much facilitated the transit trade, which is now very considerable. Genoese vessels trade to the Euxine, the Levant, the Baltic, and North and South America; while steamers regularly ply between Marseilles, Barcelona, Leghorn, Civita Vecchia, &c. **Harbour.** All this vast trade is much facilitated by the fine harbour of Genoa, and the liberal encouragement to trade given by the Sardinian government. The harbour is bounded at its two extremities by the Molo Vecchio and the Molo Nuovo, 595 yards apart, and above the latter stands the noble fanale or lighthouse, 385 feet above sea level. The harbour, exposed to the S.W. wind and its heavy swells, is in the form of a semicircle, whose diameter is about 2000 yards, with the Old Mole on the E. side and the New Mole on the W. The water at the New Mole is deepest, and the bottom is clay, and holds well. The Darsena, or state dock and arsenal, on the N. side of the large harbour, was established in 1276 A.D., and is used for refitting and preserving the national galleys. With it is connected the Bagne or prison for convicts. Two towers are erected on the moles, one as a lighthouse, the other as a defence of the harbour. A strong thick wall runs along the quays between the harbour and the houses, which completely conceals the former from view.

Government and laws. Genoa is a garrison town, the residence of a governor-general, and of a high court of justiciary or senate for the whole duchy. In the practice of these courts the French codes, civil and commercial, have been retained. The government of the city is vested in the great town-council of 40 members, 20 of whom are merchants and 20 nobles, a lower council, two syndics, with various subordinate officers. **Education.** For public instruction there are the university, attended by about 500 students, a royal college, a naval school, and six commercial schools, one for each district of the city, a deaf and dumb school, an academy of fine arts, public libraries, one of which contains 50,000 volumes, besides several learned societies of very old standing; yet education is not generally diffused, nor has Genoa produced many men who rank high in the republic of letters. **Eminent citizens.** Among her poets, Chiabrera the lyrist stands alone eminent. The most celebrated character of which she can boast is Andrea Doria; and Columbus who was born in the duchy, but not in the city. Oderico was a famous philologer, and Lomellini first ventured to use lightning rods. And though Genoa bears ample proofs of her liberal tastes, neither has she been distinguished as the birthplace of eminent artists. Besides all the institutions already mentioned, Genoa has 15 female asylums or *conservatorie*, as well as various convents and benevolent institutions. **Religion.** The established religion is Roman Catholic; but other creeds are tolerated, even the Jewish.

History. Few states in Europe have experienced so many political revolutions as Genoa. Old traditions would assign to it an antiquity greater than that of Rome. At the beginning of the second Punic war (218 B.C.) it is mentioned by Livy as a town in friendly relations with Rome. Shortly after this, in order to effect a diversion in favour of Hannibal, Mago, the Carthaginian general, sailed with an army on board his fleet, took Genoa by surprise and partly destroyed it; but, by order of the Roman senate, it was restored a few years after.[1] From that time Genoa continued in alliance with Rome, but was not one of her colonies. She is also mentioned by Strabo as an emporium for the sale of honey, cattle, and hides, brought from the interior by the Ligurians, who received wine and oil from the other parts of the peninsula in exchange. Involved in all the vicissitudes of the Roman empire, Genoa suffered first from the invasions of the Goths and Lombards, and afterwards from the ravages of the Saracens. Such, however, were the resources of its commerce and the advantages of its situation that it always emerged from oppression; and during the tenth century succeeded in establishing a free constitution, having rid itself of the dominion of the Frank counts imposed upon it by Charlemagne. After the fall of the Carlovingian dynasty, and during the contests about the crown of Italy, the Genoese seized the opportunity of regaining their independence, and established an aristocratic republic under elective magistrates styled consuls. From the end of the 11th century the names of the consuls were recorded. By sea the Genoese merchants had already rendered themselves formidable, having strengthened their navy in self-defence against the Saracens, from whom they had suffered severely. In alliance with the Pisans they succeeded in expelling these infidels from Capraja, Corsica, and Sardinia, between 1016 and 1021 A.D. From this time dates the domination of Genoa over Corsica and Capraja. During the great crusade under Godfrey de Bouillon, the Genoese obtained settlements along the coast of the Holy Land, especially at Acre; and in 1146 A.D. they took Minorca Island from the Moors, and the next year succeeded in storming Almeria in Granada, whence they carried off immense booty. All this time the Genoese fleet consisted of 63 galleys with 163 transports, on board of which they carried 12,000 land forces. In 1148 A.D., in company with the Catalonians, they took Tortosa, which was defended by a Moorish garrison. **Pisa as a rival power.** These conquests roused the jealousy of the rival cities Pisa and Venice, also great naval and commercial powers. Two centuries of almost uninterrupted war between Genoa and Pisa succeeded, terminating in the complete defeat of the latter in a naval engagement near the rocks of Meloria in sight of their own coast. In this decisive and desperate battle, 3000 Pisans were killed and 13,000 taken prisoners to Genoa, where they mostly died in chains. The Pisans never recovered from this blow; and nine years afterwards (1290 A.D.) the Genoese, under Conrad Doria, destroyed Porto Pisano, and filled up the mouth of the harbour.

Venice as a rival power.

Soon after the conquest of Constantinople by the Franks in 1244 A.D., the rivalry between Venice and Genoa began to manifest itself. Michael Palæologus, having been considerably assisted by the Genoese in recovering his capital, granted them the important suburbs of Pera and Galata, and the port of Smyrna, with full jurisdiction over them all; and thus virtually granted them the command of the commerce of the Levant. This brought them into collision with the best interests of the Venetians, who disputed with them the supremacy of these seas. After several naval engagements, however, the two hostile republics concluded a truce in 1271 A.D. But after the decisive conquest of the Pisans the Genoese felt themselves more free to renew the contest with their other great rivals the Venetians; and putting to sea a large fleet and sailing up the Adriatic, they defeated the Venetians near the island of Curzola, destroying 84 galleys, and making 7000 prisoners, including the Venetian Admiral Dandolo. In 1299 a peace was concluded between these fierce rivals, by which the Venetians were entirely excluded from the trade of the Euxine, where the Genoese had studded the coast with a chain of forts, factories, and colonies, by means of which they pushed their trade far into the interior of Asia. Their commerce had now reached its greatest height. The markets of Constantinople were now wholly supplied by the enterprising and warlike merchants of Genoa; and under their auspices Kaffa, now and anciently Theodosia, became one of the finest commercial towns in Europe. At this time the Genoese not only commanded the Euxine, but had a communication with the Caspian, by which they received the costly merchandise of India. When Mohammed II. conquered Constantinople (1453 A.D.) he seized the Genoese colonies in the Euxine, which fell an easy prey to him while internal dissensions agitated the parent city at home. But long before this, in 1346, the Genoese had again come into collision with the Venetians, whom they defeated in sight of Constantinople, but were themselves afterwards totally routed on the coast of Sardinia. After this disheartening defeat the Genoese submitted to Visconti Duke of Milan, and from 1381 A.D. Venice and Genoa remained at peace. The rule of the podestà had succeeded that of the consuls about 1190 A.D. With some interruptions this lasted till 1270 A.D., when Spinola and Dona, two eminent citizens, usurped the supreme power, calling themselves "Captains of Liberty," and they retained it till 1291 A.D. The lower classes were reconciled to their rule by their appointing a magistrate called Abbate del Popolo, who vindicated the rights of the people against the nobles. Next were appointed "foreign captains" chosen from among the natives of places at least 100 miles distant from Genoa. Next was instituted a council, consisting first of 12, then of 24 members, of equal numbers of nobles and plebeians. Endless feuds arose within the city between these classes, who rendered the city with its territory almost a desert, so that in 1339 A.D. the citizens, disgusted and weary of discord, appointed a magistrate called *doge*, elected for life, excluding by law all the nobles of every faction from ever filling the office. This mode of government, with frequent contests between the chief citizen families, lasted two centuries. Taking advantage of these feuds, the Visconti of Milan and the kings of France at different times got possession of Genoa. But at length Andrea Doria delivered his country from the French, and changed the form of government by establishing biennial doges, with councils to assist and control them. This form of government lasted from 1528 till the invasion of Italy by Napoleon, when the democratic party overpowered the aristocracy after a dreadful contest, and received the protection of a French garrison. In 1799, the French under Massena were besieged within Genoa by the English and the Austrians, to whom they capitulated; but the city was again given up to the French after the battle of Marengo. A new form of government was then imposed upon Genoa by Napoleon as consul, leaving it only a nominal independence under the name of republic. When he became emperor, however, he compelled the doge and senate to submit to the annexation of Genoa to France. In 1814 Genoa surrendered to the English; and in 1815, by a decision of the Congress of Vienna, it was united to the Sardinian monarchy, and since that time the spirit of commercial enterprise among her citizens has greatly revived, and a large amount of prosperity has been regained by the city. In 1850 the city was seized by insurgents, who drove out the garrison and proclaimed a republic, April 1850; but before the end of the same month these insurgents surrendered to General Marmora.

Foglietta and Caffaro, the old chroniclers; *Istoria dei Liguri e dei Genovesi*, by Serra; Dr William Smith's *Dictionary of Greek and Roman Geography*; *Storia d'Italia*, by Botta; *Annali di Genova*, Giustiniano, in folio, Genoa, 1537; *La Chronique de Gennes*, 8vo, Paris, 1507; *Histoire du Consulat et de l'Empire*, by Thiers; Murray's *Hand-Book of Northern Italy*, &c.

Genoa, *Gulf of*, anciently called *Sinus Ligusticus*, is a large bay in the Mediterranean, lying N. of the island of Corsica, and washing the southern shores of the Sardinian provinces in Italy. No precise points can be named as marking its limits, for it opens widely and imperceptibly from the main body of the Mediterranean. It may, however, be said to comprise the whole space north of the parallel of 43. 40. N., though it is more usual to confine the appellation to that portion of this large bight which lies to the north of the parallel of San Remo, 43. 48. 44. N. Lat., and 7. 50. 0. E. Long. Thus defined, its entrance is about 140 miles in width, and its extreme breadth 54 miles. Its outline embraces the beautiful minor bays of Spezzia and Rapallo, as well as the capes of La Mele, Chiapa, and Venere.

Genoa, a township in the Cayuga county, State of New York, United States, situated on Big Salmon Creek, 162 miles W. of Albany. The post-village of the same name is pleasantly situated on the creek in this township, and contains two churches, an academy, two mills, and an iron foundry. The Auburn and Ithaca Railway passes through the village. Pop. (1850) 2503.

GENOVESI, Anthony, an eminent Italian writer, born November 1712, at Castiglione, near Salerno. After receiving a preliminary education in his native village, at his father's desire he commenced the study of scholastic theology, with a view to the ecclesiastical profession. He soon distinguished himself as a proficient in dialectics; but in consequence of his having formed an attachment to a young woman, he was removed by his father to another village, where he found a priest who diverted his attention to different objects. Having been afterwards excommunicated by the archbishop of Conza for acting a part in a comedy, he returned to Castiglione; and finding his mistress married, he re-assumed the cassock, and took priest's orders at Salerno in 1736. Here he soon distinguished himself so much by his talents, that the archbishop of this town promoted him to the chair of eloquence. At this period Genovesi was a mere school theologian; but he now began to perceive that there were sources of knowledge beyond the scholastic sphere, more extensive, more interesting, and more real than those to which he had hitherto applied. Genovesi entered into this new intellectual world by the perusal of some romances; from these he proceeded to the study of history; and finally applied himself to the study of modern philosophy, particularly the works of Leibnitz and Locke. He then went to the capital, where he endeavoured to maintain himself as an advocate; but becoming disgusted with the details of practice, he soon abandoned it, and devoted himself to study. He improved his knowledge of the Greek, and of several of the modern languages, attended all the most celebrated professors of the university of Naples, and soon perceived the imperfections of the system of public instruction. He accordingly resolved to effect its reform, with a view to the amelioration of the condition of his countrymen. Although there existed at Naples a university celebrated for the learning of several of its professors, the pupils had long been accustomed to carry on their studies in private schools. Genovesi having conceived the design of opening one of these seminaries, he procured the appointment of extraordinary professor of metaphysics in the university, in order that he might appear before the public in a known character. He had formed peculiar methods of his own in all the faculties which constitute the philosophical course; and his first essays induced him to publish his *Elements of Metaphysics*, of which the first volume appeared in 1743, and afterwards, in 1745, his *System of Logic.* In these two works he made ample use of the doctrines of Bacon, Descartes, Leibnitz, and Locke; and having substituted philosophical doubt for implicit belief, the observation of nature for the speculations of the schools, and reason for authority, he was denounced as an infidel, or at least as an irreligious person, by those who still adhered to the scholastic methods. He was supported, however, by Galiani, archbishop of Tarentum, grand almoner of the king, and grand master of the university; yet notwithstanding this protection he experienced some trouble and difficulty in obtaining the professorship of moral philosophy; and was disappointed in an attempt to procure the chair of theology.

The unjust and obstinate hostility he suffered on account of his theological works diverted him for a time from this path of inquiry, and brought him back to that of philosophy. He published a continuation of his *Elements of Metaphysics;* but with every new volume he continued to experience the censures and opposition of the partizans of the scholastic routine. Among these were the Cardinal Spinelli, archbishop of Naples, and an Abbé Magli, whom Genovesi covered with ridicule in his work entitled *Lettere à un Amico Provinciale.* In spite of these continual jarrings, Genovesi obtained the approbation and esteem of Pope Benedict XIV., of several cardinals, and of most of the learned men who at that period flourished in Italy. Of this number was Intieri, a Florentine, alike distinguished for his philanthropical qualities and the extent and solidity of his acquirements. It is to him that Italy is indebted for her first chair of political economy, which he founded at his own expense in the university of Naples, under three conditions, namely, that the lectures should be in Italian, that Genovesi should be the first professor, and that, after his death, no ecclesiastic should succeed him.

Genovesi opened his first course of lectures on the 5th of November 1754, with great success. The novelty and the interest of the subject, the eloquent style and agreeable manner of the professor, attracted a crowd of auditors, and made a deep and lively impression. Nothing, indeed, was talked of but agriculture and commerce. Genovesi afterwards published his *Lectures on Commerce*, and Carey's *Account of the Trade of England* translated into Italian by his brother, with notes by himself. The great success of these lectures, which were delivered in Italian, induced Genovesi to draw up a complete code of philosophy in that language, so as to render the work accessible to those classes to whom the Latin tongue was not familiar. He had published in Italian his *Meditazioni Filosofiche*, on religion and morals; and his *Lettere Accademiche*, on the utility of the arts and sciences—a treatise written in opposition to the well-known work of Rousseau on that subject. Following out his plan, he began to recast all his Latin works, and to improve their form, so as to render them more generally interesting. The first of these was his treatise on *Logic*, which went through several editions. Then his *Metaphysics* appeared, in three parts, viz., on cosmology, theology, and anthropology. In 1767 he published part of a work on the *Science of the Rights and Duties of Man;* but this was never completed. In all his writings the style is somewhat affected; at the sametime they present us with a good exposition of the ideas and systems of the most celebrated philosophers.

After the suppression of the order of the Jesuits, when it became a question with the government whether they ought to be reinstated in their superintendence of public instruction, Genovesi was consulted, and his advice was to replace the scholastic chairs by schools of mathematics, physics, and history; and he proposed one chair for the illustration of Cicero *De Officiis.*

From the commencement of 1763 Genovesi had felt the symptoms of a dangerous malady; but he continued to teach and to write to the last day of his life; and he had the satisfaction of witnessing the great success of his labours. Since the days of Telesius and Campanella no school had attained more credit and celebrity at Naples than that of Genovesi. Pupils of all ranks flocked to his lectures; and those who heard him generally adopted his ideas. He handled the most abstruse subjects in the most agreeable manner, and thus secured a great command over the attention as well as over the judgment of his pupils. Indeed all that Italy has since produced in philosophical and economical science may be said to have originated in the school which he founded. Genovesi died of a dropsical disorder, September 22, 1769, aged fifty-seven.

The following list of his works is taken from Fabroni, *Vitæ Italorum doctrina excellentium*:—1. Disciplinarum metaphysicarum Elementa Mathematicum in morem adornata, 1744–1751, 4 vols. 8vo; 2. Elementorum Artis logico-criticæ libri quinque, Neapolis, 1745; 3. Discorso sopra alcuni trattati d'Agricoltura, ibid. 1753; 4. Lettere Accademiche, ibid. 1764; 5. Storia del Commercio della Gran Brettagna, &c., 1757; 6. Delle Lezioni di Commercio; 7. Discorso sopra l'Agricoltura, with a translation of Tull's Husbandry; 8. Discorso sul volgarizzamento del Saggio Francese sull' Economia de' grani, Naples, 1765; 9. Meditazioni Filosofiche sulla Religione e sulla Morale, ibid. 1766; 10. Della Filosofia del giusto e dell' onesto, 1766–1776, 3 vols.; 11. Universæ Christianæ Theologiæ elementa dogmatica, historica, critica, a posthumous work, Venice, 1771, 2 vols. 4to. (J. C.)

GENS, in *Roman Antiquity*, a clan, embracing several families, whose bond of alliance was a common name and certain religious rites performed in common. The *Gens Cornelia*, for instance, comprised the families of the Lentuli, Cethegi, Scipiones, and many others. Persons of the same gens were called *Gentiles*, while those of the same family were designated Agnati. At first patricians only were considered to have a gens; but after the plebeians obtained the right of intermarriage with the patricians, and access to the honours of the state, they likewise received the rights of gentes. Hence there were both patrician and plebeian gentes; and sometimes in the same gens there were both patrician and plebeian families. (See Niebuhr's *Röm. Gesch.*, vol. i., p. 339; Adam's *Roman Antiquities;* Freund's *Lexicon*, &c.)

GENSERIC, king of the Vandals, was the most formidable of the Gothic invaders of the Roman empire. In 429 A.D. he became king of the Vandal settlers in Spain, and in that same year crossed over into Africa, where he subjugated the Roman provinces of the north, and committed the most frightful devastations. His next exploit was to fit out a fleet, in which he sailed to Ostia, whence he marched to Rome, which he stormed, and gave up to his soldiers to be pillaged during fourteen days (A.D. 455). Two attempts were made by the Romans to avenge themselves on the barbarians; the first by Majorian, emperor of the west, in 457; the second by Leo, emperor of the east, in 468. Both of these attempts, however, signally failed. Genseric spent the remainder of his life in consolidating his conquests, and died at a great age in 477. He was cruel to bloodthirstiness, cunning, unscrupulous, and grasping; but he possessed great military talents, and his manner of life was austere. Though the effect of his victories was neutralized by the subsequent successes of Belisarius, his name long remained the glory of the Vandal tribes. (Comp. Procopius' *De Bell. Vandal.*; Gibbon's *Decline and Fall*, chap. 33-36.)

GENTIAN, a genus of plants belonging to the nat. ord. *Gentianaceæ*. It includes about a hundred species, many of them remarkable for the beauty of their flowers, which are usually of different shades of blue, but sometimes red, purple, yellow, or rose-coloured. See BOTANY, vol. v., p. 200. The officinal gentian is the dried root of *Gentiana lutea*, a native of the Alps, which has a stem about three feet high, broad ovate leaves, and numerous yellow flowers. It has an intensely bitter taste, and is in general use as a tonic in diseases of debility. Its febrifuge virtues have been celebrated from antiquity, and it was a much-valued remedy in intermittents before the introduction of cinchona, for which it is still sometimes substituted. All the species contain the bitter principle in abundance.

GENTILE (Lat. *Gentilis*, from *gens*, a nation) is used in Scripture to denote a pagan, or worshipper of false gods. The Hebrews included all the inhabitants of the earth except the Israelites under the common name of גוֹיִם (*goïm*), *i.e.* 'nations;' in the Greek rendered τὰ ἔθνη, and in the Latin by *gentes*. By degrees this appellation came to be used by the Hebrews in a reproachful sense, on account of the idolatry of the surrounding nations. It was afterwards used by the Jewish converts to the gospel as a common designation for such as were neither Jews nor Christians. St Paul is styled emphatically the apostle of the Gentiles, because the sphere of his labours lay chiefly among the foreign pagans.

In the Roman law and history the word gentile is used as equivalent to *barbarian*, which was applied to all who were not Romans.

GENTILESCHI, HORATIO, an Italian painter, born at Pisa in 1563. After having made himself famous at Florence, Rome, Genoa, and in other parts of Italy, he removed to Savoy, from thence to France; and at last, on the invitation of Charles I., came over to England. He was appointed lodgings at court, with a considerable salary, and employed to decorate the palace at Greenwich and other public places. His best performances in England were the ceilings of Greenwich and York House. He also executed a Madonna, a Magdalen, and Lot with his two daughters, for the king. His attempts in portrait were feeble, his talent lying altogether in the historical style, with figures the size of life. After twelve years' residence in England, he died at the age of eighty-four, and was buried in the Queen's Chapel at Somerset House.

GENTILIS, ALBERICUS, a laborious jurisconsult of the sixteenth century, with more erudition than taste or judgment, was born in 1551 at Castello-di-San-Genesio, in the March of Ancona, and studied at Perugia, where he took the degree of doctor in civil law at the age of twenty-one. Soon afterwards he was appointed a judge at Ascoli; but not having it in his power to profess there in security the Protestant religion, of which he was an ardent follower, he went to seek an asylum in Carniola, and ultimately in England. During his stay in London, where he continued for several years, he lived entirely on the bounty of some generous friends of the sciences. At length the Earl of Leicester procured him, in 1587, the chair of law in the university of Oxford, which, with other lucrative appointments, he held till his death in 1611. The labours of Albericus Gentilis in jurisprudence give him but small claims to our esteem. His views are often erroneous, and the sound doctrines which may be found in his works are buried in a mass of citations without end, from the philosophers, fathers, poets, historians, and jurisconsults. But his treatises on the law of nations have rendered his name worthy of a place in the history of jurisprudence. His book *De Jure Belli* contains excellent views on a science which Aristotle and Cicero have not even touched on; and if the author has not sufficiently fathomed his subject, he has at least the merit of having furnished abundant materials to Grotius, who knew better how to use them.

An exact list of the works of Gentilis may be found in the *Mémoires* of Nicéron (tomes xv. and xx.); but it may be sufficient here to indicate the following: *Liber Conditionum*, Wittemberg, 1580, 8vo; *De Juris Interpretibus Dialogi Sex*, London, 4to; *De injustitia bellica Romanorum actio*, Oxford, 1590, 8vo; *De Jure Belli libri tres*, Hanau, 1598, 8vo; *Disputationes duæ, prima de actoribus et spectatoribus fabularum non notandis, secunda de abusu mendacii*, Hanau, 1599, 8vo; *Ad Joannem Rainoldum de Ludis Scenicis epistolæ duæ*, Middelburg, 1699, 4to; *Disputationes tres, prima de libris Juris Canonici, secunda de libris Juris Civilis, tertia de Latinitate veteris Bibliorum versionis male accusata*, Hanau, 1604 and 1605, 8vo; *De Linguarum mixtura disputatio parergica*, Hanau, 1604, 8vo. (J. B—E.)

GENTLEMAN (from the root of *gens*, a family), a designation which in its most extended sense comprehends every man (whether titled or untitled) whose condition is above that of a yeoman. In a more limited sense it denotes one without a title who bears a coat of arms, or whose ancestors have been freemen. By courtesy, however, this title is generally accorded to all persons above the rank of common tradesmen when their manners and deportment are indicative of a certain amount of refinement and intelligence. But in its best and highest sense, this word is used to denote one who not only does what is right and just, but whose conduct is regulated by a true principle of honour, which springs from that self-respect and intellectual refinement which manifest themselves in unconstrained yet delicate manners.

The word is a synonym of the French *gentilhomme*, with the substitution of the Saxon *man* for the corresponding term of the Norman French. This again is from the Latin *gentilis homo*, which was used by the Romans to signify one who belonged to a *gens* or family. The meaning of this term is explained by Cicero (*Top.* vi.) as follows:—*Gentiles sunt, qui inter se eodem sunt nomine, ab ingenuis oriundi, quorum majorum nemo servitutem servivit, qui capite non sunt diminuti.* The word gentleman, as connected with *gentilis*, has its equivalent in most of the languages of western Europe that are derived from the Latin. Thus in Italian it is *gentiluómo*; and the Spanish has *gentilhómbre*, though the equivalent term in that language is rather *hidálgo*, or *hijo d'álgo*, *i.e.* the son of somebody, or a person of note. Some have maintained that the word is derived from *gentilis* in the sense of *pagan*; and that the ancient Franks when they conquered Gaul, which had been converted to Christianity, were called by the natives *gentiles* as being yet heathens. Others state, that in the decline of the Roman empire, as recorded by Ammianus Marcellinus, there were two companies of soldiers distinguished for their valour, the *gentiles* and the *scutarii*,—and that hence we derive the terms *gentleman* and *esquire*: to which opinion Pasquier inclines, especially as it was to these brave soldiers that the principal portions of land were assigned.

GENTLEMAN-USHER *to the Black Rod*, an officer belonging to the Garter, and chief usher to the sovereign. It is his duty to attend the House of Peers during the sitting of parliament, to regulate the ceremonial forms of the house, and to carry messages to the Commons. He has no fixed salary, but derives his emoluments from fees regulated by the house. He has also the appointment of the doorkeepers, messengers, and other servants of the house.

GENTLEMEN-PENSIONERS, a band of forty gentlemen, instituted by Henry VIII. in 1509, to form a guard to the royal person to and from the chapel-royal, and on other occasions of solemnity. In 1834 this corps resumed, by royal command, its ancient title of "*The Honourable Corps of Gentlemen-at-Arms*;" and it was further ordered, that the appointments should be made exclusively by the sovereign, from lists kept by the commander-in-chief, and on his recommendation, and that none should be eligible but officers of the army or marines, who should also be allowed to enjoy their half-pay along with their salaries. These appointments are placed on the same footing with respect to purchase, and vacancies by death, as commissions in the army. The corps consists of the captain with a salary of L.1000 a-year, the lieutenant with L.500, the standard-bearer with L.310, the clerk of the cheque with L.120, and of forty gentlemen who are entitled esquires and receive L.70 each per annum. They form a body-guard to the sovereign; but their duty is now chiefly confined to an attendance at drawing-rooms, levees, coronations, and other state ceremonies. (*Official Handbook*, Lond., 1855.)

GENTOOS. See Hindustan.

GENUS, in a general sense, is an assemblage of objects, whether persons, animals, plants, inanimate or abstract things, related by some common resemblance in natural qualities. In logic it signifies that which has several species under it; or it may be defined as a universal which is predicable of several things of different species.

In natural history it is used to denote an assemblage of species which possess certain common characters by which they are distinguished from all others. It is subordinate to *class* and *order*, and, in some arrangements, to *tribe* and *family*. Sometimes a single species, possessing certain peculiar characters distinct from all other species, constitutes a genus.

Genus, in *Music*, signified a particular arrangement of the sounds forming the ancient Greek scales, diatonic, or chromatic, or enharmonic. (See the Musical Histories of Burney, Martini, and Forkel.) (G. F. G.)

GEOCENTRIC, having the earth for its centre, or the same centre as the earth; a term applied in astronomy to the place of a planet as seen from the centre of the earth, in opposition to its *heliocentric* place, or that point in the ecliptic in which the planet would appear if viewed from the centre of the sun.

GEODESY (γῆ, and δαίω I divide), that part of practical geometry which relates especially to the measurement and division of surfaces. In its more extended signification geodesy embraces all the trigonometrical and astronomical operations necessary for the construction of maps, for measuring the length of a terrestrial degree, &c.; and includes, in short, all those operations which relate to the measurement of the earth's surface. See Figure of the Earth, Geography, and Trigonometrical Survey.

GEOFFREY of Monmouth, an ancient English chronicler, was born about the beginning of the twelfth century, in the town from which he took his name. A room in the Benedictine monastery of Monmouth is still pointed out as the place where he studied. He entered the church, became archdeacon of Monmouth in 1152, was promoted in 1152 to the see of St Asaph, and is supposed to have died in 1154. Geoffrey's *Chronicon, sive Historia Britonum* professes to be, and probably is, a translation from the Welsh. The Welsh original fell into his hands through Walter, archdeacon of Oxford (a different person from Walter Mapes, who has been very often confounded with him), who got possession of it in the course of a tour through Armorica or Brittany. Geoffrey, who undertook to translate it, executed his task with great fidelity. The work itself is a history in nine books of the Welsh from the time of their leader Brut, the great-grandson of Æneas! to the death, in 688, of Cadwallader, whom the Saxon chroniclers name Ceadwalla, and describe as king of Wessex. This work does probably not possess much historical value, but it is important as containing the legends and traditions of the Kymri in a better form than they are to be found elsewhere. The outline of Geoffrey's history is all to be found in Nennius, who preceded him by at least three centuries. But the splendid tale of Arthur and his knights had fallen into complete oblivion, till revived by the monk of Gloucester into fresh life and universal and enduring popularity. For this service alone does Geoffrey deserve to be gratefully remembered by us, and to be forgiven the many fabulous and trifling stories which he has grafted on historical outline in such numbers as to make some critics, Buchanan among the rest, regard his entire work as a fiction. The style of the *Chronicon* is lively and agreeable, and the Latinity, though far from perfect, is greatly superior to that of most contemporary chroniclers.

There are several editions of Geoffrey's history. The oldest is that printed by Ascensius at Paris in 1508, and again in 1517. It is also contained in Commeline's Collection, Heidelberg, 1587. It was translated into English in 1718 by Aaron Thompson of Queen's College, Oxford. (Tanner, *Bibl. Britan. Hib.*; Chalmers, *Biog. Dict.*; Craik, *History of Learning and Literature*, &c. &c.)

GEOFFROY SAINT-HILAIRE, Étienne, one of the most eminent naturalists of modern times, was a native of Étampes (Seine-et-Oise), where he was born, April 15, 1772. By his genius, energy, and skilful investigations, during a long career as professor of zoology to the faculty of sciences of the Académie de Paris, and at the Jardin du Roi, he contributed more than any other naturalist, except his great contemporary and friend Cuvier, to the progress of the science and philosophy of natural history. Destined by his parents for the clerical profession, he was entered at the college of Navarre, in Paris, in order to study philosophy and the other branches reckoned necessary as preparatory to a theological course. At this time Brisson was professor of experimental philosophy in that college, and gained immense influence over the mind of the young student, who felt instilled into him an enthusiastic love of nature in all its wonderful variety. This inclination greatly strengthened the sympathy between Geoffroy and his teacher. Having completed the term of his literary studies, he left the college of Navarre, and obtained his father's permission to enter the college of Cardinal Lemoine. Notwithstanding the high and honourable position in the church held out to him through powerful patronage, Geoffroy wished to pursue studies more in harmony with his peculiar tastes and sympathies; and while hesitating about which department of natural science he should devote his attention to, he was much assisted in coming to a decision by making the acquaintance of the celebrated Haüy, then one of the professors in the Cardinal's college. Haüy became his warm, steady, and attached friend, and by his example and counsels greatly assisted him in developing the tastes which the lectures of Brisson had aroused. The consequence was, that from this moment Geoffroy enthusiastically devoted himself solely to the study of the natural sciences. In pursuance of his determination, he first, in company with Haüy, took the mineralogical course at the Collège de France. Daubenton, who filled this chair, was not slow to perceive the decided bent and talent of his pupil. At the conclusion of his lectures, being in the habit of entering into conversation with his pupils, for the purpose of affording explanations to his auditors on points which might to them seem obscure, Daubenton was struck with the depth of the remarks and questions elicited from the young Geoffroy on such occasions; and even then he predicted the distinguished rank which his pupil would one day occupy in the scientific world.

The labours of Geoffroy and his friend Haüy, however, were interrupted by the revolution of 1789. During the massacre of September 1792, Geoffroy, at the risk of his own life, was the means of saving several priests; and among them Haüy, who had been imprisoned for recusancy. This act of devotion so endeared him to his teachers, especially to Daubenton, that through his instrumentality he was appointed, in 1793, to an office in the Jardin des Plantes, where he founded the vast zoological collections which form one of the true glories of Paris. By the law of June 10, 1793, the Jardin du Roi was constituted a school for advanced instruction in all branches of natural history, conducted by twelve eminent professors, each distinguished in his own branch. Scarcely entered on his twenty-fourth year, and very recently having applied himself to the study of mineralogy, Geoffroy was judicially selected by Daubenton for the chair of zoology (section, *vertebrate animals*), an appointment which he more recently shared with Lacépède.

Having thus become the colleague of Daubenton, Fourcroy, Jussieu, Lacépède, Lamarck, Vauquelin, and Latreille, Geoffroy devoted himself with enthusiastic energy to the study of zoology exclusively. For the purpose of extending the sphere of this science, he earnestly and cordially encouraged the efforts of all those who attempted to assist in its progress; and to this zeal it is that Europe owes one of the men who have rendered her pre-eminently illustrious in the science of natural history—the celebrated Cuvier. During the years 1795 and 1796, Geoffroy and Cuvier resided together, sharing with each other everything that could strengthen the already strong natural sympathy of their natures. Soon after this Cuvier was appointed joint professor of comparative anatomy with his bosom friend—an honour which justified the presage that called him to Paris, " pour remplir le rôle d'un nouveau Linné."

In 1798, Geoffroy was selected as one of the great scientific expedition to Egypt; and in the execution of his functions he displayed great firmness in preserving to his beloved Paris immense treasures of precious materials collected and prepared with infinite pains during that memorable expedition in behalf of science and art. After the capitulation of Alexandria, these treasures were only saved by Geoffroy threatening to destroy them when the English general wished to retain them: " We ourselves shall burn our treasures," said he, " and history will not fail to record that you have burned another library in Alexandria." From Egypt Geoffroy transferred to Paris a curious and most interesting collection of ancient animals; and he inserted in the great work upon Egypt learned observations on the natural history, as well as on the civil history and theogony of that interesting and inexhaustible country. On his return to France he continued his course of lectures on natural history. He was one of the first men of science and literature on whom Napoleon bestowed the cross of honour, and in 1807 he became a member of the institute, and soon afterwards associate of the Académie de Médecine, as well as of most of the scientific institutions of Europe; then professor of zoology to the faculty of sciences (1809), still holding at the museum the chair created in 1793.

In 1810 a mission into Portugal for the re-organization of public instruction held out to his courage, his love of science, and his benevolence, a new occasion of manifesting themselves in all their comprehensiveness. Once more, we are told, did the English wish to despoil him of his rich choice collections; but these were saved to him by the intervention of the conservators of Ajuda, who attested to the English commissaries that these collections had been granted to the French naturalist in exchange for minerals brought from Paris, and that the classification of the Cabinet of Ajuda was the fruit of this philosopher's labour. This declaration, with the sacrifice which Geoffroy made of several cases containing his own property abandoned to the exigencies of the people, allowed him to enrich the museum of Paris with a complete collection of the productions of Brazil.

The works of Geoffroy Saint-Hilaire do not constitute a regular system; they are composed of detached Mémoirs in which are contained some new and bold ideas of which no one disputes the originality and depth, though in their application they often lose much of their justness and value. The limits of a brief notice permit only a very brief analysis of the systems he developed in order to arrive at the solution of philosophical and physiological questions of the highest interest.

In psychology, Geoffrey Saint-Hilaire enunciated some negative ideas only. The soul, which he calls a psychological element, is not an entity any more than a metaphysical abstraction, according to his theory. This being, composed at once of a spiritual and a material principle (*spiritus corporeus*) cannot represent the intelligent, since no part of matter can belong to intellectual functions. In this manner he tells us what the soul is not; but what it is he nowhere informs us, nor does he even attempt a solution of the question so often earnestly asked—What is the soul?

In his physiological views, however, Geoffroy is explicit and positive. In formal and direct opposition to the philosophy of final causes, he has exerted all his efforts to demonstrate that it was not with any view to their results that the organs of animated beings have been created. This miserable and arid system, which would prohibit us from contemplating with gratitude the boundless intelligence of the Author of nature, has been too successfully refuted ever to be mooted again with the faintest hope of success.

It was imputed to Geoffroy that his doctrine necessarily led to atheism; because if all the existing species of organic beings could have descended from one antediluvian species, the intervention of creative power was useless; and that if both unorganized matter and organic matter are eternal, the intervention of a creator was impossible. This imputation Geoffroy indignantly scouted and disavowed as necessarily arising out of his doctrines. In his *Notions de Philosophie Naturelle* (1838), he complains that he has been misunderstood; that his doctrine does not suppose the existence of such an antediluvian species; and that by the term " Typal Unity," he means unity of organic composition, which means quite a different thing.

The most important of the published works of Geoffroy Saint-Hilaire are:—*Philosophie Anatomique*, 1823; *Système dentaire des Mammifères et des oiseaux*, 1824; *Histoire Naturelle des Mammifères*, in concert with Cuvier, 1819, second edition, 1828, *et seq.*, 4 vols. 4to; *Cours d'Histoire Naturelle des Mammifères*, 1828; *Des Considérations sur les Singes qui se rapprochent le plus de l'Espèce Humaine*, 1836; *Notions de Philosophie Naturelle*, and some biographical fragments, 1838. Besides all these, there are numerous contributions by him in several literary journals; and he was one of the collaborateurs of the *Dictionnaire des Sciences Naturelles* and of the *Dictionnaire Classique d'Histoire Naturelle*, in which he was chiefly aided by his son, Isidore Geoffroy Saint-Hilaire, M.D., and Member of the *Academie des Sciences.*

Geoffroy Saint-Hilaire died June 19, 1844; and his *Life, Works, and Theories*, have since been published by his son. The title is: *Vie, Travaux, et Doctrine Scientifique D'Étienne Geoffroy Saint-Hilaire; par son fils, M. Isidore Geoffroy Saint-Hilaire*, Paris, 1847. (A. F. F.)

GEOGRAPHY.

INTRODUCTION.

Introduction.

The term Geography, derived from two Greek words, γεα, *the earth*, and γραφω, *I write*, signifies *a description of the earth*. The description to which this title is applied may be more or less general; either embracing such truths only as belong to the earth considered as one whole, or extending to particulars which belong to and distinguish the several countries spread over its surface. In whichsoever of these two aspects the subject be regarded, a vast field opens to the view of the observer. In order to give a full and accurate description of the earth, it would be requisite to consider it in reference to its motion, figure, and magnitude; in reference to its relation to the other bodies of the universe, and more especially to the planetary system of which it forms a part; in reference to its surface, as diversified by land and sea, mountains and valleys, lakes and rivers; in reference to the materials which compose its crust, and to its internal structure; in reference to the constitution of the atmosphere with which it is surrounded, and the effects arising from the variations in atmospherical pressure, temperature, and humidity. Nor would it be enough to consider the earth only as a mass of inert and unorganized matter; it would be necessary to regard it in its relations to vegetable and animal life; and to trace the phenomena which these, in their endless variety, present in its various divisions and provinces. It would still further be necessary to view it as the abode of man himself, and as modified by his existence; divided into states and kingdoms; adorned with cities, and all the noble monuments of civilized life.

Such is an outline of the picture which geography, in the most unlimited meaning of the term, should exhibit of the globe. To fill up this picture in all its parts, it would evidently be necessary to call in the aid of the whole circle of the sciences. But the description is usually of a less extended character, being confined chiefly to the more obvious and striking features of the various regions and countries of the earth.

In the wide range which the subject presents, several divisions and subdivisions are suggested by the different views in which the earth may be considered. The three following divisions are the most important:

1. *Mathematical Geography*, which illustrates, on astronomical principles, the figure, magnitude, and motion of the earth; teaches how to determine the positions of places on its surface; explains the construction of globes, with their application to the solution of problems; and shows how the whole or any portion of the earth's surface may, on the principles of projection, be delineated on a map or chart.

2. *Physical Geography*, which treats of the mutual relations of the diversified objects found on the surface of the earth, including the atmosphere by which it is surrounded; and explains the causes, whether of a chemical or mechanical description, that produce the modifications and changes which are continually taking place in them.

3. *Political* or *Historical Geography*, which describes the earth as divided into countries, occupied by various nations, and improved by human art and industry. It traces the circumstances and character of the different races and tribes of mankind, explaining their social institutions, and ascertaining the place which each occupies in the scale of civilization.

From this general arrangement of the subject, it is evident that geography depends for its rank as a science on its intimate connection with various branches of knowledge, which, taking their rise from investigations instituted in reference to the nature and mutual relations of the objects on the earth, or connected with it, furnish those accurate views which must be obtained before any thing like a precise description can be given of the globe we inhabit, or of any portion of it. With regard to what belongs to Physical Geography, we must refer the reader to the articles Physical Geography, Mineralogy, Meteorology, &c. in this work. What belongs to Political or Historical Geography will be found under the names of the respective countries. The following article will be limited to a view of the progress of Geographical Discovery, and to a brief explanation of the principles of Mathematical Geography.

I.—VIEW OF THE PROGRESS OF GEOGRAPHICAL DISCOVERY.

There are many circumstances in the condition of man which connect him so closely with the globe which he inhabits, as to render absolutely necessary to his existence a knowledge of at least the neighbourhood of the spot where his lot is cast. It is from the earth that he must derive the means of subsistence and accommodation, the materials on which his industry is to be exerted, and those objects in the exchange of which commerce consists. In every stage of his progress, therefore, from barbarism to civilization, he must employ some attention and observation, in order to discover in what respects the objects with which he is surrounded are qualified to contribute to the supply of his wants, and to his comfort and convenience. Even while he roams the forest in the savage state, he must make himself acquainted with many circumstances, a knowledge of which is necessary either to give him success in the chase, or to direct him in retracing his steps to the place where he has fixed his dwelling. But it is not until men have united in society, and that neighbouring communities have begun to hold mutual intercourse, that those feelings and passions are effectually aroused which stimulate to the arduous pursuits of geographical discovery. Commerce and war, with the spirit of adventure which usually accompany them, have without doubt been among the first causes of geographical research. In the train of these have followed the workings of avarice and the aims of ambition. As the human mind has advanced in its career of improvement, curiosity, with an enlargement of views and desires, have been called into action; and voyages have been undertaken for the express purpose of discovering new countries and exploring unknown seas.

In tracing the effects which these causes have produced in the gradual increase of geographical knowledge, it will contribute to distinctness to keep in view a threefold division, which the subject naturally assumes, namely, *ancient* geography, extending from the earliest period of history down to the time when, the Roman empire having been overrun by barbarous nations from several quarters, Europe was overwhelmed in the darkness which preceded the revival of learning; the geography *of the middle ages*, extending from the revival of letters to the fifteenth century, when the discoveries of the Portuguese began to lay a wider foundation for the science; and *modern* geography, which embraces the most recent discoveries, and is progressively improving by the accessions which it is receiving from the labours and science of modern travellers and navigators.

The Phœnicians are the earliest commercial people of whose discoveries we have any correct accounts. This people seem first to have explored the coasts of the Mediterranean. Their navigators at length extending their voyages through the Straits of Gades, now called the Straits of Gibraltar, entered the Atlantic Ocean, and visited the western coasts of Spain and Africa. In many places to which they resorted they planted colonies; and sought, by instructing the inhabitants, in some measure, in their arts and improvements, to open a wider sphere for their commerce. The learned Bochart, led by the analogy between the Phœnician tongue and the oriental languages, has endeavoured to follow the tracks of the Phœnicians, both along the shores of the Mediterranean and those of the Atlantic. These analogies are not always sure guides; but there seems no reason to doubt that Cadiz was originally a Phœnician colony, and it is not likely that this was the only one formed by that enterprising people.

The Arabian Gulf, or Red Sea, offered to the Phœnicians another field of naval and commercial exertion, to the improvement of which the distance of Tyre, the emporium of their trade, was the only obstacle. This induced them to make themselves masters of Rhinocrura or Rhinocolura, the port in the Mediterranean nearest to the Red Sea. Commodities purchased in Arabia, Ethiopia, and India were landed at Elah, the safest harbour in the Red Sea towards the north; thence they were conveyed over land to Rhinocolura; and being there reshipped, they were carried to Tyre, whence they were distributed over the world.

The wealth and power which accrued to the Phœnicians from their being in the sole possession of the lucrative trade of the East, incited the Jews, their neighbours, under the prosperous reigns of David and Solomon, to desire a participation in its advantages. Their conquest of Idumea, which stretches along the Red Sea, put it in the power of Solomon to fit out a fleet; while his alliance with Hiram, king of Tyre, enabled him to command the skill of the Phœnicians for the conducting of the voyage. Passing through the Straits of Babelmandel, they carried on commerce in the Indian Ocean; and so distant were the countries to which they traded, that the voyage occupied no less than three years. But though the Jews thus for a time engaged in the pursuits of trade, yet the tendency of their institutions, which were expressly designed to preserve them a separate people, was unfavourable to the development of the commercial spirit which their monarchs wished to foster among them. This, joined with the division of the kingdom on the death of Solomon, proved fatal to their rising greatness as a commercial people, and excluded them from ranking among the nations who have contributed to the advancement of geographical knowledge. It is perhaps impossible to fix with certainty the limits which bounded the geographical researches of the Phœnicians, on account of the difficulty there is of assigning the precise places marked out by the names then given to the countries to which they traded. The length of time occupied in the voyage, and the nature of the cargoes brought home, with a few other circumstances of the same vague kind, are the only particulars afforded to direct us in the determination. Thus the country of Ophir, to which the Phœnicians navigated the ships of Solomon, must be ascertained by the facts that the voyage thither and homeward occupied three years, and that the cargo consisted of "gold and silver, ivory, and apes, and peacocks." Among the various opinions which have been entertained respecting the position of this distant country, the most probable appears to be that it was situated on the eastern coast of Africa, as far south as Sofala. To this quarter every indication seems clearly to point; and whatever objections may appear to stand in the way, in consideration of the remoteness of the region, and the difficulties to be encountered, these admit of being answered by a reference to the length of time required for the voyage, and to the wealth, naval skill, and ample resources, at the command of the monarchs engaged in the traffic.[1]

The Carthaginians, a Phœnician colony, retained in full vigour the commercial spirit of the parent state. They did not, however, attempt to divide with Tyre the wealth and power which she derived from the monopoly of the trade carried on in the Arabian Gulf. They directed their efforts to the opposite quarter, and sailing through the Straits of Gades, pushed their researches far beyond the bounds which had been reached by the mother country in this part of the globe. They visited not only all the coast of Spain, but likewise that of Gaul, and penetrated at length as far as the south-western coast of Britain, where they obtained tin from the mines of Cornwall or in traffic with the natives. Nor was it only towards the northward that they directed their efforts; they explored also the regions southward of the straits, and sailing along the western coast of Africa almost as far as the northern tropic, they planted colonies, as the Phœnicians of Tyre had formerly done, with a view to prepare the natives for carrying on commercial intercourse. The Atlantic Ocean was destined to conceal for ages from the inhabitants of the old world the immense regions which lie beyond it. But the Carthaginians extended the boundary of navigation westward by the discovery of the Fortunate Islands, now known by the name of the Canaries.

The enlargement of views gradually generated by this spirit of commercial enterprise led at length to voyages of which discovery was the special object. The circumnavigation of Africa was one of the earliest attempts of this kind made by the ancients. The direction which the coast takes beyond the Mediterranean on the one hand, and the Red Sea on the other, suggested the idea of a peninsula which it might be possible to sail round. This voyage was first undertaken by the Egyptians; a people exceedingly averse to engage in naval affairs, but who at this time were ruled over by Necho, a monarch whose active spirit prompted him to engage some Phœnicians to descend the Arabian Gulf, and, coasting along Africa, to endeavour to return by the Straits of Gades. Herodotus narrates in a few words the result of this enterprise, which was undertaken about six hundred and four years before the Christian era. He says, "the Phœnicians, setting sail from the Red Sea, made their way into the southern sea; and when autumn approached they drew their vessels to land, sowed a crop, and waited till it was grown; when they reaped it, and again put to sea. Having spent two years in this manner, in the third year they reached the pillars of Hercules, and returned to Egypt, reporting what does not find belief with me, but may perhaps with some other person; for they said that in passing Africa they had the sun on their right hand. In this manner Lybia was first known."

---

[1] The regions always spoken of in Scripture as the most remote with which the Hebrews and Phœnicians were acquainted are, Tarshish, Ophir, the Isles, Sheba, and Dedan, the River, Gog, Magog, and the North. Without entering into any discussion, we may give what appear to be the most probable conclusions with regard to the positions of the countries to which these names were applied. Tarshish is a country from which two voyages are spoken of in Scripture as being made; one by the Mediterranean, bringing iron, silver, lead, and tin, the produce of Spain and Britain; the other by the Red Sea, bringing gold, ivory, and other productions of tropical Africa. These two voyages, though at first sight they appear incongruous if supposed to be made to the same country, may be reconciled by supposing that Tarshish is fundamentally Carthage, which monopolized almost entirely the commerce of Spain and Britain, and was the medium through which the commodities of the west were distributed; and that the name of this great African metropolis was extended to the whole of the continent of Africa. The Isles are the whole southern coasts of Europe, consisting either of real islands or peninsular tracts. Sheba is the southern portion of that part of the coast of Arabia which borders on the Red Sea; while Dedan lies upon the opposite coast, that borders on the Persian Gulf. These countries rose to commercial importance in consequence of the valuable commodities which were imported into the former from the African coast, and into the latter from India. Thence arose the traffic carried on by "the companies of Sheba," or caravans, and by "the travelling companies of Dedanim." The River was the name always applied to the Euphrates. Gog, Magog, and the North, appear to be the high tableland in the interior and north of Asia Minor, Phrygia, Galatia, Cappadocia, and Paphlagonia, regions in which may be recognised the peculiarly rude and formidable aspect which belonged to the countries to which in ancient times the names in question were applied. (See *Encyclopædia of Geography*, by H. Murray, Esq.)

This passage has given rise to much controversy among the learned. But the voyage here so briefly described does not seem to involve any impossibility, notwithstanding the then infant state of navigation; and the circumstance which the historian objects to as incredible is the very point which, from its coincidence with what we know should have happened, renders the story more worthy of belief.

Xerxes king of Persia, according to Herodotus, gave a similar commission, about four hundred and eighty years before the Christian era, to one of his satraps, named Sataspes, who, for a heinous offence, had been condemned to die. If successful in the accomplishment of this voyage, Sataspes was to escape a cruel death; but the difficulties were too great to be surmounted by a navigator brought up amidst the luxury and indulgence of the Persian court. Having procured from Egypt a vessel and crew, he passed through the Straits of Gades, entered the Atlantic Ocean, and, bending his course towards the south, coasted the continent of Africa, until, after several months, he probably reached the coast of Sahara. The frightful and desolate shores along which he sailed, and the tempestuous ocean which beat against them, combined to fill his mind with alarm, and to shake his resolution. He retraced his course to the straits; and hoping perhaps that the labours he had undergone in the partial accomplishment of the task imposed on him would be accepted by his royal master as a sufficient atonement for his offence, or that the offence itself might in a great measure be forgotten, he returned home and presented himself before Xerxes. The cause which he assigned for the failure of the ultimate object of his mission was, that he had encountered a sea so full of herbage that his passage was completely obstructed. This reason (the grounds of which have never been satisfactorily explained, though it *has* been alleged that obstacles of this description occur in that part of the sea which lies between the Cape Verd Islands, the Canaries, and the coast of Africa) appeared so ridiculous to Xerxes, that he ordered the sentence of death by crucifixion, which had been pronounced upon Sataspes, to be immediately executed.

But the most celebrated voyage of antiquity undertaken for the purpose of discovery was the expedition under Hanno, fitted out by the authority of the senate of Carthage, and at the public expense, and that with the view of attempting a complete survey of the western coast of Africa. Of all the voyages performed by the Phœnicians and Carthaginians, this is the only one of which we have an authentic narrative. Mercantile jealousy prevented these two great commercial states from communicating to other nations the knowledge which they acquired of the remote regions of the earth; and from this cause, when the maritime power of the former was annihilated by Alexander's conquest of Tyre, and the empire of the latter was overthrown by the Roman arms, all monuments of their great skill in naval affairs appear in a great measure to have perished. Even the account of the voyage of Hanno (*Periplus Hannonis*) has been considered by its learned editor Mr Dodwell as a spurious work. But the arguments of M. de Montesquieu and of M. de Bougainville appear fully to establish its authenticity, which the learned world now generally admit.

Hanno set sail with a fleet of sixty vessels, so constructed that, according to the mode of ancient navigation, he could keep close in with the coast. We are told that, in twelve days after leaving the Straits of Gades, he reached the island of Cerne; that proceeding thence, and following the direction of the coast, he arrived, in seventeen days, at a bay, which he called *The West Horn.* From this he advanced to another bay, which he named *The South Horn.* The objects which are described as having been seen by Hanno in his progress belong to tropical Africa. But in attempting to ascertain the places which he visited, or the utmost distance which he sailed southward, much difficulty and uncertainty are experienced. Bougainville supposes Hanno to have reached the Gulf of Benin, and contends that this limit, distant as it is, cannot be regarded as beyond what may be conceived to have been accomplished by the most skilful navigator of antiquity. Major Rennell shortens the distance considerably by conceiving the voyage to have been extended no further southward than Sherbro Sound, a little beyond Sierra Leone. He thus obtains the advantage of avoiding a difficulty involved in the hypothesis of M. de Bougainville; namely, the supposition of ancient ships having sailed upwards of seventy geographical miles in a day. At the same time, the arguments which support the one hypothesis are equally applicable to the other.

According to the views of M. Gosselin, however, the voyage must be confined to much narrower limits southward than even those assigned by Major Rennell. He supposes it to have terminated about the river Nun; an opinion which he supports by alleging that, in such a voyage, the progress must necessarily have been slow. The Carthaginian navigator had to encounter all the obstacles and dangers incident to a course held along a shore, and in a sea, which were equally unknown. He must have found himself impeded by the requisite examination of every part of the coast, as well as by the many precautions which the safety of the fleet under his command must have rendered constantly necessary. With regard to the circumstances given in the narrative which appear to point to tropical Africa, M. Gosselin supposes that the same aspect of life and nature may, at that distant period, have belonged to Morocco, then thinly peopled by the rude native tribes, which is now specially characteristic of more southern regions.

Amidst such diversity of opinion among the learned, it is not easy to decide in reference to a subject beset with so many difficulties. If we assume either of the more remote distances assigned for the termination of the voyage, Cerne must be identified with the isle of Arguin; and, on Major Rennell's hypothesis, the Gulfs of Bissago and Sherbro present those numerous islands described by Hanno, to which there are no islands corresponding on any other part of the coast. On the whole, however, the most limited distance seems preferable, if we admit that part of M. Gosselin's hypothesis which assigns to Morocco features of man and of nature that are usually held to be characteristic of tropical Africa.

The circumnavigation of Africa was an enterprise which in ancient times not only called forth the naval efforts of the most powerful maritime states, but which also awakened the ambition of private adventurers. Eudoxus, a native of Cyzicus, being sent on a mission to Alexandria, at that time the seat of naval enterprise and geographical knowledge, his ardent mind, naturally biassed to these pursuits, was aroused to action by the spirit which prevailed in that city. He began his career under the auspices of Ptolemy Euergetes, the reigning Egyptian monarch, who fitted out a fleet, and placed it under his command. According to the destination assigned him, Eudoxus descended the Arabian Gulf, and proceeded probably as far as the southern shore of Arabia. Thence he appears to have returned, after a prosperous voyage, with a valuable cargo of aromatics and precious stones. But of this wealth he appears to have been deprived by Euergetes. After the death of this monarch, which in a short time took place, his widow Cleopatra sent Eudoxus on another voyage, in the course of which he was driven by unfavourable winds on the coast of Ethiopia, where he was kindly received by the inhabitants, and carried on with them an advantageous traffic. After other vicissitudes of fortune, he was induced by circumstances which occurred in his adventurous life to leave the court of Egypt, and repair to the commercial city of Cadiz, in Spain, and there to fit out an expedition for the purpose of African discovery. At Massilia (Marseilles), and other maritime places through which he passed on his way to Cadiz, he took care to make known his views and hopes of success, and to invite all who were actuated by any spirit of enterprise to accompany him. He succeeded in fitting out a ship and two large boats; on board of which he carried not only goods and provisions, but artisans, medical men, and even players on musical instruments. This was no doubt proceeding on a magnificent scale. But his crew was ill calculated to second his bold undertaking. To avoid the danger of stranding, Eudoxus was anxious to keep the open sea. His companions, however, alarmed at the swell, forced him to adopt the usual mode then followed of sailing along the shore; a measure which led to the disaster which he had anticipated. With one vessel of a lighter construction, on board of which was put the more valuable part of the cargo, Eudoxus pursued his voyage until he reached a part of the coast inhabited by a race of people that appeared to him to speak the same language with those whom he had found on the opposite side of the continent. Judging from this circumstance that he had ascertained the main object of his voyage, he returned and endeavoured to obtain the assistance of Bocchus, king of Mauritania. Suspecting, however, treachery on the part of that monarch, he again had recourse to Spain. Here he was again successful in equipping another expedition, consisting of one large vessel fitted for the open sea, and another of smaller size for the examination of the coast. This was a judicious preparation for the accomplishment of the object in view; but with regard to the issue of the voyage no accounts of any authority have been preserved.

Such are the leading circumstances connected with the voyages of Eudoxus, which are narrated by Strabo; and, notwithstanding the scepticism and severe criticisms of that geographer, there is really nothing to which the candid reader can reasonably refuse his belief. Prejudices, founded, for the most part, on his own want of information, led Strabo to treat likewise as fabulous the relation of the only ancient voyage having Europe, and more particularly the British isles, for its object, of which we have any detailed account.

Pytheas, a Massilian navigator, undertook an expedition about three hundred and twenty years before the Christian era. He steered northward; and after examining the coasts of Spain and Gaul, he sailed round the island of Albion; and, stretching still farther to the north, he discovered an island, the *Ultima Thule* of the ancients. What island this was the learned are not agreed. It has been supposed to be the modern Iceland; but this implies too great an extent of open sea for an ancient navigator to traverse; and besides, six days, the period during which he is said to have navigated to the northward of Albion before he made his discovery, are too short a time to admit of his reaching Iceland. Others, amongst whom is Malte-Brun, have considered Jutland as Ultima Thule. But it should be kept in view that Pytheas uniformly regarded Thule as British, a character which he could scarcely conceive to belong to Jutland, seeing he could have reached that peninsula only by a long course along the coasts of Germany, which must have impressed on his mind the idea that he had left far behind him every thing belonging to Britain. On the whole, Shetland seems best entitled to be considered as the ancient Thule, and suits well with the appellation which Pytheas gives it, when he expressly calls it the "furthest of the Britains."

Strabo endeavours to throw discredit on the statements of Pytheas, by starting objections long known to be of the most groundless description; and it is an advantage which the traveller and navigator possess who describe faithfully the grand features of nature, that, however prejudice may dim their reputation for a time, yet will their accuracy as well as veracity at length, in the progress of knowledge, appear, and secure for them the respect and applause of mankind. At the same time, it must be admitted that, in describing what he saw beyond his Ultima Thule, the statement given by Pytheas, as reported by Strabo, assumes a somewhat fabulous character. He asserted, it seems, that beyond Thule there commenced what was neither earth, sea, nor air, but a confused blending of all the three. But even here some allowance is to be made for the workings of imagination under very peculiar circumstances, and a readiness, not unnatural, to believe reports which represented him to have reached the extremity of the habitable globe. If his language is not too literally interpreted, it will be found to convey a strongly figurative, but not altogether imperfect, description of the state of the sea and sky in these climes, which have been so little favoured by nature.

The conquests of Alexander the Great, by making known the East, enlarged the bounds of geographical knowledge. Though the course of his expedition was for the most part by land, his mind was equally intent on commerce and maritime discovery. Checked as he had so long been in the career of his victories by the opposition and efforts of the republic of Tyre, he had an opportunity afforded him of observing the vast resources of a maritime power, and at the same time of forming a judgment respecting the immense wealth to be derived from commerce, especially from that carried on with India, which he found to be wholly in the hands of the Tyrians. With a view to secure this commerce, as soon as he had completed the conquest of Egypt, he founded the city of Alexandria, and thus established for it a station preferable in many respects to Tyre. After his final victory over the Persians, his march in pursuit of Bessus, who had carried off Darius into Bactriana, often led him near to India, and among people accustomed to much intercourse with it, from whom he learned many things concerning the state of the country, that served so to confirm and inflame a desire which he had long cherished of extending his dominion over those regions, that he was induced to conduct his army from Bactria, for the purpose of invasion, across that ridge of mountains which form the northern barrier of India. After passing the Indus, Alexander directed his march to the Ganges, which, from the accounts he heard of it, and of the countries through which it flows, he was eager to reach. The route which he found it necessary to follow, in consequence of being successively engaged in hostilities with various native princes, led him through one of the richest and best peopled countries in India, now called Punjab. In his ultimate object, however, he failed.

His march being performed during the rainy season, his troops had already suffered so much, that notwithstanding the high degree in which he possessed all those qualities that secure an ascendency over the minds of soldiers, he was unable to persuade them to advance beyond the banks of the Hyphasis, the modern Beyah, which was accordingly the utmost limit of Alexander's progress in India.

By this expedition, Alexander first opened the knowledge of India to the people of Europe; and as he was accompanied, wherever he went, by skilful surveyors, Diognetes and Baeton, who measured the length and determined the direction of every route taken by the army, he furnished a survey of an extensive district of it, more accurate than could have been expected from the short time he remained in that country. The memoirs drawn up by his officers likewise afforded to Europeans their first authentic information respecting the climate, the soil, the productions, and the inhabitants of India.

Though Alexander did not penetrate to the Ganges, his expedition prepared the way to the knowledge of that magnificent stream. For soon after, Seleucus, one of his successors, sent Megasthenes as his ambassador to Palibothra, the capital of a powerful nation on the banks of the Ganges. The site of Palibothra was probably the same as that of the modern city of Allahabad, at the junction of the river Jumna with the Ganges. This embassy brought new and opulent provinces of India into view, an acquaintance with which served to raise still higher the idea generally entertained of the value and importance of the country.

The island *Taprobane*, so celebrated among the ancients, which appears, notwithstanding some great mistakes with respect both to extent and position, to be the modern Ceylon, seems not to have been known in Europe even by name before the age of Alexander. In consequence, however, of the enlightened and active curiosity with which he explored every country which he subdued or visited, some knowledge of it was at length obtained; and, after his time, it is mentioned by almost every ancient geographer.

Whilst Alexander was attempting to penetrate into India, a numerous fleet was assembled by officers whom he had left on the banks of the Hydaspes, the modern Behat or Chelum, with orders to build and collect as many ships as they could. The destination of this fleet was to sail down the Indus to the ocean, and from its mouth to proceed to the Persian Gulf, with a view of opening a communication between India and the centre of his dominions.

When Alexander reached the banks of the Hydaspes on his return, he committed the conduct of this expedition to Nearchus. The voyage down the Indus derived splendour from the greatness and magnificence of the armament, which consisted of an army of a hundred and twenty thousand men, and two hundred elephants, and of a fleet of nearly two thousand vessels. Alexander himself accompanied Nearchus in his navigation down the river, with one third of the troops on board; whilst the remainder, in two divisions, one on the right and the other on the left of the river, accompanied them in their progress. Having reached the ocean after the lapse of nine months, Alexander left Nearchus and his crew to pursue their voyage, and conducted his army back by land to Persia. A coasting voyage of seven months brought Nearchus, with the fleet, in safety, up the Persian Gulf into the Euphrates. It was at the mouth of the Indus that the Greeks witnessed for the first time, and that with astonishment and terror, the ebb and flow of the sea; a phenomenon scarcely perceptible in the Mediterranean, to which their navigation had formerly been confined. In the progress of the voyage they were also struck with surprise on observing phenomena belonging to the midsummer of the tropics. At noon objects were observed to project no shadows, or to project small shadows declining to the south. Their attention was still further attracted by the new appearance of the sky. Stars which they had been accustomed to see high in the heavens were now seen near the horizon. Some stars to the north disappeared, while other stars formerly invisible were seen in the south.

The opening of a communication between the Red Sea and the Persian Gulf was with Alexander another great object of ambition. But though with this view he seems to have sent expeditions down both seas, he failed in his attempts to accomplish this project.

Among the Romans, navigation and commerce, the handmaids of geographical science, were never made objects of pursuit, except in so far as they were found to be necessary to forward their schemes of universal dominion. Their conquests opened indeed the west, as those of Alexander had made known the east; and it might be truly said of that great people, that as they were the conquerors, so they were the surveyors of the world. Every new war produced a new survey and itinerary of the countries which were the scenes of action; so that the materials of geography were accumulated by every additional conquest. Some fragments of the itineraries thus composed still remain. The most memorable is that which bears the name of Antoninus, and which may be described as a mere skeleton road-book, exhibiting nothing more than the names of places, and their distances from each other. The Jerusalem Itinerary, which details minutely the route from Bordeaux to that holy city, is of the same description.

A more remarkable monument, however, is the *Peutingerian Table*, which forms a map of the world, constructed on the most singular principles. The map is twenty feet long and only one foot broad, so that we can easily conceive how incorrectly the proportion of the different parts is exhibited. Along the high road which traverses the Roman empire in the general direction of east and west, objects are minutely and accurately represented; but of those objects which lie to the north and south of it, only some general notion is conveyed. The Peutingerian Table serves as a specimen of what were called *Itinera Picta*, the "painted roads" of the ancients, intended for the clearer direction of the march of their armies.

While the Romans by their surveys contributed much to increase the mass of materials out of which the structure of geographical science was to be reared, they never attempted themselves to combine these materials into one harmonious system. They imbibed in no degree the commercial spirit of the great maritime states of the ancient world, Carthage, Greece, and Egypt, which their valour and discipline obliged to submit to their dominion. But whilst the trade of the conquered countries continued to be carried on through nearly the former channels after they were reduced to the form of Roman provinces, the wealth accumulated in the capital of the world gave rise to a demand for luxuries of every description. This, combined with the comparative peace and security which for a long time prevailed after the complete establishment of the Roman dominion, gave new vigour to commercial enterprise. Alexandria continued the great centre of naval affairs. Obstacles which in the time of Alexander were deemed insurmountable, were completely overcome. Trade with India through Egypt acquired new energy, and was carried on to a greater extent. Continued intercourse with the shores of India at length made known to navigators the periodical winds which prevail in the Indian Ocean; and taking advantage of these, pilots were emboldened to abandon the slow and dangerous course along the coasts, and to make the open sea their highway. Their course was from Ocelis, at the mouth of the Arabian Gulf, to Nelkunda (Nelisuram), on the western shores of the Indian continent (the coast of Malabar), which seems to have been the utmost limit of the ancient navigation in that quarter of the globe. The extensive regions which stretch beyond this to the east were very imperfectly known by the reports obtained from a few adventurers who visited them by land.

If we now bring into one view the amount of information possessed by the ancients respecting the habitable globe, we shall find that it was extremely limited. It was at those places on the earth where the human mind displayed greatest activity and enterprise that this knowledge was naturally accumulated. Proceeding from these stations, the boundary which separated the known from the unknown part of the world was gradually enlarged; but the regions comprehended within it constituted still but a small portion of the whole. In Europe the extensive provinces in the eastern part of Germany were but little known, while the whole of that vast territory which now forms the countries of Denmark, Sweden, Prussia, Poland, and Russia, was buried in the deepest obscurity. The inhospitable and dreary climes within the arctic circle were yet unexplored. In Africa little was known beyond the countries stretching along the Mediterranean Sea, and those bordering on the western shore of the Arabian Gulf. In Asia the rich and fertile countries beyond the Ganges, whence the commerce of modern times has drawn the most valuable commodities for the comfort and embellishment of civilized society, were known, if known at all, only by the most vague and uncertain reports. The immense regions on the north occupied by the wandering tribes called in ancient times by the general names of Sarmatians or Scythians, and which are now inhabited by various tribes of Tartars, and by the Asiatic subjects of Russia, seem never to have been penetrated. Add to this, that the fertile and populous regions within the torrid zone were imagined to be uninhabitable; and we have ample proof that the geography of the ancients was very imperfect.

Having thus far given a succinct view of the progressive steps by which the earth's surface, considered merely as tracts of territory inhabited by men, gradually became known, it will be proper next to trace briefly the advances made towards arranging into a systematic form the materials accumulated. Science required that the relative positions of places, with their distances from each other, should be ascertained in such a manner as to furnish fixed principles on which the whole, or any portion, of the surface of the earth might be represented or delineated with due regard to its figure and dimensions.

The first rude attempt made by the early geographers to determine the position of places appears to have depended on the division of the earth into *climates*, distinguished by the species of animals and plants produced in each. Thus the appearance of the negro, the rhinoceros, and the elephant, suggested to them the line of division where the torrid zone began towards the north, and ended towards the south. But instead of this very vague method, another was soon adopted, which consisted in observing at places the length of the longest and shortest day. This was determined with some accuracy by means of a *gnomon*, a method of observation much used by the ancients. An upright pillar of a known height being erected on a level pavement, by observing the lengths of the meridian shadows, they were enabled to trace the progress of the sun from tropic to tropic. The most ancient observation with the gnomon which we meet with is that of Pytheas, in the days of Alexander the Great. Pytheas observed at the summer solstice at Marseilles, that the length of the meridian shadow was to the height of the gnomon as $213\frac{1}{8}$ to 600; an observation which makes the meridian altitude of the sun at Marseilles on that day 70° 27′. The merit of the invention of the gnomon in Greece is ascribed to the astronomical school of Miletus, and particularly to Anaximander and Anaximenes. There is reason, however, to believe that this method of observation was originally invented by the Egyptians; and that Thales, who travelled into Egypt, carried thence the knowledge of it into Greece. It has even been conjectured that the Egyptian pyramids and obelisks were intended for the same purpose with the gnomon; and, though it would be extravagant to imagine that this was their sole use, this opinion appears to be countenanced by the fact of their being placed in the direction of the four cardinal points.

The determination of the length of the meridian shadow at the solstices for different parts of the earth, by observations made with the gnomon, is important as being the first step towards connecting geography with astronomy; and, when combined with just conceptions of the globular figure of the earth, leads, by a simple train of thought, to the notion of latitude by which the position of a place is fixed relatively to north and south. The position with regard to east and west is the only other element necessary for fixing the absolute situation of the place on the surface of the earth. It might have been supposed not to be more than a reflecting mind could easily accomplish, to reach the conception of both these elements, and to apply them to use. Yet so slow was the progress towards the apprehension of the principles on which an accurate system of geography might be founded, that from the days of Thales and his immediate successors, who flourished in the sixth century before the Christian era, there appears to have been little done for the improvement of geography, as a science, until the establishment of the famous astronomical school of Alexandria. Pythagoras had indeed maintained the true system of the world, by placing the sun in the centre, and giving the earth both a diurnal and annual revolution; but this doctrine was so much in advance of the age in which he promulgated it, that it was soon lost sight of.

Eratosthenes was the first who reduced geography to a regular system, and laid its foundations on clear and solid principles. Under the patronage of the Ptolemies, he had access to the materials collected by Alexander, his generals and successors, as well as to the immense mass of documents accumulated in the Alexandrian library. At an early period of the history of astronomical science, the vulgar opinion that the earth is a flat surface, with the heavens resting upon it as a canopy, was rejected; but it was not at once that distinct conceptions of its globular figure were acquired. It was only as astronomical observations increased that the doctrine of its sphericity was fully established. This point had been gained when Eratosthenes began his labours; and what he endeavoured to accomplish was to delineate, in strict conformity with this principle, the known parts of the earth's surface.

With this view, founding his system on the use of the gnomon, he supposed a line to be traced through certain places, in all of which the longest day was known to be exactly of the same length. This line would evidently be a parallel to the equator. But though his method was correct in principle, the want of accurate observations rendered it uncertain in practice. The line was supposed to comprise all the leading positions which lay near it, though they did not actually come within its range. Its western extremity was the Sacred Promontory of Iberia (Cape St Vincent); thence it passed through the Straits of Gades. Proceeding eastward, it passed through the Sicilian Sea, and near the southern extremity of the Peloponnesus, and was continued through the island of

Rhodes, and the Bay of Issus; whence entering Cilicia, and crossing the Euphrates and the Tigris, it was extended to the mountains of India, and terminated at the remote city of Thinæ, situated on the Eastern Ocean. The parallel thus drawn was understood to pass through all those places where the longest day was fourteen hours and a half. It stretched the whole length of what was supposed to be the habitable world, and measured about 70,000 stadia; a distance corresponding, according to the estimate of Eratosthenes, to about 140 degrees, which is rather more than one third of the circuit of the globe.

This first parallel drawn through Rhodes was ever afterwards preferred as the basis of ancient maps; inasmuch as it was traced through the middle of the Mediterranean, along the coasts of which were situated the principal nations of antiquity. Following out the same happy thought which he had thus successfully made the groundwork of his system, Eratosthenes was induced not only to trace other parallels at certain intervals from the first, as one through Alexandria, another through Syene, and a third through Meroe; but also to trace, at right angles to these, a *meridian*, passing through Rhodes and Alexandria southward to Syene and Meroe. As the progress which he thus made towards the completion of what he had so skilfully conceived, naturally tended to enlarge his ideas concerning geographical science, he attempted what seemed a still more difficult undertaking, namely, to determine the circumference of the globe by the actual measurement of a segment of one of its great circles. The method he pursued has already been pointed out in the article Astronomy, page 790. There is a difference among ancient authors respecting the result obtained by Eratosthenes. The great majority, however, state it to be 252,000 stadia, which give exactly 700 stadia for a degree of the equator, and 555 stadia for the degree of longitude upon the parallel drawn through Rhodes.

The knowledge of the circumference of the earth is a necessary element in the construction of maps; and hence the most eminent of the ancient astronomical geographers made repeated endeavours to determine it with accuracy. Possidonius, by an astronomical observation, determined the arc of the meridian between Rhodes and Alexandria to be a forty-eighth part of the whole circumference. With regard to the distance between these two places, 5000 stadia were the reputed distance; but Eratosthenes had made it only 3750 stadia upwards of 170 years before, and betwixt these two Possidonius had to make choice. The former number gives 240,000 stadia for the whole circumference, the latter 180,000 stadia. Of this last result, which gives 500 stadia for a degree of the equator, Possidonius is reported by Strabo to have approved. For want of the knowledge of the true length of the stadium, it is now impossible to judge of the actual quantity assigned either by Eratosthenes or Possidonius as the measure of the earth's circumference; but the great uncertainty about the distance between the points of observation in the case of the determination of the latter astronomer renders his conclusion of no value.

Notwithstanding the soundness of the principles which had now been laid down for the delineation of the globe, much remained to be done, in the way of observation, before an accurate representation of the whole, or a portion of the earth's surface, could be given. Both the latitudes and longitudes of the ancients are erroneous; more especially the latter. This is what might be expected at that early period. But in setting out from the Sacred Promontory of Iberia, the meridian of which the ancients made their first meridian, the errors in longitude accumulate, as we advance eastward, with a regularity, as well as rapidity, which is very surprising. The regularity of their increase induced M. Gosselin to conclude that they were to be attributed, not to the imperfection of independent observations, but to some general cause, which he endeavoured to assign by imagining that Eratosthenes had access to some early map, found probably by Alexander or his generals in some country in the East, where astronomy had been successfully cultivated; and that misapprehensions respecting the principle of delineation employed, which M. Gosselin supposes to have been that on which the plane chart is constructed, had led him into a regular system of errors. In the plane map the length of a degree of longitude is supposed to be the same at all distances from the equator. By taking for granted that Eratosthenes took his distances from a map of this kind, on which the parts of the globe had been accurately laid down, but that he divided the stadia expressing these distances, not by 700, the number of stadia in a degree at the equator, as he ought to have done, but by 555, the number corresponding to the parallel of Rhodes, M. Gosselin obtains results which have a wonderful coincidence with the positions actually given by Eratosthenes. These results, however, are deduced from a hypothesis which is unsupported by any evidence, except what may be supposed to arise from this coincidence. A more probable solution seems to be that Eratosthenes determined his longitudes from the itinerary measures, which he reduced to degrees at the rate of 700 stadia to a degree at the equator, and of 555 to a degree at the parallel of Rhodes; and that the errors are the consequences of the exaggerated accounts which merchants and travellers of that age gave of the distances over which they passed;—their exaggerations, of course, bearing some proportion to the length and hardships of the journeys undertaken.

The knowledge as yet possessed by geographers with regard to the outline of the habitable globe was far from being such as to enable them to delineate it with any degree of precision. This circumstance, combined with the unavoidable errors in latitude and longitude, produced very great distortions in the representations given of the countries on the surface of the globe. Under the guidance of sound principles of science, however, it was now certain that these imperfections would gradually disappear.

The improvements introduced into geography by Eratosthenes were perfected in principle by Hipparchus. This celebrated astronomer, who flourished between a hundred and sixty and a hundred and thirty-five years before the Christian era, was the first who undertook the arduous task of forming a catalogue of the stars, and fixing their relative positions. His object was to transmit to posterity a knowledge of the state of the heavens at the period of his observations. The extremities of the imaginary axis round which the heavens perform their diurnal revolution suggest two fixed points by which the position of the great circle of the celestial sphere called the equator is determined. If a great circle be supposed to pass through these points and any star, the position of the star will be ascertained if we measure in degrees and parts of a degree the arc of the meridian circle intercepted between the star and the equator, and also the arc of the equator intercepted between a given point in it, and the meridian circle passing through the star. Upon this principle did Hipparchus arrange the stars according to their places in the heavens, a work in which he appears, however, to have been in some measure anticipated by Timocharis and Aristillus, who began to observe about two hundred and ninety-five years before the Christian era. The great improvement which he introduced into geography consisted in this, that he applied to the determining of the position of any point on the surface of the earth the same artifice which he had already so happily introduced in the arrangement of the constellations; and thus furnished the means of ascertaining the relative situations of places with a precision which no itinerary measurements could possibly attain. If we suppose the earth to be a globe concentric with the celestial sphere, and intersected by the planes of the celestial equator and meridian, the principle on which the application of this artifice to the terrestrial sphere depends becomes at once obvious. Hipparchus made a considerable number of observations of latitude, and pointed out how longitudes might be determined by observing the eclipses of the sun and moon. Great as this improvement was, its importance seems not to have been duly estimated until the days of Ptolemy; for none of the intermediate authors, such as Strabo, Vetruvius, and Pliny, have given the least hint of the latitude and longitude of any one place in degrees and minutes, though all of them have given minutely the geographical position of places according to the length and shadows of the gnomon. Strabo, indeed, even justifies his neglect of the astronomical principles introduced by Hipparchus. "A geographer," says he, "is to pay no attention to what is out of the earth; nor will men engaged in conducting the affairs of that part of the earth which is inhabited, deem the distinction and divisions of Hipparchus worthy of notice."

The true principles of geography being pointed out by the application of latitude and longitude to places on the earth, the way was opened for the improvement of maps, which, with the single exception of the map drawn by Eratosthenes, had hitherto been little more than rude outlines and topographical sketches of the different countries.

No maps more ancient than those formed to illustrate Ptolemy's geography have reached modern times; but the earliest of which there is any account are those of Sesostris, of whom it is said, that having traversed great part of the earth, he caused his marches to be recorded in maps; and that he gave copies of these maps not only to the Egyptians, but to the Scythians, whose astonishment he thus greatly excited.

Some have imagined that the Jews made a map of the Holy Land when they gave the different portions to the nine tribes at Shiloh. For on that occasion, as we are informed by the sacred historian, men were sent "to walk through the land, and to describe it:" and when they had accomplished the object of their mission, by describing "it by cities into seven parts, in a book," they returned unto Joshua. What is here said, however, does not fully determine whether their mensuration of the land was only recorded in numbers, or regularly projected and digested into the form of a map.

The first Grecian map on record is that of Anaximander, mentioned by Strabo, which some have conjectured to have been a general map of the then known world. It has further been imagined to be the same with that referred to by Hipparchus under the designation of *The Ancient Map*, and which in some few particulars he preferred to that of Eratosthenes.

But some idea of the nature of the maps of those early days will be best obtained from the map of Aristagoras, king of Miletus, which is minutely described by Herodotus. The historian tells us that this map, which was traced on brass or copper, Aristagoras showed to Cleomenes, king of Sparta, in order to induce him to attack the king of Persia, even in his palace at Susa, for the purpose of restoring the Ionians to their ancient freedom. It contained the intermediate countries to be traversed in that march. We must not interpret, however, the words of Herodotus too literally, when he describes it as containing "the whole circumference of the earth, the whole sea or ocean, and all the rivers." Keeping in view the state of geography at that period, it may justly be concluded, that notwithstanding this pompous form of expression, *the sea* meant only the Mediterranean, and therefore *the earth* or land the coasts of that sea, and more particularly Asia Minor, extended towards the middle of Persia: by *the rivers* must be meant the Halys, the Euphrates, and the Tigris, which Herodotus mentions as necessary to be crossed in the expedition in question. The map contained one straight line, called the *royal highway*, embracing all the stations or places of encampment between Sardis and Susa, so that it was properly an itinerary.

The principle on which Eratosthenes constructed his map we have already considered. With regard to its extent, it seems to have contained little more than the states of Greece, and the dominions of the successors of Alexander, digested from the surveys of the marches of that great general. He had some faint idea respecting the western parts of Europe, which he had acquired from the voyage of Pytheas; but not such a conception as to enable him to delineate their outline on a chart. According to the report of Strabo, he was quite unacquainted with Spain, Gaul, Germany, and Britain, he was equally ignorant of Italy, the coasts of the Adriatic, Pontus, and of all the countries toward the north. His errors with regard to the distances of places were in some instances enormous. The distance of Carthage from Alexandria he represents at 15,000 stadia, instead of 9000.

It was not until Ptolemy commenced his labours that the improvements pointed out by Hipparchus were effectually applied to perfect the system which Eratosthenes had so happily begun. Ptolemy composed his system of geography, which escaped amidst the general wreck that consumed so many other ancient books of science, in the reign of Antoninus Pius, about 150 years after the opening of the Christian era. At this period the Roman empire had reached its utmost extent, and all the provinces had been surveyed, and were well known. The materials then in existence, and in the possession of Ptolemy for completing his great work, were the proportions of the height of the gnomon and its shadow, at the time of the equinoxes and solstices, taken by different astronomers; calculations founded on the length of the longest days; the measures or computed distances of the principal roads contained in the surveys and itineraries; and the various reports of travellers and navigators, whose determinations of the distances of places often rested, however, on no better foundation than hearsay and conjecture. Among these various particulars, there evidently existed considerable differences in point of authority. But Ptolemy undertook the difficult and laborious task of comparing, and reducing into one system, which should possess the order and beauty of science, this apparently incongruous mass. He converted and translated the whole into a new mathematical language, expressing in degrees and minutes the latitude and longitude of each place, according to the principles laid down by Hipparchus, but which had been allowed by geographers to lie useless for upwards of two hundred and fifty years. It is in Ptolemy's work, which consists of eight books, that we find for the first time the mathematical principles of the construction of maps, both general and particular, as well as of several projections of the sphere.

Notwithstanding that the light of accurate science thus directed the steps of the first geographer of antiquity, he was far from reaching the precision at which he aimed. This arose from the imperfection of the original materials upon which his work is based in reference to its details. With regard to the remoter boundaries of the then known world, in all its quarters, a wonderful advancement in knowledge had been made since the days of Eratosthenes and of Strabo. But still that additional information was not fitted to make up for the want of astronomical observations, by which alone accuracy could be secured. Besides, in relation to places situated beyond the limits of the Roman empire, and therefore out of the range alike of astronomers and surveyors, it was almost impossible for Ptolemy not to commit mistakes. Thus his errors arose from the ignorance of the age; and are of such a character as to admit of being removed only as opportunities are afforded of obtaining the requisite data by the strict application of the principles derived from mathematical and astronomical science.

Ptolemy adopted the measure of a degree at 500 stadia, according to the standard of Possidonius, instead of following the measurement of Eratosthenes, which gives 700 stadia to a degree. But M. Gosselin has accused him of an error of a more serious kind; because, if really committed, it would have indicated a strange neglect of what a geographer should make his first care. This error consists in assuming one measure for the degree of latitude (the measure of Eratosthenes, 700 stadia) and another for the degree of longitude at the equator. Such a hypothesis would evidently be inconsistent with the globular figure of the earth. It may reasonably be doubted, however, whether M. Gosselin's accusation is well founded; for, though it seems supported by the fact, that while Ptolemy has changed materially all the longitudes of Eratosthenes, the latitudes along the great line remain the same, and are in general correct, this circumstance may be accounted for sufficiently from other causes. Rhodes, and several other points of this great line, were fixed with regard to latitude by observations approximating to the truth, while the elements for determining the longitudes were derived entirely from the itineraries. To the north and south of the great central line, which alone was fixed upon sound data, errors in latitude accumulate as rapidly as those in longitude are found to do in proceeding eastward.

One of the most remarkable errors in the geographical work of Ptolemy is the great length assigned to the Mediterranean. Reckoning from the Straits of Gades to the bottom of the Bay of Issus, where Alexandretta, or Scanderoon, now stands, he makes the difference of longitude no less than sixty-two degrees, which is upwards of twenty and a half degrees above the truth. This amazing error, which affected all our maps more or less until the beginning of the last century, was produced in consequence of his having put too much confidence in the supposed surveys of different persons of reputation recorded by Strabo, and who appeared to confirm the accuracy of each other's computation. According to their united testimony, the whole length of the Mediterranean was about 26,500 stadia, which, being converted into degrees of longitude according to the method of Ptolemy, of allowing 400 stadia to a degree of longitude on the parallel of Rhodes, give about 66° 15′. This is 4° 15′ more than what are given by Marinus, whom in this particular Ptolemy strictly follows.

Pliny quotes from Agrippa a computation of the length of the Mediterranean, which makes it 3440 Roman miles; but in quoting it he adds a suspicion that there is an error in the numbers. When converted into degrees of longitude, the result of this computation gives 58° 20′. As, however, the length given by Strabo amounted, as we have seen, to 66° 15′, Ptolemy seems to have chosen a middle path between these two erroneous computations, and to have adopted 62° for the difference of longitude in question. But there is another ancient computation quoted also by Pliny from Polybius, according to which the length of the Mediterranean is stated to be 2440 Roman miles. Had Ptolemy followed this estimate, he would have obtained for a result 41° 4′, which is not far from the truth.

Thus we see that the circumstances under which Ptolemy wrote rendered it impossible for him to avoid mistakes, and that he might be misled even when more accurate results were within his reach.

The great obstacle with which the ancients had to contend was the finding of the longitude with accuracy, a problem for the solution of which it was long before there was discovered any method sufficiently exact. This accounts for the erroneous longitudes of Ptolemy, and more especially for the length of time, even many centuries, during which the remarkable error with regard to the length of the Mediterranean remained undiscovered and uncorrected.

We have now traced the history of geography from the earliest period of which we have any information, to the time when it assumes a scientific character. We shall conclude our account of ancient geography by shortly noticing the principal geographers of antiquity, some of whom have not yet been mentioned, while others have only been quoted in tracing the rise and progress of the science.

The intimate connection between geography and the sciences of geometry and astronomy, rendered the former an object of attention to many who anciently cultivated the latter. We have already mentioned Anaximander and Anaximenes, of the school of Miletus. Democritus, Eudoxus of Cnidus, and Parmenides, are also reported to have improved geography; and to the last is attributed the division of the earth into zones. These were followed by Eratosthenes, who lived about two hundred and forty years before the Christian era; by Hipparchus about eighty years afterwards; by Polybius, Geminus, and Possidonius. Eratosthenes wrote three books on geography, some passages of which Strabo criticises, though he frequently defends him against Hipparchus, who appears to oppose his opinions with some degree of affectation. Polybius also wrote on geography; as did likewise Geminus and Possidonius, who are frequently quoted by Strabo. Polybius, according to Geminus, argued with considerable acuteness for the possibility of the torrid zone being inhabited; and he even adduced plausible arguments to prove that the countries under the equator enjoy a more temperate climate than the countries do that are situated near the tropics.

We must not here omit a geographer and geometer who lived about the time of Alexander the Great. This was Dicearchus of Messina, a disciple of Theophrastus, who wrote a description of Greece in iambic verses, of which some fragments yet remain. But what chiefly renders him remarkable is, that he measured geometrically several mountains, to which an excessive height had been before assigned.

With Dicearchus we may notice another geometer, Xenagoras, a disciple of Aristotle, mentioned by Plutarch in his life of Paulus Æmilius, who occupied himself in the measurement of mountains. He found the height of Mount Olympus to be fifteen stadia.

In some of the latter periods which preceded the Christian era there were several writers on geography, as Artemidorus of Ephesus, who wrote a geographical work of eleven books, of which nothing remains; Scymnus of Chio, author of a description of the earth in iambic verses, which remain in a very mutilated state; Isidorus of Charax, who gave a description of the Parthian empire; and Scylax of Caryades, author of a voyage round the Mediterranean, which is still extant.

The works of all these geographers are, however, but small in comparison with the Geography of Strabo; a work in seventeen books, which has come down to us entire. This is one of the most valuable works of antiquity, both from the spirit of discussion which runs through it, and the number of curious particulars which the author has collected from different geographers and navigators who preceded him, and of whose works nothing remains except these extracts. Strabo lived in the reigns of Augustus and Tiberius, and was nearly contemporary with Pomponius Mela. This latter geographer wrote a work *De Situ*

Orbis, which, though little more than a bare summary, is valuable as it gives us a sketch of what was known in his time respecting the state of the habitable globe. Besides Mela, Rome produced in the most flourishing era of its literature another eminent geographer, Pliny. He devoted two books of his extensive work on natural history to a system of geography. His intimate connection with the imperial family, and with many of the most eminent commanders of the time, appears to have given him access to all the military measurements, as well as to the general survey of the Roman empire. Thus furnished with a greater store of authentic materials than any former writer, he has introduced a great number of itinerary details, which are for the most part accurate and valuable. Julius Solenus has also treated of geography in his *Polyhistor*, a compilation sufficiently valuable from the number of curious particulars which are there collected. Marinus of Tyre was another geographer who appears to have been distinguished, though his works have perished. Even under the Roman empire Tyre continued to be the seat of an extensive commerce; indeed the commercial relations of her citizens appear to have extended over a wider portion of the earth's surface than ever. The enlarged materials furnished by the lengthened journeys of his countrymen, which brought them even to the confines of China, Marinus collected, and sought to apply to them the astronomical principles of Hipparchus, so that he might give to geography a new and more accurate form. Ptolemy, whom Marinus preceded by a short time, employs a great part of his first book in discussing the means employed by the Tyrian geographer for fixing the relative position of places; and from the references and extracts it appears that the system of Marinus partook largely of the imperfections of a first effort.

The enlarged and scientific views of Ptolemy we have already considered. Some time after Ptolemy lived Dionysius, commonly called the *Periegetic*, from the title of a work in verse composed by him, namely, his *Periegesis*, or Survey of the World. This work was translated into Latin verse by Priscianus, and afterwards by Avienus. There is, besides, a description by Avienus, of the maritime coasts, in iambic verses, of which there remain about seven hundred.

The difficulty of procuring the small and scattered pieces of most of these authors, with those of a few others not here enumerated, induced the learned Hudson to collect them into one work, consisting of four volumes octavo, which were published in the years 1698, 1702, 1712, under the title of *Geographiæ veteris Scriptores Græci minores.* The originals are accompanied with Latin translations, and notes and dissertations on each by Dodwell. This is a very valuable collection.

We now proceed to consider the progress of geography during the middles ages. From the days of Ptolemy until the revival of letters in Europe, little was done for its solid improvement. The calamities that ere long overwhelmed the Roman empire, were followed by a general intellectual darkness which settled down on the world and extinguished even the imperfect knowledge possessed by the ancient geographers. While barbarous nations poured in from several quarters, art and science ceased to be cultivated. The union by which the Roman power had bound together mankind being now dissolved, Europe was divided into small and independent, and, for the most part, hostile communities, which had but vague conceptions respecting the situation of each other, while no intercourse subsisted between their members. With regard to remote regions all knowledge was lost; their situations, their commodities, and almost their names, were unknown.

Amidst this ignorance there were but few channels open through which knowledge could be obtained. One circumstance, however, prevented commercial intercourse with foreign nations from being altogether suspended. The opulence and luxury of imperial Rome had long given life and energy to commercial enterprise: that stimulus was now withdrawn; but Constantinople still remained, the last refuge of ancient arts, and taste, and elegance, when the rest of Europe was overspread with barbarism. Fortunately that city had escaped the destructive rage of the fierce invaders; and there, under the cherishing influence of a demand for foreign productions and luxuries, commerce continued to flourish. Alexandria continued to be the emporium whence were imported the commodities of the East Indies, until Egypt, falling under the power of the Arabians, ceased to be a province of the Roman empire. After this event the industry of the Greeks succeeded in discovering a new channel by which Constantinople might still be supplied with the productions of India. These were first conveyed up the Indus as far as that river is navigable, thence by land-carriage they were brought to the Oxus, and were carried down that river to the Caspian Sea. Entering there the Volga, they were conveyed up it, and thence were again transported by land until they reached the Tanais, down which they were conveyed to the Euxine Sea, where vessels from Constantinople awaited their arrival. By this circuitous route was a channel of intercourse kept open with the most distant countries of the East; and an extensive knowledge of remote regions was still preserved in the capital of the Greek empire, while the rest of Europe was sunk in the grossest ignorance.

The missions sent for the conversion of the northern pagans to Christianity served somewhat to illustrate the geography of Europe; though there is sufficient proof that the monks employed were, in many instances, themselves grossly ignorant, some not even knowing the capital of their own country, or the cities nearest to their own. Something was also done by the great sovereigns of Europe towards dispelling the prevailing ignorance of the age on matters connected with geography. Nor did the piratical exploits of the Danes and Norwegians under their great sea-kings fail to make them acquainted with the seas and maritime coasts where they carried on their devastations. But it was in the East that a gleam of light and knowledge began now to appear, which was the harbinger of the noon-day splendour of science that was destined to succeed the darkness of ignorance which had so long oppressed the human mind. Under the influence of a fanaticism which prompted them to own no law but the Koran and the sword, the followers of Mohammed had rushed from the heart of Arabia, and had carried their conquests over half the world. At length, however, under a race of humane and polished princes, having contracted a relish for the sciences of the people whose empire they had contributed to overturn, they stood for some time distinguished as the most learned of nations. They translated into their own language the books of several of the Greek philosophers. The valuable work of Ptolemy was one of the first; and hence the study of geography became an early object of their attention. But the advancement which the science made in their hands towards precision was slow; for they copied and retailed all Ptolemy's principal errors. Still, in all the countries that were under Mohammedan dominion numerous observations were made, which, though not always strictly correct, were entitled to be considered as a step beyond the calculations made merely from the itineraries by the Alexandrian geographers. In the beginning of the ninth century, under their caliph Almamon, who may rank among the most distinguished patrons of science that ever filled a throne, they measured a degree of latitude on the plains of Sinjar, or Shinar, near Babylon, with a view to determine the circumference of the earth. The tables of Abulfeda and Ulug Beg, and of Nazir Eddin, edited by Græevius, and republished by Hudson, furnish materials that are still of use in the construction of the maps of the interior of Asia.

The progress and success of the Moslem arms removed the obscurity in which many countries had until then been concealed, as well as the barbarism in which they had been sunk. And even beyond the limits of the Mahommedan world they pushed their researches, by sending missions both to the east and to the west, which they explored to their remotest limits. At that time Europe remained ignorant of the improvements made by the Arabians, though she was destined in subsequent ages to perfect their discoveries.

At length the long period of barbarism which accompanied and followed the fall of the Roman empire, during which the traces of whatever had embellished society, or contributed to the comfort and convenience of life, were almost entirely effaced, drew to a close. Industry began again to shed its blessings on mankind, and Italy was the country where its benign influences were first perceptible. Having from the operation of various causes again obtained liberty and independence, the Italians soon began to feel the impulse of those passions which serve most powerfully to arouse men to activity and enterprise. The reviving demand for the comforts and luxuries of life led to the revival of foreign commerce. The valuable commodities of the East were at first obtained at Constantinople. But the exorbitant price demanded at that mart, in consequence of the circuitous route by which they were conveyed thither, induced the Italians to resort to other ports, as Aleppo and Tripoli, on the Syrian coast, and at length to Egypt itself. After the Soldans had revived the commerce with India in its ancient channel by the Arabian Gulf, Venice, Genoa, Pisa, rose from inconsiderable towns to wealthy and populous cities. Their trade extended to all the ports in the Mediterranean, and even beyond the straits to the towns on the coasts of Spain, France, the Low Countries, and England; and from these points they diffused through Europe a taste for the luxuries and enjoyments of civilized life, which they at the same time furnished the means of gratifying.

It was not long ere an event occurred, the most extraordinary perhaps in the history of human society, which gave a new impulse to the European mind, and forcibly directed its view eastward to the regions of Asia. Under the influence of a high-wrought enthusiasm, the martial spirit of the Europeans was aroused, and vast armies, composed of all the nations of Christendom, marched towards Asia on the wild enterprise of delivering the Holy Land from the dominion of Infidels. The crusades, however blind the zeal from which they took their rise, had a very favourable influence on the intellectual state of Europe, and prepared it for receiving the light of science which was soon to dawn upon it. Interesting regions, known hitherto only by the scanty reports of ignorant and credulous pilgrims, were now made the object of attention and research. Not only was the way opened for the European nations acquiring a correct knowledge of the Holy Land, with the kingdoms of Jerusalem and Edessa, founded by the victorious crusaders; but the extensive regions over which the Saracens and the Turks had extended their empire began to be explored. Search was now made in the writings of the ancient geographers; nor is it improbable that some light was derived even from the Arabian writers. Religious zeal, the hope of gain, combined with motives of mere curiosity, induced several persons to travel by land into remote regions of the East, far beyond the countries to which the operations of the crusaders extended. Prompted by superstitious veneration for the law of Moses, and by a desire of visiting his countrymen in the East, whom he hoped to find possessed of wealth and power, Benjamin, a Jew of Tudela, in the kingdom of Navarre, set out from Spain in the year 1160, and travelling by land to Constantinople, proceeded through the countries to the north of the Euxine and Caspian Seas. He then journeyed towards the south, and traversed various provinces of the further India, until, having reached the Indian Ocean, he embarked and visited several of its islands; and at length, after thirteen years, returned by the way of Egypt to Europe. In his progress he had acquired much information respecting a large portion of the globe, until then altogether unknown to Europeans.

Various missions were sent by the pope and by Christian princes, for purposes which led them to traverse the remote provinces of Asia. Father John de Plano Carpini, at the head of a mission of Franciscan monks, and Father Ascolino, at the head of another mission of Dominicans, were in the year 1246 sent by Innocent IV. to enjoin Kayuk Khan, the grandson of Zengis, who was then at the head of the Tartar empire, to embrace Christianity, and to cease from desolating the world by his arms. In fulfilling the commands laid upon them by the head of the Christian church, the mendicants had an opportunity of visiting a great part of Asia. Carpini, having taken his route through Poland and Russia, travelled through the northern provinces as far as the extremities of Thibet; whilst Ascolino, who appears to have landed somewhere in Syria, advanced through the southern provinces into the interior parts of Persia.

Father William de Rubruquis, a Franciscan monk, having been sent in the year 1253 on a mission by St Louis of France, in search of an imaginary personage, a powerful khan of the Tartars, who was reported to have embraced the Christian faith, made a circuit through the interior parts of Asia more extensive than that of any European who had hitherto explored them. He had the merit of being the first modern traveller that gave a true account of the Caspian, which had been correctly described by the early Greeks as an inland separate sea; but a notion afterwards prevailed that it was connected with the Northern Ocean. Rubruquis ascertained that it had no connection with the ocean or any other sea. The account of his journey was so little read, however, that the old error was repeated in books of geography long after his time.

While the republics of Italy, and, above all, the state of Venice, were engaged in distributing the jewels, the spices, and the fine cloths of India over the western world, it was impossible that motives of curiosity, as well as a desire of commercial advantage, should not be awakened to such a degree as to impel some to brave all the obstacles and dangers to be encountered in visiting those remote countries where these precious and profitable commodities were produced. A considerable number of persons accordingly are recorded as having penetrated a greater or less depth into the interior of Asia. But the fame of all the other old travellers is eclipsed by that of Marco Polo, who has always ranked among the greatest discoverers of any age. This extraordinary man was a noble Venetian, whose family, according to the custom of his country, engaged in extensive commerce. Nicolo Polo, and Maffeo Polo, the father and uncle of Marco, were merchants, who, in partnership, traded chiefly with the East; and in pursuit of their mercantile speculations had already visited Tartary. The recital of their travels on their return fired the youthful imagination of Marco, then between seventeen and eighteen years old. Having, when in the East, gained the confidence of Kubali Khan, the great conqueror of China, at whose court they had resided for a long time, they were sent back by him to Italy, accompanied by an officer of his court, that they might repair to Rome as his ambassadors to the pope, of whom, and the potentates of the western world, they had given him an ample account. After many delays they were now, about the year 1265, to set out on their return to the court of Kublai, bearing the papal letters and benediction; and it was resolved that young Marco should accompany them. After a journey that occupied no less than three and a half years, and in the progress of which they passed through the chief cities in the more cultivated parts of Asia, they reached Yen-king, near the spot where Pekin now stands, where they were honourably and graciously received by the grand khan. Struck with the appearance of young Marco, the khan condescended to take him under his protection, and caused him immediately to be enrolled among his attendants of honour. By prudence and fidelity Marco gained so high a place in the esteem and confidence of his protector, that for seventeen years, during which he remained in his service, he was employed in confidential missions to every part of the empire and its dependencies. He made more than one voyage on the Indian Ocean, and traded with many of the islands. Besides what he learned from his own observation, he collected from others many things concerning countries which he did not visit. Considering the very favourable circumstances in which he was placed for geographical research, as well as his passion for travelling, which seems to have increased with his opportunities of gratifying it, it is not surprising that, after the long period of his wanderings in Asia, he should have returned to Europe possessed of the knowledge of many particulars, until his time unknown, respecting the eastern parts of the world. Marco, being afterwards made a prisoner by the Genoese, was induced, with a view to beguile the tediousness of his confinement, to dictate a narrative of his travels. His information was so far in advance of the age, that his veracity was exposed to the most injurious suspicions. But, if we make allowance for some tincture of credulity, characteristic of the times in which he lived, his narrative is supported in all its essential points by modern information.

While great accessions were thus made to the stock of knowledge possessed by the nations of Europe respecting the habitable globe, their ideas were at the same time gradually enlarged; and an adventurous spirit was generated, which prepared them for attempting further discoveries. Still their efforts were limited by certain bounds, in consequence of the imperfect state of navigation. Whatever conceptions a daring mind might venture to form respecting the existence of unknown regions, separated from the known continents by the mighty expanse of the Atlantic Ocean, mankind had not yet so obtained the dominion of the sea as to be able to bring such conceptions to the test of experiment. It was not until the fortunate discovery of the polarity of the magnetic needle, and the consequent construction of the mariner's compass, that man was enabled to visit every part of the globe which he inhabits. This important discovery was made by Flavio Gioia, a citizen of Amalfi, a town of considerable trade in the kingdom of Naples, about the year 1302. Encouraged by the possession of this sure guide, by which at all times and in all places he could with certainty steer his course, the navigator gradually abandoned the timid and slow method of sailing along the shore, and boldly committed his bark to the open sea. At the commencement of the fifteenth century, however, navigation appears to have advanced very little beyond the state which it had reached before the downfall of the Roman empire. But it was now destined to make rapid progress. The growing spirit of enterprise, combined with the increasing light of science, had prepared the states of Europe for entering upon that great career of discovery, of which the details constitute the materials for the history of modern geography.

Portugal took the lead in this new and brilliant path. Her first attempt was to discover the unknown countries situated along the western coast of Africa. Notwithstanding the vicinity of that great continent, and the strong inducement afforded, in the fertility of the countries already known in it, to its further exploration, Cape Non had hitherto limited the researches of the Portuguese, and had been regarded as an impassable barrier. In the year 1412, however, ships sent out for discovery doubled this formidable promontory, and reached Cape Bojador, a hundred and sixty miles to the southward, which became in its turn the boundary of Portuguese navigation; and it continued to be so for upwards of twenty years. Under the coasting system, which still continued to be practised, it was not likely that the obstacles presented by its rocky cliffs, which stretch a considerable way into the Atlantic, would soon have been overcome. But a sudden squall of wind having driven out to sea the vessel next dispatched, this event fortunately led to the discovery of the small island Porto Santo; whence in a little time Madeira was discovered, being first mistaken for a small black cloud in the horizon; and at length, when the Portuguese by their voyages thither had gradually become accustomed to a bolder navigation, Cape Bojador was doubled. Thus, by repeated efforts, the Portuguese navigators gradually approached the northern boundary of the torrid zone. Here their progress was for some time arrested, not by any physical difficulties, but in consequence of the influence which the opinion of the ancient mathematicians and geographers, whom they had hitherto followed as their guides, had upon their minds, by leading them to believe that excessive heat rendered the middle regions of the earth uninhabitable. Experience, however, at length enabled them to triumph over ignorance and prejudice. A powerful fleet, fitted out in 1484, after discovering the kingdoms of Benin and Congo, advanced above 1500 miles beyond the equator. Their intercourse with the natives enabled them to obtain information concerning those parts of the country which they had not visited. Not only had they detected the error of the ancients in reference to the torrid zone, but they found also that the direction of the coast was very different from what the description given by Ptolemy had led them to expect. They saw reason to conclude that the continent gradually became narrower as they proceeded southward; so that there was room to believe that the ancient accounts respecting the circumnavigation of Africa were really founded in truth. New and more extensive prospects were thus opened to them; and the finding of a passage to India by sailing round the southern extremity of Africa became a favourite project. In the year 1488 the lofty promontory which terminates that continent was descried by Bartholomew Diaz; but it was not until about ten years afterwards that it was doubled, and the coast of Malabar reached, by Vasco de Gama.

Meanwhile the Cape de Verd Islands, which are said to have been known to the ancients, but afterwards lost sight of, had been discovered in 1446; and soon after the Azores Isles. When we consider the distances at which these two groups of islands lie from the land, the former being upwards of 300 miles from the coast of Africa, and the latter distant 900 miles from any continent, it may be concluded that the Portuguese when they entered so boldly into the open seas, had made no inconsiderable progress in the art of navigation.

But brilliant as is the lustre which these discoveries shed around the Portuguese name, their glory would have been still more dazzling had they seconded the profound views of Christopher Columbus, which led him to the discovery of the New World. That illustrious man and skilful navigator, by revolving in his mind the principles on which the Portuguese had founded their schemes of discovery and carried them into execution, was led to conceive that he could improve on their plan, and accomplish discoveries which they had hitherto attempted in vain. From the time that they had doubled Cape Verd, the great object at which the Portuguese aimed was to find a passage by sea to the East Indies. The direction in which their efforts were made implied necessarily a long and hazardous voyage, should they even be successful in accomplishing their design. But as the Atlantic Ocean stretched westward to an unknown distance, was it not possible that it might reach the shores of those very countries to which it was thought so desirable to find a naval route? This supposition was perfectly consistent with the known globular figure of the earth; and it was evident, on the same principle, that the farther India stretched to the east, the nearer it must approach to the western shores of Europe and Africa. Such was the idea suggested to the mind of Columbus, by the knowledge which he possessed of navigation and geography, both in theory and practice. While he found his views confirmed by a careful comparison of the observations of modern pilots with the hints and conjectures of ancient authors, he became thoroughly convinced that the navigator who should have the boldness to cross the Atlantic Ocean would have his toils rewarded by the most important discoveries.

These ideas had presented themselves to the mind of Columbus as early as the year 1474; but it was not until the year 1492, after several years of fruitless solicitation, and of discouragements and disappointments of the most vexatious kind, that he obtained the patronage of Ferdinand and Isabella, who then governed the united kingdoms of Castile and Arragon, and was by them put in possession of the means of carrying his schemes of discovery into execution. With no more suitable an armament for his great enterprise than three small vessels, having ninety men, mostly sailors, on board, and victualled for twelve months, he sailed from the port of Palos in Andalusia on the 3d day of August, and steered for the Canaries. Taking then his departure from Gomera, one of the most westerly of these islands, he stretched into unknown seas; and holding his course due west, reached Guanahani, one of the Bahama Islands, on the 12th day of October. After employing some time in making further discoveries, he returned to Spain to announce the success of his undertaking, the fame of which soon spread over Europe, and excited general attention. It was no easy matter to determine what relation the newly-discovered countries bore to the regions formerly known. Columbus's own views on the subject were in strict conformity with the idea which had taken so firm a hold of his mind, namely, that India might be reached by sailing towards the west. He imagined that the islands he had visited were some of those which were said to lie contiguous to the remote shores of Asia. In this opinion he was confirmed by the coincidence which he thought he could trace between certain names given to places by the natives and the appellations known to belong to countries situated in India. He thought he could recognise, in the answer given to his inquiries after the situation of the mines which yielded gold, the name *Cipango*, by which Marco Polo and other travellers in the East designated the island Japan. Ignorant of their language, and unaccustomed to their pronunciation, he even supposed that they spoke of the great khan; and hence concluded that the kingdom of Cathay or China, described by Marco Polo, was not far off. The same erroneous opinion was still further riveted in his mind, by what he supposed an identity between the animal and vegetable productions of the East Indies and those of the countries which he had discovered.

His second voyage led to the discovery of several more of the group of islands now called the West Indies, a name given them in conformity with the original notions of the discoverer. It was on his third voyage that he discovered the vast continent of America. Having unexpectedly found the island of Trinidad, with the neighbouring land, he encountered, before he was aware of danger, the adverse currents and tumultuous waves occasioned by the resistance which the waters of the Orinoco oppose to the tides in the ocean. His attention was thus forcibly called to the immense body of water which is here poured into the Atlantic. This he was convinced was vastly too great to be supplied by any island; and hence he concluded that he had now reached the continent which he had sought through so many dangers.[1]

The tenacity with which an ingenious and enterprising mind adheres to a scheme which it has once proposed to itself as an object of pursuit, was strikingly evinced by Columbus, whose thoughts still dwelt with eagerness on his original and favourite plan of opening a new passage to India. It was not enough that he had astonished mankind by finding a new continent; he conceived the idea that beyond it there might lie a sea extending to the coasts of Asia, and that by diligent search some strait might be found which would conduct him into this sea, or some narrow neck of land, by crossing which it might be reached. To determine this important point, though hitherto his services had met with the most unworthy returns, though years crept upon him, though worn out by fatigue and broken with infirmities, he still undertook with alacrity another voyage. By a lucky conjecture he directed his efforts towards the east of the gulf of Darien; but he searched in vain for a strait; and though he frequently went on shore and advanced into the country, he never penetrated so far as to enable him to descry the great Southern Ocean.

After the first steps had been taken, the progress of discovery over the globe was astonishingly rapid. No expense or danger deterred even private adventurers from fitting out fleets, crossing oceans, and encountering the rage of savage nations in the most distant parts of the earth. Before Columbus had reached the continent at the mouth of the Orinoco, Newfoundland had been discovered by Cabot, a Venetian by descent, but sailing under the auspices of England. He had also coasted along the present territory of the United States, perhaps as far as Virginia. In the next two or three years, the Cortereals, a daring family of Portuguese navigators, began the long and unavailing search of a passage round the northern extremity of America. They sailed along the coast of Labrador, and entered the spacious inlet of Hudson's Bay. Two of them unfortunately perished in this enterprise. In the year 1501 Alvarez Cabral, a Portuguese navigator, destined for India, having stood out to sea in order to avoid the variable breezes and frequent calms which he was sure to meet with on the African coast, to his surprise, came upon the shores of an unknown country, the coast of Brazil, which he claimed for Portugal. Amerigo Vespucci, a Florentine gentleman, who had already sailed along a great part of Terra Firma and Guyana, now made two extensive voyages along the Brazilian coast. Soon after his return he drew up and transmitted to one of his countrymen an account of his adventures and discoveries, in which he insinuated that to him belonged the honour of having first discovered the continent in the New World. His performance, which was the first description published of the newly-discovered countries, circulated rapidly, was read with admiration, and became the means of procuring for its author the high honour of giving his name to the whole continent. Not many years elapsed before the conjecture of Columbus respecting the existence of an ocean beyond the continent which he had discovered was found to be true; and his favourite project of opening a passage to India by steering westward was actually accomplished. By crossing the narrow isthmus of Panama, Nuñez Balboa reached the Pacific Ocean in the year 1513; and in 1521 Magellan discovered and sailed through the famous straits which bear his name. After twenty days occupied in navigating this dangerous channel, he beheld spread out before him the boundless expanse of the great Southern Ocean. Directing his course to the N.W., he continued his voyage for nearly four months without discovering land. From want of provisions and from sickness, he and his crew suffered dreadful distress. But when about to sink under their sufferings, they fell in with the Ladrone Islands, where they found refreshments in abundance. From these isles he proceeded on his voyage, and was not long of discovering the Philippines. Here, in an unfortunate quarrel with the natives, he was slain, with several of his principal officers. But his surviving companions, pursuing their voyage, and returning to Europe by the Cape of Good Hope, solved the great problem of the circumnavigation of the earth.

---

[1] The American continent in its northern portions had been discovered in or before the eleventh century. Towards the close of the ninth century a Norwegian pirate, while attempting to reach the Faroe Islands, which had already been visited by the Irish, was driven by storms to the coast of Iceland. This led to the first settlement of the Norwegians in Iceland in 875. From that time the Faroe Islands and Iceland may be regarded as intermediate stations and starting points for attempts to reach the northern shores of America. Greenland was early seen; but it was not until 983 that it was peopled from Iceland. Colonization was carried through Greenland in a south-western direction to the new continent, and for some length of time an inconsiderable intercourse was maintained with the newly colonized countries. But a strong line of separation must be drawn between this early discovery of some parts of the high northern latitudes of America, and the discovery of its tropical regions by Columbus in the close of the fifteenth century. In consequence of the uncivilized condition of the people by whom the former discovery was made, as well as the nature of the countries to which it was limited, it produced no important or permanent results in relation either to commerce or science; the latter, on the other hand, has been attended with events of the utmost importance to mankind, as it has proved the opening of a new source of wealth, glory, and knowledge. The discovery of the new continent in the west, like the original discovery of its northern regions, may be said to be accidental, inasmuch as the object which Columbus had in view was to find a western passage to India. But the expedition under Columbus possessed this distinguishing feature, that it manifested the perfect character of being the following out of a plan sketched in accordance with the principles of science, and intelligently conducted to a successful issue.

After the discovery of the Pacific Ocean by Balboa, the investigation of the western coasts of America went speedily forward. Expeditions were soon sent out both northward and southward; so that nearly a full view was obtained of the immense range of coast which the American continent presents to the Pacific Ocean, and at the same time of its great interior breadth.

On the other hand, discovery in the Eastern World was no less rapid. Within twenty years from the time that Gama reached India by the way of the Cape of Good Hope, all the coasts of Hindustan, those of Eastern Africa, of Arabia, and Persia, had been explored. Navigators had penetrated to Malacca and the Spice Islands. They had learned the existence of Siam and Pegu; and it was only the characteristic jealousy of the rulers of the Celestial Empire that prevented them from entering the ports of China.

The scientific geographer had now abundance of materials to arrange and digest into one systematic whole. He was now called upon to give such a delineation of the earth's surface as should connect together the ranges of eastern and western discovery, and should exhibit the true outline and relative positions of countries, as these had been demonstrated by the astronomer and navigator. The ancient system of geography, to which the Arabs seem closely to have adhered, was founded on the idea of the whole earth being surrounded by an ocean as by a great zone. This the Arabians characterized as the "Sea of Darkness," an appellation most usually given to the Atlantic; while the northern sea of Europe and Asia, as inspiring still more gloomy and mysterious ideas, was styled the "Sea of Pitchy Darkness." Such notions could not now keep possession of the human mind, though it was only by degrees that mankind could be expected to be enlightened by doctrines which were not only new, but seemed likewise to be contradicted by the evidence of sense. The fundamental principles of a systematic arrangement had, as we have already seen, been known from the time of Hipparchus, and had been reduced to practice by Ptolemy. But the want of astronomical observations, or even of accurate surveys, which navigators seldom furnished, and for which science had not indeed yet provided suitable instruments, placed it still beyond the resources of modern geography to give anything like a just representation of the two hemispheres. The Venetian geographers were the first who attempted a systematic arrangement of the immense regions recently discovered, adjusting them to each other, and to the mass of information previously possessed. But a series of Venetian maps, preserved in the king's library, show how much their skill was counteracted by the difficulties with which they had to contend. Instead of exhibiting the vast ocean which separates the east coast of Asia from the west coast of America, the two continents are represented either as meeting, or as separated only by a narrow strait. The voyage of Magellan across the Southern Ocean had not shown with sufficient distinctness the presentation of the opposite coasts, to enable the geographers of the time to avoid this error. When maps of different dates are compared, we find, as we descend towards modern times, a gradual progress towards accuracy in the representations given of the earth's surface. This is what might be expected; for all maps should be considered as unfinished works, in which there will always be something to be corrected, or something new to be inserted.

At the period of the revival of letters in Europe, the latitudes and longitudes as given by Ptolemy were universally received with implicit confidence. When checked, however, by actual observation, they were found to differ materially from the truth. The latitudes in many instances were found very erroneous; that of Byzantium, for example, exceeded the truth by two degrees. As nearly the same excess was found to exist in some other cases, many geographers, unwilling to renounce the authority of Ptolemy, concluded that this difference had arisen from a change having taken place in the position of the earth's axis, in consequence of which the latitudes of all the places in Europe were increased. The progress of observation showed that this opinion was untenable, and that before geography could rest on a sure basis, a general revision of ancient graduation was indispenably necessary. The only observations employed by the ancients for determining longitudes were those of the eclipses of the moon; but it was found that the results derived from this source could not be depended on. In the year 1610, Galileo, having discovered three of Jupiter's satellites, pointed out the use which might be made of their eclipses for finding longitudes. But this method, which gives the greatest degree of accuracy, was turned to little account, until 1668, when Cassini published his tables of the revolutions and eclipses of these satellites. Three years afterwards, by means of simultaneous observations made by him and Picard at Paris, and by Tycho Brahe at Copenhagen, the difference of longitude of these two important points, which had been long a matter of dispute, was finally determined. Since that time, other accurate methods of finding the longitude have been discovered; and the instruments employed in observation have been brought to a high degree of perfection. The refinements and improvements of modern science have been brought to bear upon the great problem of determining the figure of the earth, which, though nearly, is not exactly spherical. (See Figure of the Earth.) The labours of scientific men to obtain accurate results on this subject, have contributed much to the improvement of geography. The expeditions sent out under Maupertuis to the arctic circle, and under Condamine to the equator, afforded an opportunity of making various observations of latitude and longitude in regions of which no delineation resting upon proper data had hitherto been given. Within the last fifty years, trigonometrical surveys of France and England have been executed, which have nearly completed the delineation of these countries.

Much advantage has accrued to geographical science, in point of accuracy and precision, from the application in modern times of a sound and judicious criticism to the immense mass of materials which had been accumulating for ages. The labours of M. d'Anville, in the eighteenth century, were employed with great success in this department. He undertook the revision of the whole system on which the delineation of the world, and of the countries into which it is divided, had hitherto been made; and by unhesitatingly rejecting every particular that did not rest on positive authority, he removed many false or uncertain features, and clearly distinguished the known from the unknown parts of the globe. Major Rennell has skilfully arranged and illustrated the important materials collected respecting India. Various authors have in modern times cultivated another interesting field of inquiry, the comparison between ancient and modern geography, and the tracing of the rise and progress of early discovery. These researches were diligently pursued by Vossius, Bochart, and other learned men of the seventeenth century, and with still more success by Rennell, Vincent, and Mannert, who appear to have pushed them as far as they admit, though much darkness still rests on some parts of the inquiry. Gosselin, notwithstanding that he has applied to the subject a great extent of investigation, as well as much skill and force of criticism, has failed, on account of the peculiar views in which he indulged, to make any solid addition to the science.

The discoveries made by the Spaniards and Portuguese had greatly increased the stock of geographical information. Still much remained to be done. The desire of finding a short and convenient route to India continued to supply a stimulus to exertion in the way of discovery. The English and Dutch made extraordinary efforts, and encountered fearful dangers and disasters, with the expectation of effecting a passage by the north-east, along the northern shores of Asia. A coast beset with the ices of the Polar Seas presented, however, obstacles too formidable to be overcome; though recent researches show that no barrier of land intervenes. But there was still another quarter where an attempt might be made; and to this point the commercial nations of Europe failed not to direct their efforts. The jealousy of Spain long prevented the other European states from visiting the north-western coast of America, so that they remained ignorant of the vast breadth to which the continent spreads out as it advances towards the north. They adopted, indeed, the opinion that, like the southern extremity, the northern terminated in a point or cape. This left room to hope for a north-western passage into the Pacific Ocean, by sailing round the imaginary cape. The English took the most decided lead in the exploratory voyages to which these views gave rise. In the reign of Queen Elizabeth, Frobisher and Davis were sent out on three successive voyages, which led to the discovery of the entrance into Hudson's Bay by the former navigator, and of the entrance into Baffin's Bay by the latter. These two capacious basins were afterwards discovered by the intrepid navigators whose names they bear. In sailing round the great sea which he had discovered, Baffin mistook the great opening into Lancaster Sound for a mere gulf; a misapprehension which checked for a time any further attempts in that quarter, as navigators were led to expect success only through the channel of Hudson's Bay. In 1631, Fox explored a part of that great opening on the north of Hudson's Bay, called Sir Thomas Roe's Welcome, which seemed now to hold out almost the only hope of accomplishing the object sought. The assertion of Middleton, an officer in the service of the Hudson's Bay Company, that he had discovered the head of the Welcome to be completely closed, and the circumstance of two other navigators, who were sent out the following year, failing to effect anything, produced an impression on the public mind that the passage so long sought had no existence.

The discoveries of Cook in the North Pacific Ocean, where he found the American coast stretching away in a north-westerly direction, joined to the circumstance that, when he penetrated through the strait discovered early in the last century by Behring and Tchirikof, which separates America from Asia, the coast appeared there to extend indefinitely to the north, seemed not only to confirm the conclusion that no passage into the North Pacific Ocean was here to be expected, but also that the American continent extended northward in one unbroken mass, perhaps even to the pole. The groundlessness of these views became apparent when, in the year 1771, Mr Hearne, who had been despatched by the Hudson's Bay Company to explore the limits of the coast in this direction, sailed down the Copper-Mine River, and discovered its entrance into the sea; and again, when, in 1780, Sir Alexander Mackenzie traced also to the sea another river about twenty degrees farther to the west. Thus were there furnished strong grounds to believe that the pole was surrounded by an ocean which separated the northern coasts of Asia and America, making these two continents altogether distinct from each other; and that through this ocean lay the long-sought course which would certainly conduct the navigator who should succeed in forcing his way through the ice and storms of the polar regions, from the Atlantic into the North Pacific Ocean.

The determination of this great geographical question, so long agitated, has recently called forth the utmost efforts of the British government. In 1818 an expedition was sent out to Baffin's Bay under the command of Captain Ross, without leading to any important result, as he was led to conclude that no opening existed. Lancaster Sound had, however, forcibly attracted the attention of the late Sir Edward Parry, at that time lieutenant and second in command; and on returning with a new expedition under his immediate command, he succeeded in penetrating through Lancaster Sound, which he found gradually to widen till it opened into the Polar Sea. He found a chain of large islands to lie parallel to the American coast; and among these he continued his navigation until the accumulation of ice in the straits and channels through which he had to pass stopped his further progress. This circumstance induced him to make his next attempt through Hudson's Bay, by the channel of the Welcome, which had as yet been but imperfectly explored. Here he succeeded in reaching a point considerably beyond that at which Middleton had represented the bay as terminating. He found at length a narrow strait communicating with the Polar Sea, but so encumbered with ice as to preclude the hope of its ever affording an open passage. He was therefore again sent out to renew his efforts in the first direction, where he had already obtained partial success. But the obstacles which he had formerly been unable to overcome still continued, and prevented him from making any material addition to his former discoveries. Whilst these skilfully-conducted voyages were in progress, Sir John, then Captain Franklin, was sent out at the head of two successive expeditions by land, and, by actual survey, ascertained three-fourths of the boundary coast; his operations terminating at a point beyond the 149th degree of west longitude. On the other hand, an expedition under Captain Beechy, sent to meet Captain Franklin on his second toilsome journey, passed the Icy Cape of Cook, and penetrated nearly as far as the 156th degree of west longitude, leaving only seven degrees, or 160 miles, between the farthest point thus reached and the utmost limit reached by Captain Franklin. The results of this investigation appeared to prove that the whole of the northern coast of America extends in a line not varying much from the parallel of the 70th degree of north latitude. The problem of a passage between the Atlantic and Pacific Oceans, to the north of the American continent, has now been finally solved: but this discovery, so well fitted in itself to afford satisfaction to the British nation, which has always taken the lead in such enterprises, has been made under circumstances of a very saddening kind. In 1845 Sir John Franklin and Captain Crozier were sent out on a voyage of discovery to the Arctic Seas. No tidings having been received of this expedition, it became, after two or three years, a subject of painful anxiety and suspense. Hence various expeditions were fitted out and sent in search of the missing voyagers, to succour them if still within reach of human aid, or, if otherwise, to ascertain their fate. In the course of these praiseworthy endeavours, Captain M'Clure was appointed to command the Investigator, under Captain Collinson of the Enterprise, and proceeded with that officer to Behring Straits in the early part of 1850. When on the eve of sailing, Captain M'Clure emphatically declared that he would find Sir John Franklin and Captain Crozier, or make the north-west passage. The latter part of this pledge he has, geographically speaking, redeemed; but the impenetrable mystery which from the first enveloped the fate of these gallant commanders remains the same. Captain Collinson failed in his attempts to penetrate the pack ice that season, and so was separated from Captain M'Clure, who, notwithstanding a signal of recal from Captain Kellett of the Herald, the chief officer on that station, dashed onward with a bold determination to force a passage to the north-east—taking on himself all the responsibility of disobeying orders. Fortunately his daring has been crowned with success. He rounded Point Barrow on the 5th August 1850: continuing his course eastward along the coast, he reached Cape Parry on the 6th September, whence he steered through a channel called Prince of Wales Strait; which, running north-east, appeared a most promising course for reaching the sea south of Melville Island. Near the northern extremity of this strait, the Investigator was frozen in from the 8th of October, and remained stationary during the winter. Parties being sent out to explore, it was soon ascertained that the channel opened into Barrow's Strait; and thus was the existence of a north-west passage established. On the 14th July 1851 the Investigator was again fairly afloat, the ice having opened without any pressure. The great object now to be gained was to pass through the strait; but notwithstanding their utmost exertions, the expedition was completely arrested by strong north-east winds, driving great masses of ice to the southward. Thus baffled, Captain M'Clure resolved on running to the southward of the island, forming the western boundary of Prince of Wales Strait, which he had named Baring Island, and then to sail northward along its western side. This navigation, in which he was subjected to many delays and encountered many formidable obstacles, he accomplished, and succeeded in reaching the north side of the island on the 24th of September. Had open water existed to the east the rest of the passage might have been easily performed in this way, for Barrow's Strait lay before them, the navigation of which from their position to Lancaster Sound was known to be practicable. The hopes of this intrepid navigator were destined again to be disappointed. On the night of the above mentioned day the Investigator was frozen up, and at this point, in latitude 74° 6′ N. and longitude 117° 54′ W., they had their winter quarters in 1851, 1852, 1853. In April 1852 a party crossed the ice to Melville Island, and deposited there a document giving an account of their proceedings, and of the position of the Investigator. This document was happily discovered by the officers of Captain Kellett, who had been the last person with whom Captain M'Clure held communication when he entered the ice on the west, and was now, singularly enough, the person to rescue him at the expiration of three years on the side of Melville Island on the east. Steps were immediately taken to communicate with the party in their ice-prison, Lieutenant Pim being appointed by Captain Kellett to the service. Eventually it was found necessary that Captain M'Clure and his gallant companions should abandon their ship, however unwillingly; so that the navigation of the north-west passage has not yet been accomplished.

The discovery of a new continent greatly enlarged, as we have seen, the views of mankind respecting the constitution of the globe. But imagination, no longer limited in its range by the notion of a circumambient ocean that could not be passed, soon gave rise to the belief of a southern continent, which was supposed necessary to balance the land in the northern regions of the earth. The immense body of water that was found to occupy so large a portion of the known regions of the southern hemisphere gave ample room for supposing this unknown continent to be of vast dimensions. It was imagined that it might equal in extent as well as in wealth the American continent. Nor was it considered necessary to exclude it from the map of the world till its existence should be proved. It appears in all the early maps as an immense mass of land surrounding the south pole, and presenting to the ocean one unbroken coast. The discovery of certain great insular tracts in the South Seas, which, from ignorance of their true nature, navigators might mistake for continental promontories or portions of coast, no doubt at first gave some countenance to the belief of the existence of antarctic land. But the delusion was gradually dispelled before the light afforded by further discovery. The Portuguese, in less than twenty years after their passage of the Cape of Good Hope, pushed their researches to the most remote islands in the Indian Ocean, including Java and the Moluccas. They appear also to have observed some part of the coast of New Guinea. The Spaniards during their early and adventurous career put forth strenuous exertions to explore the Southern Ocean, and several of the groups of islands scattered over its surface were discovered by their navigators. In 1607, the Dutch having wrested from the Portuguese Java and the Spice Islands, established in them the centre of their Indian dominion. A great maritime power being thus placed so near to the northern shores of the largest portion of land on the globe that is regarded as an island, it became almost impossible that New Holland could long remain unknown. It was discovered early in the seventeenth century, and was long supposed to form a part of the great southern continent. Van Diemen, the Dutch governor of India, sent out several vessels successively to explore its coasts. Hertog, Carpenter, Nuytz, and Ulaming made very extensive observations on the northern and western shores, but found them so dreary and uninviting that no settlement was attempted. In the year 1642 Abel Jansen Tasman was commissioned to proceed on a voyage to ascertain its extent. On the 14th August he sailed from Batavia, directing his course first towards the Isle of France. He again set sail on the 3d October, and proceeding southward and eastward, beyond the limits reached by his predecessors, he discovered and doubled the southern extremity of Van Diemen's Land, to which he gave its name; but he failed to discover that it is a separate island. Pursuing afterwards his course eastward, having reached about 42°10′ S. Lat. and 170° E. Long., he found himself in view of a high and mountainous country, which he named Staaten Land, but which is now known as New Zealand. He sailed along the coast towards the north-east, and after being detained by the variableness of the weather, he resumed his voyage and returned home by the Friendly Islands, discovering many islands in his progress. He arrived at Batavia on 15th June 1643. Tasman's voyage proved that New Holland was no part of the southern continent, even if such a continent should be found to exist. Cook, who had been appointed in 1767 to conduct a voyage into the South Pacific Ocean for astronomical and geographical purposes, sailed southward in 1769 in quest of the unknown continent. Lofty mountains were seen on the 6th October, and it was supposed that the object of their search was found. But the land proved to be New Zealand. This land he circumnavigated, and found that it consisted of two large islands separated by a narrow channel. After six months employed in this manner, he directed his course westward, and reached the eastern side of New Holland early in 1770. By his extensive operations in that quarter—having run down the coast from latitude 38° to its northern extremity at Torres Strait—he left little more to be done there in the way of discovery. Passing between New Holland and New Guinea, he continued his voyage by Timor and the south coast of Java to Batavia; whence, after repairing the ship, he sailed for England, and reached the Downs on the 12th June 1771, with his crew weakened and reduced in number by the fatigue and hardships of their long voyage. By this voyage it was proved there was no such continent as that supposed to exist to the northward of 40° south latitude. But as many ingenious and well-informed men still adhered to the opinion that there did exist a southern continent, government determined to send out a second expedition under Cook, to make such an exploration of the Pacific Ocean in the higher southern latitudes as should finally and satisfactorily settle this much-agitated question. Cook was instructed to circumnavigate the globe in high latitudes, prosecuting his researches as near to the South Pole as possible, and to traverse every part of the Southern Ocean where the supposed continent could possibly lie. The expedition sailed from Plymouth 13th July 1772, and quitted the Cape of Good Hope 22d November. Pursuing his course eastward, Cook, during three years, employed the summer months in those regions (corresponding to our winter months) in navigating high latitudes towards the South Pole, and the winter months in adding to his discoveries in the South Pacific Ocean. Notwithstanding, however, that he varied his course, and traversed in every direction which he thought afforded the slightest likelihood of finding land, and actually got so far south as 71° 10′ of latitude, he was unsuccessful. Having thus scrupulously and completely accomplished the object for which he was sent out, he directed his course homeward. He had encompassed the globe in high latitudes, and was led to conclude that the Southern Pole is surrounded only by isles and firm fields of ice, so that the hypothesis of an austral continent had no foundation. He reached the Cape of Good Hope 22d March 1775, and anchored at Spithead on the 30th July, having, in the space of three years and eighteen days, sailed 20,000 leagues, mostly in unhospitable climates and unknown seas. In the course of this and his former voyage the same great navigator secured glory to his country and to himself by likewise completing the survey of the Great Pacific Ocean. Some of the interesting groups of islands scattered over its vast surface had already been made known by the previous voyages of Byron, Wallis, and Carteret. Cook fully traced the great chain of the Society Islands and the Friendly Islands. He determined also the form and relations, not only of New Zealand, but of New Caledonia and other lands and islands in that region of the globe.

The extensive island of New Holland has recently become doubly interesting from the important relations which now subsist between it and Europe. In the year 1788 the establishment of a British colony on the east coast paved the way for a more complete survey. By the different expeditions undertaken from 1795 to 1799, chiefly under the direction of Bass and Flinders, the east coast, together with Van Diemen's Land and Bass's Strait, which separates that island from New Holland, were accurately explored. In 1801 an expedition was sent out by the British government under the command of Captain Flinders, for the purpose of surveying a large portion of the coast. These surveys were prosecuted with unremitting ardour and perseverance. At the same time that Captain Flinders was carrying on his survey, the French captain Baudin was employed on the same service, and in some parts the discoveries of these navigators intermingle. Some additional observations have more recently been made; and by these various expeditions the whole coast of New Holland and Van Diemen's Land has been accurately surveyed, the position of every point has been ascertained, and every inlet and bay has been traced to its termination.

The strong presumption which the researches of Captain Cook in the Southern Ocean furnished of the non-existence of an austral continent, seemed to leave no room to expect that any further doubt would be entertained on the subject. Lieutenant C. Wilkes, commander of the expedition fitted out in 1838 by the government of the United States, for the exploration of the antarctic regions, has, however, claimed for his country and for himself the honour of at length discovering a continent within the antarctic circle. While this claim is pertinaciously adhered to, no distinct and unequivocal proof is produced that the continent alleged to have been seen by the American Expedition has a substantial existence. No continent or island was landed on; and, on the other hand, there is no doubt that the British Expedition under the command of Sir James C. Ross sailed over the very spot in south latitude 66°, and east longitude 163°–166°, where Lieutenant Wilkes supposed he saw mountainous land. This latter expedition was fitted out by the British government for scientific purposes in 1839, and arrived in Van Diemen's Land in August 1840. The French government had likewise sent an expedition into the southern seas, under the command of Captain Dumont d'Urville, about the same time. To avoid interference with the French and American discoveries, Sir James Ross determined on a more easterly meridian—that of 170° E.,—in which to endeavour to penetrate to the southward. The expedition sailed from Hobart Town on 13th November 1840, and on 27th December encountered a chain of icebergs. On the 5th January 1841 they entered the pack-ice, through which having forced their way, the ice having at the same time somewhat slackened, they found themselves on the 7th January again in a clear sea. Soon after 2 o'clock A.M. of the 11th January they discovered land, which, as they advanced southward, was found to extend continuously from the 70th to the 79th degree, with several adjacent islands. This land they called Victoria Land. It presented to their view ranges of mountains whose lofty peaks, covered with eternal snow, rose to elevations from seven to ten or even twelve thousand feet above the level of the ocean. The intervening valleys were filled with glaciers, which, descending from near the mountains' summits, projected in many places several miles into the sea, and terminated in perpendicular cliffs. The rocks breaking through in a few places their covering, afforded the only indication that land formed the nucleus of this, to appearance, enormous iceberg. On the 28th January, when they had nearly reached their highest latitude, about 78° S., they found that what appeared when first seen at a distance to be a high island, was a mountain 12,367 feet in height, emitting flames and smoke in great profusion. This volcano lies in latitude about 77½° S., and in longitude about 167° E. From the most eastern point of land at a cape not far from the foot of this mountain, an icy barrier was found to extend eastward as far as the eye could discern. This barrier was a perpendicular wall of ice from 150 to 200 feet in height, and stretched 250 miles in one unbroken line, as was found on a second visit to the same interesting locality in February 1842; nor were they able to turn its extremity, so as to reach a higher latitude. At a point where the height of the barrier diminished to about 80 feet, they perceived from the mast-heads that it gradually rose to the southward, presenting the appearance of very lofty mountains perfectly covered with snow, but with a varied and undulating surface. And hence Sir James Ross, with nearly all his companions, felt assured that the presence of land there amounts almost to a certainty. Still, Sir James is of opinion that the recent discoveries in the antarctic regions made by the French and American navigators, and by himself, do not prove the existence of a great southern continent, but rather of a chain of islands.

In tracing the history of geographical discovery, it cannot fail to be observed that while discovery by sea admits of being pursued with great advantage, on account of the rapidity of its progress and the extent of its range, it does not supersede the slower and more confined operations of the discoverer by land, which are no less necessary to make known the interior features and circumstances of the different countries.

The British dominion in India has led to much additional information respecting the interior of Asia; information which is, however, in many respects, only the revival of ancient knowledge. The great mountainous chain which forms the northern boundary of India has been traced and found in many places to tower to such heights as to exceed the Andes, long supposed to be the highest mountains in the world. The source of the Ganges, and that of the Indus, with the early courses of these great rivers, have been found to be situated quite differently from what had been supposed to be their position by modern geographers. The mountainous territories of Cabul and Cashmere, the high interior tableland of Thibet, and the vast sandy plains of Meckran, have all been more or less explored. Information of an authentic character has also been recently obtained respecting the formerly celebrated capitals, Bochara and Samarkand. But a wide field still remains for future research.

The continent of Africa, however, is the quarter of the globe which, more than any other, has baffled the efforts of those who would explore its interior. The vast sandy deserts, high mountains, and impenetrable forests which occur on its surface, joined with the unremitting wars carried on between the petty tribes, as well as the deeply-rooted antipathy of the African Mohammedans towards the Franks, have presented obstacles of the most formidable kind. The ancients, whose knowledge of the African coasts was very imperfect, except where they border on the Mediterranean and the Red Sea, were accustomed to penetrate into the inland provinces, and are said to have been acquainted with many parts of it which are now altogether unknown. At an early period of modern history, reports that Prester John, the Christian prince, who had been sought for in vain in the East, was to be found in the interior of Africa, induced the Portuguese to explore Abyssinia; but the accounts which they gave of the extent of that country were greatly exaggerated. From the western coast they despatched embassies into the interior in quest of the object of their search; and on one occasion they appear to have reached the city of Timbuctoo, and to have obtained at Benin some information concerning the great interior kingdom of Ghana. The maritime nations of south-western Europe early formed settlements on the west coast of Africa, and, for commercial purposes, were naturally prompted to seek a knowledge of the neighbouring nations. But it was not until the formation of the African association in 1788 that any well-sustained efforts were made in the prosecution of discovery in the interior. There were two objects connected with the interior of Africa which had for a long time fixed the attention and awakened the curiosity of the nations of Europe. These were the city of Timbuctoo and the great central river, the Niger. Timbuctoo has been for many centuries the grand emporium of the central trade of Africa, and hence there has prevailed throughout Europe, ever since the rise of discovery and commercial enterprise, a strong desire to visit it, and to establish with it a friendly intercourse. The discovery of the course and mouth of the Niger has now opened up to commercial speculation what it is hoped will give a ready access to Timbuctoo as well as other places of traffic. The interest with which, in a geographical point of view, however, the Niger has been regarded, has arisen from the remarkable nature of the regions through which it flows, and still more from our ignorance, combined with the various and contradictory rumours which were so long abroad, respecting its course and termination. Herodotus is the earliest author who affords any ideas applicable to this subject. He mentions an expedition into the interior of Africa, undertaken by some Nasamonian youths, who, being made prisoners, were carried to a great city inhabited by negroes, and situated on the banks of a river which flowed from west to east. This stream he conjectures to be the remote source of the Nile, but the particulars given appear to leave little doubt that it was the Niger. A similar hypothesis was adopted by Strabo, Mela, and Pliny, identifying the waters of these two great rivers. But Ptolemy, whose residence in Alexandria afforded him ample means of information, rejects altogether the idea of any communication between them. He describes the Niger as terminated on the west by Mount Mandrus (Mandingo), and as giving rise to several extensive lakes as it proceeds in its course. His statements do not, however, involve anything positive as to the direction in which it flows. The Saracens or Arabians are the next great source of information; for, in the course of the dissensions which took place among their dynasties in Northern Africa, large bodies crossed the desert and founded kingdoms on the eastern part of the shore of the Niger, of which the kingdom of Ghana was the most splendid. According to their testimony, the Niger flows from east to west, and discharges itself into the sea, by which they understood the Atlantic, or great circumambient ocean. With regard to its source, they generally regarded it as the same with that of the Egyptian Nile, identifying the two rivers in the early part of their course. Some were of opinion that the waters of the Niger did not reach the sea; so that they must have supposed them to be discharged into a lake. The system adopted by modern Europeans was derived from Leo Africanus, who retained the delineations of the Niger as flowing from east to west, and falling into the ocean; but, instead of deriving it from the Nile, supposed it to rise from a lake lying deep in the interior of Africa. Following this hypothesis, all the early European navigators, when they saw the two broad estuaries of the Senegal and Gambia, concluded that one or both gave egress to the waters of the Niger. In the beginning of the seventeenth century, the French and English, having each formed a settlement, the one on the Senegal and the other on the Gambia, were induced by the hope of gain to seek a route up these rivers to the city of Timbuctoo; and in this enterprise they proved the falsity of the opinion which had been so long held. The streams were traced so near to their source as to become little more than rivulets; whilst the explorers were still far from the great central emporium of Africa, and from the great plain through which the Niger was understood to flow. This result led the two great French geographers, Delisle and D'Anville, to construct maps in which the Niger, after the lapse of so many ages, was again represented as flowing to the eastward. Instead of a single stream pursuing a course across the whole breadth of Africa and falling into the Atlantic, D'Anville distinguished three rivers—the Senegal, flowing westward; the Niger, flowing eastward into a lake in Wangara; and another river still farther east, and flowing in the opposite direction. The data on which this scheme rests were never fully made public.

Still new doubt was thrown around this subject by the reports collected by Mr Lucas, who travelled under the auspices of the African Association, and who was assured at Tripoli, by a native merchant, that the river flowed with rapidity in a westerly direction. The time, however, at last arrived, when these conflicting opinions were to be silenced, and when new light was to be thrown on the subject, by the labours of our illustrious modern traveller, Mr Mungo Park. In his first expedition, in 1795–96, he proceeded from the west coast in the direction of the river Gambia, until at Medina he left it, and turned to the north. Having passed through the kingdoms of Bondou, Kasson, and Kaarta, he reached Sego, the capital of Bambarra, where he beheld " the long-sought majestic Niger glittering in the morning sun, as broad as the Thames at Windsor, and flowing slowly to the eastward," directing its course into the depths of the interior of Africa. This stream, he found, was called by the natives the Joliba, or Great Water. Park advanced beyond this point to another town called Silla on the same river, and acquired also some valuable information respecting the further course of the stream which was the object of his research, as well as respecting the position of Timbuctoo, which he was told was not more than 200 miles from Silla. Following upwards the course of the Joliba until he reached Bammakoo, which was stated to be about ten days' journey from its source, he returned to the Gambia by a more southerly tract. In 1805 this adventurous traveller was sent out at the public expense on his second expedition. After reaching Silla, he embarked at a place in its neighbourhood on the Joliba or Niger, with the determination of sailing down the stream until he should reach its mouth, whithersoever its course might conduct him. He is ascertained to have passed successively the cities of Jenné, Timbuctoo, Yaour or Yaouri, and to have reached Boussa, a short distance farther down, where he was killed. No part of his journal, however, after he embarked on the river, has been recovered. In the meantime, a strong and general interest being now excited in reference to African geography, information flowed in from various sources respecting the regions in the interior, as well as some parts nearer the coast. Many particulars became known concerning the countries to the east of Timbuctoo, especially the kingdom of Bornou, then the most powerful state of Central Africa. The knowledge possessed of the people of the interior was also considerably increased. These circumstances prepared the way for a more successful attempt than any hitherto made to explore the interior of Africa, when Major Denham and Lieutenant Clapperton were sent out in 1822. Setting out from Tripoli with a caravan of Arab merchants, these travellers crossed the desert, and reached the great inland sea or lake called Tchad, which is the receptacle of immense volumes of water collected from the most distant recesses of inner Africa. Major Denham examined the coasts of this lake to the east and south; while Lieutenant Clapperton directed his researches westward, through the kingdom of Bornou and the country of the Fellatahs, until he arrived at Sackatoo, situated on a stream which probably flows into the Joliba. In the course of this journey Clapperton obtained a great mass of information concerning those hitherto unvisited regions which lie eastward of Timbuctoo; but with regard to the course of the unexplored part of the river Niger (or Quorra, as it was called at Sackatoo), he heard little that could be depended upon. Having returned to England, he was again sent out by the government in command of a new expedition, with instructions that he should endeavour to penetrate to the scene of his former adventures from the coast of Guinea. In the execution of this plan of research he reached the Niger at Boussa, where Park perished; and, after traversing some of the adjoining regions on the farther side of the river, as far as the great commercial city of Kano, the capital of Houssa, where he had been in his former journey, he turned again to the west, and having reached Sackatoo, there died. His servant, Richard Lander, with a praiseworthy zeal, embarked on one of the branches of the Niger for the purpose of finally determining, if possible, its termination by sailing down the stream; but he was stopped by the natives, and compelled to turn back. The city of Timbuctoo was in the meanwhile reached by Major Laing, who succeeded, in August 1826, in making his way thither across the desert from Tripoli. In this famous city he spent some weeks, but was murdered in the desert on his return; nor did the results of his inquiries and observations ever reach Europe. Such are the formidable difficulties and dangers which have hitherto encompassed the path of discovery in the interior of Africa. Still, by renewed efforts, the object of research has been gained. The grand question of the termination of the Joliba, Quorra, or Niger, has at length been fully resolved—a discovery which is the result of the fortunate and well-conducted enterprise on which Richard Lander and his brother were sent out in 1830. Having followed nearly the same route which had been taken by Clapperton in his second journey, these two travellers reached Boussa on the 17th June. They first ascended the river as far as Yaouri, and then returned to Boussa. After remaining there for some time, they embarked on the river to follow the stream in its course downward, hoping that it would conduct them to the sea. In this expectation they were not disappointed; for they reached the Bight of Benin by the larger branch, which is there called the river Nun. There is another great branch a little farther to the south; and by these two outlets, with several smaller channels, the river known in Europe by the name of Niger discharges its waters into the Atlantic.

The zeal for discovery in Africa, which has been so active during the last sixty years, has sent forth a succession of travellers (missionaries and others) to explore the southern regions of that vast continent. We can mention briefly only the most remarkable results of their researches.

It is now (1855) about six years since intelligence was received in Europe of the discovery of snowy mountains in Eastern Africa. The discovery was in itself so remarkable, that the report was not at first universally credited. It was, however, subsequently confirmed. The mountains in question are Kilimanjaro, in about latitude $3\frac{1}{2}^\circ$ S. and longitude 37° E.; and Kenia, in about latitude 1° S., and longitude $38\frac{1}{2}^\circ$ E. They were discovered by the missionaries Rebmann and Krapf, stationed near Mombas. Kilimanjaro is an isolated and very conspicuous peak, probably connected on its western side with the tableland of inner Africa. The missionaries have become acquainted with its eastern, southern, and northern aspects; but Mount Kenia has been seen only from the south, at a distance of six days' journey, or about 80 geographical miles.

Another important discovery made in the interior of Africa within the same time is that of Lake N'Gami, by the missionary the Rev. Dr Livingston, accompanied by Mr Oswell and Mr Murray. It seems to be situated about 19° south latitude—about 560 miles N.N.W. of Kolobeng, the scene of Dr Livingston's missionary labours, and the headquarters of the Baquain tribe. These and other explorers have made us in some measure acquainted with an extensive system of rivers, between 10° and 22° south latitude, running eastward, which, when farther research shall have made them fully known, may be found capable of being rendered subservient to commercial intercourse with the surrounding countries, and to their consequent civilization. Dr Livingston is at present extending his explorations to the north of Lake N'Gami.

An important expedition to Central Africa, headed by Mr James Richardson, left Tripoli in March 1850. It was sent out under the orders and at the expense of the British government. The object of this mission was to survey Lake Tchad, and to explore the neighbouring countries. The scientific interests of the expedition were entrusted to two German gentlemen, Dr Barth and Dr Overweg. Instead of travelling from Tripoli across the desert with the great caravan, the mission formed a small caravan of its own, amounting to about one hundred persons and as many camels. The journey from Tripoli to Murzuk and thence to Ghat is less interesting than that from the latter place, where they entered on entirely new ground. But even in the former part of the march many important discoveries were made, as the travellers selected new routes not before explored, and thus rendered every part of the journey subservient to the purposes of the mission. At Ghat their personal danger was increased to such a degree that they found it necessary to trust for protection to the friendship of the sultan of the Keloës, in whose country they were detained about three months, during which time Dr Barth made an interesting journey to Agadez, while much valuable information was also collected by Mr Richardson and by Dr Overweg who had remained. At the close of 1850 the party reached Zinder, where the three travellers separated, each proceeding with his followers by another route. Mr Richardson took the direct way to Kuka, not far from the shores of Lake Tchad, and the capital of the empire of Bornou. At Kuka all the three hoped again to meet very soon afterwards, but this hope was disappointed. Mr Richardson was of a weak constitution, yet his health appeared to suffer little from the fatigue of crossing the desert; but he sunk before he reached Lake Tchad, which was the termination of his mission, and from which he was to return by direct road to Tripoli. He died in the country of Bornou at Ungurutua, a place six days' journey from Kuka, during the night intervening between the 3d and the 4th of March 1851. Thus was added another name to the large number of those who have fallen a sacrifice to the cause of African discovery.

The two surviving travellers, undaunted by the prospect of danger, proposed as the plan of their operations to approach the Upper Nile, as soon as they had explored the vicinity of Lake Tchad,—provided they were supported by the British and Prussian governments; and to be ready even to pursue their researches from Kuka to the Indian Ocean. The route in a straight line to Mombas lies nearly south-east; but from all they could learn, the route more to the south, in the direction of Lake Nyassi, seemed more practicable. The gigantic journey which they thus contemplated lay through many powerful kingdoms, densely peopled, intersected by numerous rivers, very fertile, and abounding in forests, but where the most formidable obstacles were to be expected from the warlike dispositions of the surrounding nations.

In the meantime they prosecuted with zeal the immediate objects of the mission, embracing every opportunity of collecting information. On the 29th May 1851, Dr Barth started from Kuka to visit the kingdom of Adamana, which, from the accounts he had received, he judged to be the most beautiful country of Central Africa. He reached Yola, the capital, on the 22d June, where he was permitted to remain only three days. He was kindly received, however, both by the sultan and by the inhabitants, and at his departure was treated with consideration and honour. Four days' journey before reaching Yola, he had to cross at the point of their junction the two principal rivers of Adamana, the Benueh and the Faro, the latter being a tributary of the former. The Benueh he describes as the largest and most imposing stream which he had seen since leaving Europe. He found it half a mile broad and about ten feet deep. The distance of the source from the point at which he crossed it was said to be nine days' journey. This magnificent river is in fact the upper course of the Tchadda, which itself falls into the Quorra or Niger, not far from its mouth. The discovery thus made of the identity of the two streams, the Benueh and the Tchadda, has opened up a way of access to the very heart of inner Africa which seems destined eventually to become the line from the west along which the blessings of commerce and civilization are to flow to the surrounding nations. The consideration of the immense importance of following up this discovery, and of the advantages which might be expected to accrue from it, suggested the idea of sending out a steamboat expedition from England to ascend the Tchadda. Former attempts to reach Central Africa by ascending the Quorra had been attended with very disastrous consequences. But the expedition which left the British shores in May 1854 to ascend the Tchadda was eminently successful, while not a single life was lost. It reached the mouth of the Quorra in the beginning of July, and, entering the Tchadda, ascended the stream to within about 50 miles of the confluence of the Benueh and the Faro. Thus it has been fully proved that this important river is navigable to Yola, the capital of Adamana.

While Dr Barth was prosecuting this journey his fellow-traveller was employed in surveying Lake Tchad. This lake is described as an immense marsh, the only portion fit for navigation being a deep channel formed by the river Shary, which pours into the lake a vast volume of water. What Major Denham has described as small islands were found to be extensive meadow-lands of much greater surface than the lake itself. The explorations of Dr Overweg led to results considerably at variance with what had been reported by Denham; but the discrepancies are perhaps more apparent than real, and may find their explanation in the fact that the lake is augmented during the rainy season to an immense body of water; but during the season of drought is so much reduced by evaporation as to appear at times to be almost dried up.

In the course of the summer of 1852, Dr Barth, setting out from Kuka, made a journey in a south-easterly direction towards the Nile; and so near did he approach to the eastern boundary of the basin of that great river that he was able to collect information likely to throw light on some intricate questions connected with it. He succeeded also in exploring a portion of Bagirmi, a powerful kingdom between Lake Tchad and the Upper Nile, which had never before been visited by any European. In uniting, by means of his itineraries, Bagirmi with Dar Fōr, he has completed a line of direct route across Central Africa from the Quorra to the Nile; and thus from the Gulf of Guinea to the Red Sea and the Indian Ocean.

Dr Overweg left Kuka at the same time with Dr Barth, but took a south-westerly direction towards the Quorra. Between the end of March, the time of his setting out, and the end of May when he returned, he successfully performed an important journey, which brought him within 150 English miles of Yacoba, the great town of the Fellatahs. Dr Barth's journey occupied a considerably longer time; and it appears that Dr Overweg's anxiety to await the return of his companion, which was not until the 20th August, induced him to remain at Kuka, notwithstanding the danger to be apprehended from too long exposure to the influence of the unhealthy season. The consequence was, that his constitution became so seriously affected, that though he set out, immediately after Dr Barth's arrival, on an excursion to healthier regions, yet the advantage derived proved only temporary. He died on the 27th September 1852 at Maduāri, about ten miles east of Kuka, and near Lake Tchad.

As it was known that the travellers had expected to be ready to start from Kuka towards the Indian Ocean in August or September 1853, it was intended by their friends in England, that before they left Kuka they should be joined by an additional fellow-labourer to take a part in their arduous undertaking. Dr Vogel, an astronomer and botanist, was accordingly sent out, accompanied by two chosen volunteers from the corps of the Sappers and Miners. By a singular coincidence, on the very morning on which Dr Vogel and his companions went on board the vessel which was to take them to Malta on their way to Tripoli, letters from Dr Barth were received in London announcing the death of Dr Overweg.

Though now left alone, as being the only surviving member of the mission, Dr Barth continued to prosecute with zeal the work in which he was engaged. Up to the 23d November 1852 he was still at Kuka; but he had fixed on the 25th of the same month to leave that place, and to enter on his journey to Timbuctoo. All his journals and papers, arranged and completed up to that date, he intended to forward to Tripoli, there to be deposited with the English consul. By the beginning of March 1853 he had performed more than one-third part of his journey, and had reached the capital of the territories of the Fellātahs, whose friendship and assistance he had secured. After being subjected to the disappointments and delays incident to the traveller in that part of the world, he reached at length the termination of his perilous journey. During his stay at Timbuctoo his life was exposed to great danger, from the influence of unfavourable climate, and much more so from the hostile disposition towards Christians of the most fanatical Mohammedan population of Northern Africa. He thus describes his distressing situation during his sojourn in that magnificent city,—the "Queen of the Desert," as it is justly called by the natives:—"Like a helpless vessel on the ocean waves am I thrown about on a sea of uncertainty between the power and passion of contending parties. Every day brings something new,—now of a satisfactory kind, then again of the reverse. Death, captivity, safe return home, are my visions by turns, and it is yet impossible to say which shall be my fate." To have left Timbuctoo without sufficient protection, would have been to expose himself to certain death. Hence his stay in this place of danger was unavoidably protracted to nearly a year, when he was at last succoured by Auáb, the chief of a Tuarick tribe inhabiting the regions east of Timbuctoo, along the Quorra, who came with an escort of a hundred horsemen, and conducted him in safety through his dominions on his way hack to Sackatoo.

The news of Dr Vogel having been despatched from Europe to join him had reached Timbuctoo before Dr Barth left that place. On the 1st December 1854 he had the inexpressible pleasure of meeting him at Bundi, a small town situated at about 200 geographical miles due west of Kuka. Once more he looked on the face of a European—his countryman—and grasped the hand of a friend in whom he could place implicit confidence. Exactly six years had elapsed since he left Europe, in company with Mr Richardson and Dr Overweg. Since the decease of the latter he had been isolated from civilized society, and had been left to contend single-handed with manifold hardships and dangers. To revisit Europe he now considered as indispensable for the preservation of life and health; and accordingly he moved on to Kuka, whence he intended to proceed homeward without further delay. We are happy to say that he arrived at Marseilles early in September 1855.

The limits of the great unexplored region of Africa may be roughly indicated as extending between the parallels of 10° north and south of the equator, and from Adamaua in the west to the Somauli country in the east. This extensive region has just been touched by the routes of recent travellers. But in all parts of the habitable globe the spirit of research, which has already done so much, is still active; nor is it directed only to the determining of the outlines of continents and countries, or to the marking of the leading features of mountains, rivers and cities, with their relative positions and distances. These are regarded by the geographical inquirer merely as affording a proper basis on which to rest the description of the earth considered as the habitation of man, and as affording him amply the means of improvement and happiness. The picture can be completed only by the continued labours of the scientific observer, who makes the earth, with its various productions, whether natural or artificial, the treasures hid in its bosom, the animals found upon its surface, and, above all, the human beings who people its different regions (and these in all their mutual bearings and relations), the objects of attentive examination and study.

II.—MATHEMATICAL GEOGRAPHY.

CHAP. I.—PRINCIPLES AND DEFINITIONS: OF THE TERRESTRIAL SPHERE.

We have already stated that mathematical geography treats of the figure, magnitude, and motion of the earth; its relations to the other bodies of the system to which it belongs; the relative positions of places on its surface, and the methods of delineating the whole or any part of its surface. Several of these topics belong as much to astronomy as to geography; for the former science regards the earth, on the one hand, as the grand observatory whence the phenomena of the heavens are contemplated by man; and, on the other hand, as itself constituting a portion of the planetary system, the laws of which it is the object of the astronomer to investigate and explain. It is only, indeed, by celestial observation that the position of a point on the surface of the earth can be accurately determined; so that the first principles of geographical science must necessarily be drawn from astronomy.

We take for granted, then, the doctrine of the celestial sphere; the globular form, the magnitude and motion of the earth, with the phenomena arising out of and depending upon its motion. These points are fully discussed in the article ASTRONOMY, part ii. It will be necessary, however, for the sake of distinctness, to state briefly such of the results derived from the reasoning there employed as belong specially to the subject of this article.

The doctrine of the earth's rotundity is that with which the student of geography must first make his mind familiar. To the eye the earth appears a circular plane, at the centre of which the spectator imagines himself placed; whilst the heavens, spread over his head like a magnificent canopy, seem to meet the earth all round in a circle which bounds the view. The space comprehended within this circle is found to present often a very irregular surface, rising into mountains, or sinking into cavities, so as apparently to exclude the idea of its bearing any resemblance to a portion of a globe or sphere. This is, however, nearly its true figure. Were we placed at such a distance from the earth that the eye would be able to take in at one glance the vast mass in its full dimensions, it would present the appearance of a circular disc, of greater or less diameter according to our distance. If viewed on all sides, its circular form would remain unchanged; a property characteristic of no other body but a globe or sphere. The highest mountains would be found to bear so little proportion to the whole bulk, as to cause no perceptible deviation from the globular form; and the same thing may be said of the difference which exists between the polar and equatorial diameters, though that quantity amounts to about twenty-eight miles.

The portion of the earth, then, seen from any point above its surface, is to be regarded as the segment of a sphere, which, increases in extent according as the eye is more elevated. When the semidiameter of the earth, and the height of the eye above the surface are known, it is easy to find the diameter of the circle which bounds our view on the earth; supposing, as is the case at sea, that no object intervenes to obstruct our vision. Thus, let AB be the height of a mountain on the earth's surface. From A draw the line AD, a tangent to the surface in any direction; D will be the most distant point seen by a spectator whose eye is placed at A, the summit of the mountain. If the line AD be supposed to be carried round the point A, while it at the same time continues to be a tangent to the surface, until, having passed through every possible position, it returns to that from which it set out, the point D will trace the circumference of the circle which bounds the terrestrial view, and of which the radius will not differ much from AD. Now AD being a tangent to the arc BD, we have $AD^2 = (2BC + AB) \times AB = 2BC \times AB$ nearly, since AB must always be very small compared with 2BC, the diameter of the earth. Assuming the diameter equal to 7912 English miles, we have $AD^2 = 7912 \times AB$; or, if AB is expressed in feet, $AD^2 = \frac{7912}{5280} \times AB$, in miles. Hence we obtain

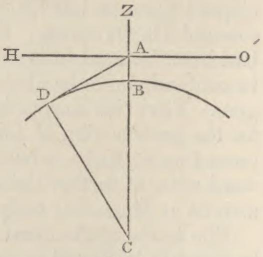

Fig. 1.

$$AD = 1{\cdot}224126\sqrt{AB}.$$

The result obtained from this formula will deviate from the truth in consequence of the effect of refraction; which, at a medium, may be considered as increasing the distance by about $\frac{1}{14}$, or ·0714 of the whole. Applying this correction to the above formula, it becomes

$$AD = 1{\cdot}3115\sqrt{AB}.$$

For example, if the Peak of Teneriffe is 12,358 English feet in height, then $AD = 1{\cdot}3115\sqrt{12358} = 145{\cdot}8$ miles is the radius of the circle which bounds the view from that elevation.

The circle bounding terrestrial vision, which we have now been considering, does not, except when the eye is close to the surface of the earth, coincide with the sensible horizon as determined by a plane passing through the eye along the line HO and perpendicular to the vertical line CZ. The angle contained between the visual ray AD and the horizontal plane is called the *dip* of the horizon. For ordinary purposes, however, it is sufficiently accurate to say that the *sensible horizon* is the circle which bounds the view, where the heavens and the earth appear to meet. To this circle the *rational horizon* is parallel, being determined by a plane passing through the centre of the earth perpendicular to the vertical line CZ, and continued in every direction to the sphere of the heavens.

Let NESQ be the terrestrial sphere, of which C is the centre; and let HO be the rational horizon of the point M. The rotatory motion of the earth determines the position of the line NS on which it revolves, and which is called its *axis.* The two points N, S, in which the axis meets the surface, are called the *poles of the earth.* The circle EQ upon the earth, the plane of which passes through C the centre, and is perpendicular to NS the axis, is called the *equator* or *equinoctial line.* This circle is equidistant from the poles of rotation, and its plane coincides with the plane of the celestial equator. The rational horizon and equator being two great circles of the terrestrial sphere, that is, the plane of each passing through the centre, they are mutually bisected. This is a property which belongs to all great circles. Any great circle NPS passing through the two poles is called a *meridian.* Any given point P may have a meridian passing through it; and the plane of that circle will coincide with the plane of the celestial meridian which passes through the zenith of that point. Every meridian cuts the equator at right angles.

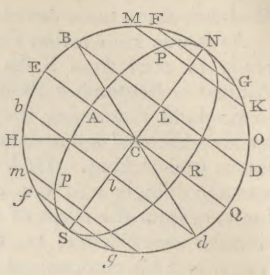

Fig. 2.

The horizon HO corresponding to any point M upon the globe, is divided into four equal parts by the equator and the meridian passing through that point. The points of division are called the four *cardinal points.* Those through which the meridian passes are called the *north* and *south* points of the horizon. Those points, again, through which the equator passes are called the *east* and *west* points.

The earth is divided by the horizon into two hemispheres, called the *upper* and *lower* or *under hemispheres;* by the equator it is divided into the *northern* and *southern hemispheres;* and by the meridian, into the *eastern* and *western hemispheres.*

The position of any point P on the surface of the earth is determined by referring it to the co-ordinate circles, the equator and meridian. The distance PA of the place P from the equator, measured in degrees and parts of a degree on the meridian passing through the place, is called its *latitude,* which is said to be north or south, according as the place is situated in the northern or southern hemisphere. The arc EA of the equator, intercepted between the meridian passing through the place P and some particular meridian NMS, called the *first meridian,* as being that fixed on from which the reckoning is to commence, is called the *longitude* of the place in question; and is east or west, according as the place is situated in the eastern or western hemisphere in reference to the first meridian. The difference of longitude between two places is the arc of the equator intercepted between their meridians; and is found by subtracting or adding the longitudes, according as the places are on the same or on opposite sides of the first meridian. The ancients assumed for their first meridian that of the Fortunate Islands, which they conceived to be the western limit of the habitable world. In later times, the meridian passing through Ferro, one of the Canary Islands, was used as the first meridian by the geographers of many countries. It nearly coincided with that of the ancients. But in modern systems of geography the first meridian is usually that which passes through the capital of the country to which the geographer belongs; or if there is an observatory in or near the capital, the meridian of the observatory is assumed as the first. By British geographers the meridian of the observatory at Greenwich is reckoned the first meridian. It is usual to call the semicircle NPS, passing through the two poles and a given place, the meridian of that place; and the other semicircle NRS passing through the opposite point on the globe, the opposite meridian. All places lying under the same meridian have the same longitude, and at all of them noon or any other hour occurs at the same instant of absolute time. As the sun in his apparent diurnal revolution moves over fifteen degrees in an hour, it is evident that difference of longitude, which causes difference in the rela-

Mathematical Geography.

tive time, may be estimated in time, allowing fifteen degrees to an hour, or one degree to four minutes.

If a small circle MPK, or *mpk*, be drawn parallel to the equator at any distance from it, all the places through which that small circle passes will have the same latitude. Such small circles are accordingly called *parallels of latitude.* The difference of latitude between two places is the arc of the meridian intercepted between their parallels of latitude, and is found by subtracting or adding the latitudes, according as the places lie on the same or on opposite sides of the equator.

On the hypothesis of the earth being a perfect sphere, the degree of latitude must be assumed as everywhere of the same length. Actual observation shows that this is not exactly the case, but that the length of the degree increases slightly as we proceed from the equator towards either pole (see FIGURE OF THE EARTH), so as to indicate a flattening of the surface in the latter regions, or that the earth is of a spheroidal figure. This, however, we do not at present take into view. With regard to the degree of longitude, it is at the equator of the same length with the degree of latitude. But on both sides of the equator it decreases gradually on account of the meridians approaching each other until they intersect at the poles. At the equator a degree of longitude is the 360th part of the circumference of a great circle of the terrestrial sphere; at every point to the north or south of the equator it is the 360th part of the circumference of a small circle, of which the radius is equal to the cosine of the latitude. Now, since similar portions of the circumferences of circles are to one another as their radii, if we put L for the length of the degree of longitude at the equator, and L′ for its length in a latitude denoted by l, we have rad. : cos. l : : L : L′. Hence, radius being unity, we obtain

$$L' = L \times \cos. l.$$

From this formula the following table is calculated; the length of the degree of longitude at the equator being assumed equal to 69·06 English miles.

Table showing the Length of a Degree of Longitude for every Degree of Latitude, in Geographical and in English Miles.

Lat.	Geo. Miles.	Eng. Miles.	Lat.	Geo. Miles.	Eng. Miles.	Lat.	Geo. Miles.	Eng. Miles.

Mathematical Geography.

If a great circle B*d* be supposed to be drawn on the terrestrial sphere, cutting the equator obliquely at an angle of about 23½ degrees, this circle will mark out the course of the sun through the year, and is called the *ecliptic.* It corresponds with the celestial ecliptic, and is divided in the same manner into signs and degrees. The parallel of latitude which passes through the point of the ecliptic in which the sun is placed on any particular day, shows to what points of the earth's surface the sun is vertical on that day. The two parallels BLD, *bld,* which touch the ecliptic at the points where it recedes farthest from the equator to the north and south, are called the *tropics;* the one, BLD, the northern tropic, or the tropic of Cancer; and the other, *bld,* the southern tropic, or the tropic of Capricorn; because they touch the ecliptic in the first points of these signs. These circles lie in the planes of the corresponding circles in the celestial sphere.

Of the two poles, that which lies in the northern hemisphere is called the *north* or *arctic pole;* and the opposite, lying in the southern hemisphere, is called the *south* or *antarctic pole.* The two parallels of latitude FG, *fg,* which encircle these poles respectively at an angular distance equal to the obliquity of the ecliptic, are called the *polar circles,* the one the north or arctic, and the other the south or antarctic.

Suppose a great circle to be drawn on the terrestrial sphere everywhere equally distant from that point on the surface to which the sun is vertical at any given time; this circle is called the *circle of illumination,* because it separates the enlightened from the dark hemisphere of the earth. It is upon the position of the circle of illumination that the equal or unequal lengths of the days and nights throughout the year depend over the face of the earth. At every season of the year this circle bisects the equator, so that under the equator the days and nights are always equal. When the sun is over either of the equinoctial points E, Q, the circle of illumination bisects not only the equator, but likewise all the parallels to the equator, in consequence of cutting them at right angles; and hence, as the parallel of latitude passing through any point on the earth's surface may be regarded as the path along which that point is carried by the diurnal motion of the earth, at that season of the year the days and nights are equal over all the earth. When the sun is over any other point of the ecliptic, the parallels of latitude are cut obliquely by the circle of illumination, so that they are divided by it into two unequal parts, and hence the days and nights are unequal all over the earth, except at the equator. If the sun is in north declination, at all places to the north of the equator the days are longer than the nights; but at all places to the south of the equator, the nights are longer than the days; because with regard to places to the north, the larger portion of the parallel of latitude lies within the enlightened hemisphere, while with regard to places to the south the larger portion lies within the dark hemisphere. The reverse has place when the sun is in south declination. When the sun is over the northern tropic BD, or over the southern tropic *bd,* the day is then the longest or shortest of the year; and the adjacent polar circle is wholly in the light, and the opposite one wholly in darkness.

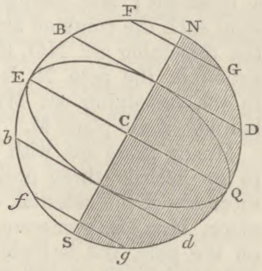

Fig. 3.

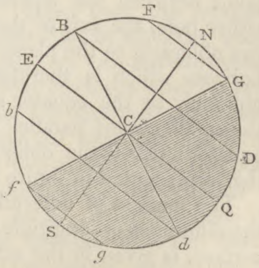

Fig. 4.

Mathematical Geography.

Mathematical Geography.

Thus within the arctic and antarctic circles the inhabitants have their light and darkness extended to a great length; the sun sometimes skirting round a little above the horizon for many days together, and at another season never rising above the horizon at all, but making continual night for a considerable length of time.

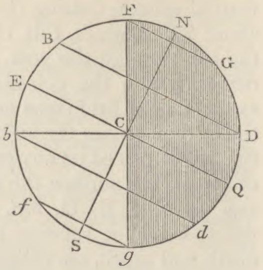

Fig. 5.

Such are the circles supposed to be drawn on the terrestrial sphere. Though these circles are altogether imaginary, and have really nothing corresponding to them on the earth's surface, yet as the positions of the corresponding circles in the heavens can be accurately determined by observation on the celestial bodies, they become actually as effective for fixing the relative positions of places on the globe of the earth, and for other purposes of geography, as if that globe were reduced to such a magnitude as to admit of its being grasped by the hand of man, and surveyed by a single glance of his eye.

The height NO of the pole adjacent to any place M above HO the horizon of that place, is equal to the latitude of the place; for the arcs MO and EN are equal, each being a quadrant; and taking away from each the common arc MN, the remaining arc NO, the elevation of the pole N, is equal to the remaining arc ME, the latitude of the place M.

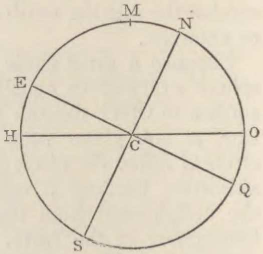

Fig. 6.

Hence there are, with regard to the horizon, three positions of the terrestrial sphere, as there are of the celestial, depending on the latitude of the place. If an observer were placed on the pole, the latitude being 90°, his horizon would coincide with the equator, and all the parallels of latitude would be parallel to the horizon. This is the parallel position of the sphere, which is represented in fig. 7. Again, if an observer were placed on any point of the equator, the latitude being 0, the poles of the earth must be in the horizon; and from the properties of the sphere, the equator, and all the small circles parallel to the equator, must be at right angles to the horizon. This is the right position of the sphere, which is represented in fig. 8. With regard to an observer placed at any point between the equator and either pole, the axis of the earth lies obliquely to the plane of his horizon, which is therefore cut obliquely by the equator and all the small circles parallel to the equator: this is the oblique position of the sphere, and is that represented in figure 2.

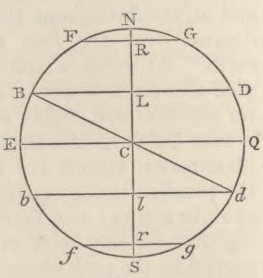

Fig. 7.

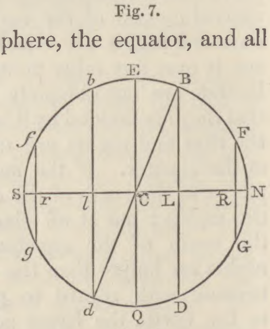

Fig. 8.

The method of determining the latitude of a place, and the difference of longitude between two points on the earth's surface, is given in the article ASTRONOMY, part iv. chap. i. prob. ix. and x. The latitudes and longitudes of two points on the surface of the earth being given, the angular distance may be found; and hence the length of a degree on the earth's surface being known, the distance between the points may be expressed in miles. Thus, let A and B be two points on the earth's surface, let P be the adjacent pole, and PA, PB the meridians passing through A and B; then PA and PB will be the complements of the latitudes, and therefore given; and the spherical angle APB will be the difference of the longitudes, and therefore also given. In the spherical triangle PAB, the base AB of which is the distance required, we have therefore two sides and the included angle, so that the base AB can be found. Put D and D' for the complements of the given latitudes, and P for the difference of the given longitudes; then, by spherical trigonometry, we have

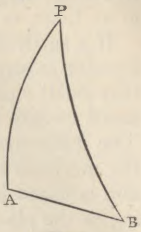

Fig. 9.

$$\text{Cos. AB} = \text{cos. D cos. D}' + \text{sin. D sin. D}' \text{ cos. P.}$$

By assuming tan. ϕ = tan. D cos. P, this formula may be reduced to the more convenient form

$$\text{Cos. AB} = \frac{\text{cos. D cos. }(\text{D}' - \phi)}{\text{cos. }\phi}.$$

From the above expression the number of degrees and parts of a degree contained in the arc intercepted between the points A and B are to be found; and allowing for each degree 69·06 English miles, the distance will be obtained, expressed in English miles, which will necessarily differ a little from the truth, in consequence of the earth not being truly spherical. To determine the distance between two points on the earth's surface with precision, requires the application of some of the most refined improvements in modern mathematics. See FIGURE OF THE EARTH.

As an example of the above formula, let it be required to find the distance between Edinburgh and Constantinople.

Colat. of Edinburgh......34° 3' = D : its long. 3° 12' W.

Colat. of Constantinople 48° 59' = D': its long. 28° 55' E.

Difference of longitude......= 32° 7' = P.

Tan. D = tan. 34° 3' = 9·829805

Cos. P = cos. 32° 7' = 9·927867

Tan. φ, 29° 47'.......... 9·757672

D' = 48° 59'

D' — φ = 19° 12'.......... Its cosine = 9·975145

Cos. D = 9·918318

Arith. compl. cosine φ = 0·061525

Cos. AB, 25° 38'...= 9·954988

Hence the arc of a great circle of the sphere intercepted between Edinburgh and Constantinople is 25° 38', or 1770 English miles nearly.

Each of the four quadrants into which the horizon is divided by the equator and the meridian is supposed to be divided into eight equal parts; so that the whole circumference is divided into thirty-two equal parts, which are called *points of the compass*; and to each point of division a name is given indicating its position with regard to the four cardinal points.

The position of one place with regard to another, as estimated by the points of the compass, is called the *bearing* of the former from the latter. Thus, when a place is said to bear N.E. (north-east), N.N.E. (north-north-east), &c. the meaning is, that it lies in the direction of those points in the horizon from the present position of the observer. If a series of points be assumed on the earth's surface, so situated that all of them, when taken in regular succession, lie towards any the same point of the compass, except either of the four cardinal points, the assumed points lie, not in the circumference of a circle of the sphere, but in a sort of spiral line, the characteristic property of which is, that it cuts all the meridians at the same angle. This line is called a *rhumb line*; and, whilst it continually approaches the pole, it can never arrive at it, except after an infinite number of revolutions. In passing, therefore, from one point of the surface of the globe to another, by pursuing the direction in which the latter lies from the former, we do not take the shortest way, which is an arc of a great circle, but move over a portion of a rhumb line, passing through the two points. This is the line described by a ship whilst her course is continually directed towards one and the same point of the compass.

CHAP. II.—OF THE SURFACE OF THE EARTH, AND ITS GENERAL DIVISIONS: DEFINITIONS.

The surface of the earth contains about 196,663,400 square miles. By much the larger portion of this space is water, which is, indeed, more than twice the extent of the land. The surface of the land is exceedingly diversified, almost everywhere rising into hills and mountains, or sinking into valleys, and sometimes stretching out into plains of great extent. Amongst the most extensive plains are the sandy deserts of Arabia and Africa, the internal part of European Russia, and a tract of considerable extent in Prussian Poland. But the most remarkable extent of level ground is the vast table-plain of Thibet in Asia, which is the most elevated tract of level ground on the globe. The principal mountain ridges are the Alps and Pyrenees in Europe, the Altai and Himalaya Mountains in Asia, the mountains of Atlas in Africa, and the Andes or Cordilleras in South America. The greatest concavities of the globe are those which are occupied by the waters of the ocean; and of these by far the largest forms the bed of the Pacific Ocean, which, stretching from the eastern shores of Asia and of New Holland to the western coast of America, covers nearly half the globe. The concavity next in extent is that which forms the bed of the Atlantic Ocean, extending between the new and the old worlds; and a third concavity is occupied by the Indian Ocean. The Arctic and Antarctic Oceans fill up the remaining concavities.

Smaller collections of water which communicate freely with the oceans are called *seas*; and of these, the principal are the Mediterranean, the Baltic, the Euxine or Black Sea, and the White Sea. Seas sometimes take their names from the countries near which they flow; as the Irish Sea, the German Ocean. Some large collections of water, though they have no immediate connection with the great body of waters, being on all sides surrounded by land, are yet called seas; as the Caspian Sea.

A part of the sea running up into the land, so as to form a large hollow, is called a *bay* or *gulf*, as the Bay of Biscay, the Gulf of Mexico; but if the hollow be small, it is called a *creek*, a *road*, a *haven*.

When two large bodies of water communicate by a narrow pass between two adjacent lands, the pass is called a *strait* or *straits*, as the Straits of Gibraltar, the Straits of Dover, the Straits of Babelmandel. A channel is a wider kind of strait. The water usually flows through a strait with considerable force and velocity, forming what is called a *current;* and frequently this current, as in the case of the Straits of Gibraltar, flows continually in the same direction.

A body of fresh water entirely surrounded by land is called a *lake*, as the Lake of Geneva, Lake Champlain.

A considerable stream of water rising inland, and draining a portion of country more or less extensive, discharging its waters into the sea, is called a *river*. A smaller stream of the same kind is called a *rivulet*, or *brook*.

Of the land, which forms the rest of the surface of the globe, two portions of vast extent are called *continents;* the one the eastern continent, or the old world, comprehending Europe, Asia, and Africa; the other the western continent, or new world, comprehending North and South America. New Holland is a third portion of land, however, which has by some been also reckoned a continent on account of its great extent.

A portion of land, of comparatively small dimensions entirely surrounded by water is called an *island*, as Britain, Ireland, Jamaica, Madagascar. New Holland is the largest portion of land which is called an island. When a number of smaller islands lie near each other they are said to form a *group* of islands.

A portion of land which is almost entirely surrounded by water is called a *peninsula*, as the peninsula of Malacca, the Morea or Grecian Peloponnesus, &c. The term peninsula is often applied to a large extent of country. Thus we speak of Spain as a peninsula.

The narrow neck of land which joins a peninsula to the mainland, or which connects two tracts of country together, is called an *isthmus*. The most remarkable isthmuses in the world are the Isthmus of Suez which joins Africa and Asia, and the Isthmus of Darien which connects the continents of North and South America.

A narrow tract of land stretching out into the sea, and appearing to terminate in a point, is called a *cape*. The most remarkable capes are, the Cape of Good Hope, at the southern extremity of Africa; Cape Horn, at the southern extremity of South America; and the North Cape, at the northern extremity of Europe. A large portion of land jutting out into the sea is called a *promontory*.

Until of late, in systems of geography, the earth used to be considered as divided into four quarters; Europe, Asia, Africa, and America. A classification in which the whole world is arranged under seven divisions has now, however, been very generally adopted: These divisions are, Europe, Asia, Africa, North America, South America, Australasia, and Polynesia. With regard to the last two, the one, Australasia, or South Asia, comprehends certain of the great islands, particularly New Holland, which are usually considered as belonging to Asia; and the other, Polynesia, signifying many islands, comprehends all the smaller islands which are scattered over the great expanse of the Pacific Ocean.

This classification of the parts of the earth's surface is founded on the most obvious points of distinction. We shall now explain two divisions employed by the ancients, which are founded upon different principles; that into zones, and that into climates.

The division into zones is suggested by the different degrees of temperature which prevail in different regions of the earth. The temperature of a country depends on a variety of circumstances (see PHYSICAL GEOGRAPHY); but of these, one of the most obvious is the position of the sun with regard to the zenith. The more nearly his rays are received vertically, the higher will be the temperature; and, on the contrary, the more obliquely they fall, the less effect will they produce in raising the temperature. Now to every point of the earth's surface between the tropics the sun is vertical twice in the year. It is in this region, then, that the highest temperature will prevail. Again, within the polar circles the sun's rays at all times fall very obliquely; and for a length of time they do not reach these two regions of the globe at all. Here, then, the temperature must be lower than anywhere else, as all other places enjoy more of the sun's genial influence. In the two regions between the tropics and the polar circles, a medium temperature is found, increasing as we approach the former, and diminishing as we approach the latter. Thus is the earth's surface divided, by the two tropics and two polar circles, into five *zones*, distinguished from one another by the prevailing temperature in each. That between the tropics is called the *torrid zone*, because there the heat is understood to be extreme. This region, which has the equator passing through the middle of it, the ancients, indeed, considered as uninhabitable. The two regions comprehended within the arctic and antarctic polar circles are called the northern and southern *frigid zones*, on account of the severity of the cold which there prevails. The two regions situated between the tropics and the polar circles, the one in the northern hemisphere, bounded by the tropic of cancer and the arctic circle, the other in the southern hemisphere, bounded by the tropic of capricorn and the antarctic circle, are called the northern and southern *temperate zones*, because there neither the heat nor cold is excessive; but the heat reaches the highest temperature of summer, and the cold sinks to the lowest temperature of winter, without either becoming extreme.

As each tropic lies about $23\frac{1}{2}°$ from the equator, the breadth of the torrid zone is about 47°, or nearly 3240 English miles. The breadth of each of the frigid zones, that is, from the circumference of the polar circle to the pole, is $23\frac{1}{2}°$, or nearly 1620 miles; so that there remains for the breadth of each of the temperate zones about 43°, or nearly 2970 miles. The superficial content of each zone is easily calculated by the ordinary rules of mensuration. Let s be the surface of a segment of the sphere, d the diameter of the sphere, and h the height of the segment; then

$$s = 3{\cdot}1416\,dh.$$

To apply this formula; let NESQ be the sphere divided into five zones. It is evident that, for the torrid zone, h must be equal to $\mathrm{L}l$, or to twice the sine of BE to the radius EC; that for each of the temperate zones h must be equal to LR or lr, the difference of the sines of FE and BE to the same radius CE; and that for the space comprehended within each polar circle, h must be equal to NR, the excess of the radius NC above CR, the sine of FE corresponding to that radius. Hence, if we put m for twice the natural sine of the arc BE; for the difference of the natural sines of the arcs BE and FE; and for the excess of radius above the natural sine of FE, successively;—since in the case of the terrestrial sphere CE or CN is equal to 3956 miles, we have $h = 3956\ m$. Putting, therefore, instead of d, its value, 7912, and giving the above formula a logarithmic form, we obtain

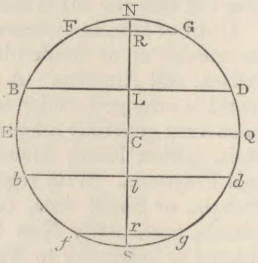

Fig. 10.

$$\text{Log. } s = \text{log. } m + 7{\cdot}9926935.$$

Now, for the torrid zone, $m = 2$ nat. sin. $23° 30' = {\cdot}7975$. Hence,

$$\text{Log. } m = \bar{1}{\cdot}9017307$$
$$7{\cdot}9926935$$

$$s = 78419520 \ldots\ldots\ldots\ldots \text{log.} = 7{\cdot}8944242.$$

The torrid zone contains, therefore, about 78,419,500 square miles.

Again, for each of the temperate zones, we have m = nat. sin. $66° 30'$ − nat. sin. $23° 30 = {\cdot}51831$. Hence,

$$\text{Log. } m = \bar{1}{\cdot}7145896$$
$$7{\cdot}9926935$$

$$s = 50966300 \ldots\ldots\ldots\ldots \text{log.} = 7{\cdot}7072831.$$

So that each of the temperate zones contains about 50,966,300 English square miles.

Lastly, for the space contained within each of the polar circles we have m = rad. − sin. $66° 30' = 1 - 0{\cdot}91706 = {\cdot}08294$: Hence,

$$\text{Log. } m = \bar{2}{\cdot}9187640$$
$$7{\cdot}9926935$$

$$s = 8155630 \ldots\ldots\ldots\ldots \text{log.} = 6{\cdot}9114575.$$

The portion of the surface of the globe comprehended within each polar circle is therefore nearly equal to 8,155,600 square miles.

It is evident that the superficial content of any other zone of the terrestrial sphere may be found by the above formula, by putting m equal to the difference of the natural sines corresponding to the latitudes of the parallels by which the zone is bounded.

If it is required to find the area of a segment of a zone bounded at both extremities by meridians, it is only necessary to find first the area of the whole zone, and then to multiply the result by the number of degrees and parts of a degree in the length of the segment, and to divide by 360. Thus, the number of square miles contained in the portion of the torrid zone terminated by two meridians which are separated from each other by 8° 45′ is equal to $78419520 \times 8\frac{3}{4} \div 360$, which gives 272,290 square miles. By dividing any particular country or district into segments of zones by means of parallels of latitude, its area can easily be calculated.

The division of the earth's surface into climates was employed by the ancients for ascertaining the situation of places. They supposed the northern and southern hemispheres to be each divided into small zones, to which they gave the name of *climates*, the breadth of each zone being such as to make half an hour of difference in the length of the longest day at the two parallels of latitude by which the climate was bounded. Proceeding from the equator, where the length of the day is always twelve hours, they thus divided the space between it and each polar circle into twenty-four climates. Having reached the polar circles northward and southward, where the longest day is twenty-four hours, they divided the space within each polar circle in such a manner as to make the difference in the length of the longest day at the beginning and termination of each climate one month. Hence, as the poles are alternately illuminated for six months, there were just six climates within each polar circle.

Besides dividing the surface of the globe into zones and climates, the ancients likewise distinguished the inhabitants of the different regions of the earth by the particular direction in which the shadows of bodies are projected in each region, and by some other circumstances depending on the position of the sun relatively to the zenith or to the meridian. The inhabitants of the torrid zone have their shadows at noon projected, sometimes towards the south and sometimes towards the north, according to the position of the sun in the ecliptic. They were therefore called by the ancients *Amphiscii*, a term derived from αμφι, *about*, and σκια, *a shadow*. In the temperate zones, the sun is at noon always on the same side of the zenith. Hence the shadows of objects at noon always fall in the same direction; in the northern temperate zone towards the north; and in the southern temperate zone towards the south. The inhabitants of these regions were accordingly called *Heteroscii*, from ἑτερος, *different*, and σκια. Within the polar circles the sun does not always rise and set every twenty-four hours, as in the other zones; but for a certain number of days in our summer he never sets to places within the arctic polar circle, nor rises to places within the antarctic; and the contrary takes place for a certain number of days during our winter. The number of days during which the sun is present or absent increases as we advance from the polar circle towards the pole. When the sun continues above the horizon for twenty-four hours or upwards, the shadows will make a complete circuit round the objects from which they are projected; hence the inhabitants of the frigid zones were called *Periscii*, from περι, *about*, and σκια.

Again, the inhabitants of two places which lie under the same meridian, and have the same latitude, but are situated on opposite sides of the equator, were called, relatively to each other, *Antœcii*, from αντι, *opposite to*, and οικια, *a habitation*. At such places the hours of the day will always correspond, but the seasons of the year will be opposite. The inhabitants of two places which have the same latitude, and are situated on the same side of the equator, but under opposite meridians, were called *Periœcii*, from περι, *about*, and οικια. They have always the same season of the year at the same time; but any hour of the day at the one place corresponds to the same hour of the night at the other. The inhabitants of two places which have the same latitude, but are situated on opposite sides of the equator, and under opposite meridians, are called *Antipodes* to each other, from αντι, *opposite to*, and πους, *a foot*. They have always opposite seasons and opposite hours.

CHAP. III.—DESCRIPTION AND USE OF THE GLOBES.

When geographers became familiar with the doctrine of the sphericity and motion of the earth, it was an obvious step to have recourse to an artificial sphere for illustrating that doctrine. From a very early period, accordingly, the instruments called the *terrestrial* and *celestial globes* have been employed for this purpose. A sphere made of metal, ivory, plaster, paper, pasteboard, or some other convenient substance, is suspended in a brass ring, of somewhat greater diameter, on two pins, upon which it can be made to revolve. The sphere, thus suspended, is placed in a frame, which may be in many respects variously constructed, according to the taste of the workman; but its upper part always consists of a broad ring made of metal or wood, and supported in a horizontal position. The inner circumference of this ring is equal to that of the brass circle in which the globe is suspended; and two notches in its inner edge, diametrically opposite to each other, receive the brass ring, which also rests in a groove below, in such a position that the plane of the horizontal ring bisects the sphere. By this arrangement the globe can be made to revolve on its axis, and the brass circle can be made to slide round in its own plane. On the surface of the globe are delineated the equator or equinoctial line, situated exactly in the middle between the two points on which the globe is suspended, and divided into 360 degrees; the ecliptic, divided into twelve signs, and each of these subdivided into thirty degrees; the two tropics; the two polar circles, with as many more parallels to the equator as are found convenient; and generally twenty-four meridians passing through the points of suspension, which represent the poles. The first meridian is usually made to pass through the intersections of the equator and ecliptic, the points of the vernal and autumnal equinoxes; and from the former of these points the reckoning of the degrees on the equator and ecliptic begins. The brass circle in which the globe hangs may be made to represent the meridian of any given point on the surface of the globe, by simply bringing the given point under it by turning the globe round on its axis. Hence the brass circle is called the *universal meridian*. It is divided, by the equator and two poles, into four quadrants, each of which is graduated; and on the one semicircle the degrees are reckoned from the equator towards either pole, while on the opposite semicircle they are reckoned from either pole towards the equator. On the broad horizontal circle of the frame in which the globe stands are drawn several concentric circles, the outer of which is divided into 365 equal parts, answering to the number of days in the year; whilst the other circles are graduated, the innermost (or rather another circle concentric with it, but larger) being, besides, divided into thirty-two equal parts corresponding to the points of the compass. The circle next the outer edge forms the calendar, and it has the names of the months arranged in order around it, whilst the divisions are distributed so as to mark the number of days in each. The adjacent circle contains the signs and degrees of the ecliptic, so arranged that against each day of the year is found the point of the ecliptic in which the sun is situated on that day. The innermost circle represents the horizon; and the two notches in which the brazen meridian rests pass through the north and south points. It is divided into four quadrants by the cardinal points; and the degrees of the two quadrants, which form the northern semicircle, are reckoned from the east and west points towards the north; while the degrees of the other two quadrants are reckoned from the east and west towards the south.

Such is a general view of the parts which belong alike to both globes, the terrestrial and the celestial. A more minute description seems unnecessary, as a careful inspection of the globes themselves, with their appendages, will convey a much more distinct conception of them than can be given either by description or by drawings. It will be necessary, however, to describe shortly the horary or hour circle, the quadrant of altitude, and the compass.

The hour-circle is a small circle of brass, divided into twenty-four equal parts corresponding to the hours of the day, the divisions being reckoned in two twelves to suit the hours before and after noon. The circle is fixed on the axis of the globe, having its centre coinciding with the north pole. It can be adjusted with the hand to any meridian, but is at the same time tight enough to be moved along with the globe. Some globes have the hour-circle fixed on the meridian, with an index that admits of being adjusted with the hand, but is carried round with the globe.

The quadrant of altitude is a thin flexible slip of brass, equal in length to one-fourth part of the circumference of a great circle on the globe. It is graduated on one side, and is furnished with a nut and screw at one end, for the purpose of making it fast to the brazen meridian. Its use is to measure degrees on the surface of the globe in any direction.

The compass is simply a magnetic needle suspended over the centre of a circle, on the circumference of which are marked the thirty-two points of the compass. It is fixed to the under part of the frame in which the globe is suspended, and is used for the purpose of placing the meridian due north and south.

On the terrestrial globe the land and water which compose the surface of the earth are delineated, with the various divisions belonging to each. If we suppose the globe to be six or seven feet in diameter, the true height of the mountains on the earth's surface must be reduced, in order to be represented on the globe in due proportion to its bulk, in the ratio of 7912 miles to six or seven feet; that is, the height of the protuberance on such a globe which shall represent any particular mountain must be somewhat about the six-millionth part of the actual elevation of the mountain above the general surface of the earth. Apply this to the highest mountain in the world, which does not exceed five and a half miles in height; the elevation of the protuberance representing it on a globe of the supposed dimensions would be about one-seventeenth part of an inch above the general surface. It is seldom, however, that globes are made of this size. One-third of the supposed diameter is more near to the ordinary dimensions. Hence we see with what propriety the earth is represented by a globe having a smooth surface.

But in order to render the representation more complete, it may be supposed necessary that the terrestrial globe should be inclosed in a hollow sphere which would represent the heavens surrounding the earth on all sides. In conformity with this idea the *armillary sphere* was contrived, in which the several circles of the system of the world, put together in their natural order, are represented, with a small globe in the centre of the sphere to represent the earth. The ordinary way, however, of representing the heavens, proceeds on the supposition that the eye of the observer is placed, not in the centre of the celestial sphere, but beyond its bounds, so as to look down on a *convex* surface. Thus are the stars and constellations represented in their relative positions on the celestial globe, with which the concave surface of the visible heavens is easily compared.

Besides answering the general purposes of illustration, the globes furnish also the means of resolving with facility, and with a degree of accuracy sufficient for ordinary purposes, many problems in geography and practical astronomy. It is only requisite to consider the circumstances on which the solution of a problem depends, and to arrange on the globe these circumstances, according to their natural order and dependence, and the result is at once obtained. We proceed to give a few of the more useful problems, with their solutions by the globes.

I. *Solution of Problems by the Terrestrial Globe.*

Prob. 1. To find the latitude and longitude of a given place.

Bring the place under the graduated edge of the brazen meridian, then the degree of the meridian immediately over it is its latitude north or south, and the degree of the equator cut by the meridian is its longitude east or west.

Prob. 2. The latitude and longitude of a place being given, to find the place itself on the globe.

Bring the point of the equator corresponding to the given longitude to the brazen meridian; under the degree of latitude on the meridian the place is found.

Prob. 3. To find the distance between any two places on the globe.

Lay the quadrant of altitude over the two places, and mark the number of degrees between them. The degrees may then be converted into English miles, if required, by multiplying by 69·06.

Prob. 4. The hour at any one place being given, to find what hour it is at any other place; or to find the difference of longitude between the places in time.

Bring the place at which the hour is given to the brazen meridian, and set the index, or the hour-circle, to that hour; then turn the globe till the other place comes under the meridian, and the index, or the hour-circle, will show the hour required. The difference between the time found and the time given is the difference of the longitudes of the places in time.

Prob. 5. To rectify the globe for a given place.

Elevate the pole that is adjacent to the place as many degrees above the wooden horizon as are equal to the latitude.

Prob. 6. To find at what hour the sun rises and sets at a given place, for any given day.

Rectify the globe for the latitude of the place; find from the wooden horizon the sun's place in the ecliptic for the given day, and bring it to the meridian. Set the index to XII., and turn the globe till the sun's place comes to the eastern edge of the horizon, the index will show the hour of rising; then turn the globe till the sun's place comes to the western edge of the horizon, and the index will show the time of setting.

By doubling the hour of sunrise, we obtain the length of the night; and by doubling the hour of sunset, we obtain the length of the day. It is evident also that the same arrangement of the globe will give the point of the compass on which the sun rises and sets, by simply observing what point of the circle of rhumbs, on the wooden horizon, is cut by the sun's place in the ecliptic at the time of rising and setting. Further, by observing when the sun is about eighteen degrees below the eastern and western parts of the horizon, the time of the beginning of the morning twilight, and of the ending of the evening twilight, is found.

Prob. 7. To find the sun's declination for a given day of a given month, and to what places the sun will be vertical on that day.

Find, on the wooden horizon, the sun's place in the ecliptic for the given day; bring that point of the ecliptic to the meridian, the degree immediately over it on the meridian is the declination north or south. Turn round the globe till it has made a complete revolution; and to every place which passes under that degree of the meridian, the sun will be vertical on that day.

Prob. 8. The hour and day being given at a particular place, to find where the sun is then vertical.

Find the sun's declination by the preceding problem; bring the given place under the meridian, and set the index to the given hour; then turn the globe till the index points to XII. noon; and all the places under the meridian will have noon at the given time; and that place which is under the degree of the meridian that corresponds with the sun's declination will have the sun in the zenith.

Prob. 9. The hour and day being given at a particular place, to find where the sun is then rising or setting, and where it is noon or midnight.

Rectify the globe for the given place; and having previously found by last problem the place to which the sun is vertical at the given time, bring that place to the meridian. Then, to all the places under the western edge of the horizon the sun is rising, and to those under the eastern he is setting; to those under the upper half of the meridian it is noon, and to those under the lower half it is midnight.

Prob. 10. A place in the torrid zone being given, to find on what two days of the year the sun will be vertical to that place.

Find the latitude of the place; turn round the globe, and note the two points of the ecliptic which pass below the degree of latitude on the meridian. Find in the calendar circle of the wooden horizon the days corresponding to these two points of the ecliptic, and these are the days required.

Prob. 11. To find the sun's meridian altitude at a given place on a given day.

Rectify the globe for the latitude of the place; bring the sun's place for the given day to the meridian; count the number of degrees between that place and the horizon for the altitude required.

Prob. 12. To find the altitude of the sun at any given place and hour.

Rectify the globe for the latitude; bring the sun's place to the meridian, and set the index to XII. noon; turn the globe till the index point at the given hour; fix the quadrant of altitude on the meridian at the degree of latitude, and lay it over the sun's place; count the number of degrees on the quadrant between that point and the horizon for the altitude required.

Prob. 13. To find all the places to which a lunar eclipse is visible at any instant.

Find the place to which the sun is vertical at the given time; rectify the globe for the latitude of that place, keeping the place under the meridian; set the index to XII. noon; then turn the globe till the index point to XII. midnight; the eclipse will be visible to all those places which are above the horizon.

Prob. 14. Any place in the north frigid zone being given, to find how long the sun shines there without setting, and how long he is totally absent.

Rectify the globe for the latitude of the place; bring the ascending signs of the ecliptic to the north point of the horizon, and note at what degree the ecliptic is intersected by that point; find on the wooden horizon the day and month corresponding to that degree; from that day the sun begins to shine continually. Next, bring the descending signs to the north point of the horizon, and by observing at what degree the ecliptic is now cut, and referring to the horizon, we find the time when the sun ceases to shine without setting, which is the termination of the longest day. By proceeding in the same manner with the southern point of the horizon, we will find the beginning and end of the longest night.

Prob. 15. Two places being given, to find tne angle which a great circle passing through them makes with the meridian of each.

Rectify the globe for both places successively, bringing in each case the place for which the globe is rectified to the meridian; fix the quadrant of altitude in each operation on the meridian over the place for which the globe is rectified, and lay it over the other place; the two arcs intercepted successively on the horizon between the quadrant and the meridian measure the angles required. It is evident, that if both places lie on the same meridian the angle is 0; and that if both lie on the equator the angles will be each 90°

If a ship be supposed to sail from the one place to the other, on a great circle of the terrestrial sphere (which supposition implies that the ship's course is altered every instant), then the one angle found by this problem will be the course with which the ship left the one place, and the other angle the course with which she arrived at the other place. The arc of the great circle intercepted between the places would be the distance sailed.

Prob. 16. To construct a horizontal dial by the globe for a given latitude.

Rectify the globe for the latitude; bring the first meridian under the brazen meridian, and note the arcs of the horizon intercepted between the southern point and the several meridians in the eastern and western hemispheres. If the number of meridians drawn on the globe be twenty-four, which is usually the case, the arcs intercepted on the horizon will measure the angles which the hour-lines make with the meridian. To find the angles corresponding to half-hours and quarters, turn the globe gradually from its position in which the first meridian was under the brazen meridian, noting for each arc of 3° 15′ of the equator that passes under the brazen meridian, the arc of the horizon intercepted between the southern point and the first meridian; the arcs thus found give the positions of the lines corresponding to the half-hours and quarters. The style of the dial represents the axis of the earth, and must therefore make with the plane of the horizon an angle equal to the latitude of the place.

A direct north or south dial for any latitude may be constructed in the same manner, by considering it as a horizontal dial for a latitude which is the complement of the given latitude.

II. *Solution of Problems by the Celestial Globe.*

Prob. 1. To find the latitude and longitude of any star.

Bring the pole of the ecliptic to the meridian. Then having fixed the quadrant of altitude over the pole, place it over the given star; the number of degrees between the ecliptic and the given star is the latitude; and the number of degrees on the ecliptic between the edge of the quadrant and the first point of Aries indicates the longitude.

Prob. 2. To find a star's place in the heavens, its latitude and longitude being given.

Place the extremity of the quadrant of altitude on the pole of the ecliptic, and make its graduated edge cut the ecliptic in the longitude of the star; then the star will be found under the degree of the quadrant that denotes its latitude.

Prob. 3. To find the right ascension and declination of the sun or of a star

Bring the sun's place, or the star, to the meridian; the degree of the equator cut by the meridian gives the right ascension, and the degree of the meridian over the sun's place, or the star, shows the declination north or south.

Prob. 4. The latitude of a place, the day and hour being given, to arrange the celestial globe so as to exhibit the appearance of the heavens at that place and time.

Rectify the globe for the latitude of the place; bring the sun's place for the given day to the meridian; set the index to XII.; then turn the globe till the index point to the given hour. In this position, the globe will represent the actual appearance of the heavens.

Prob. 5. To find the time when any of the heavenly bodies rises, sets, or comes to the meridian, on a particular day at a given place.

Rectify the globe for the latitude of the place; bring the sun's place to the meridian, and set the index to XII.; then turn the globe till the star comes to the eastern edge of the horizon; the index will show the time of rising. Next, turn the globe till the given star comes to the western edge of the horizon; the index will show the time of setting. Lastly, bring it to the meridian, and the index will show the time of its culmination or southing.

Prob. 6. To find on what day of the year any given star comes to the meridian at a given hour.

Bring the given star to the meridian, and set the index to the given hour; turn the globe till the index points to XII. noon, and note the degree of the ecliptic cut by the meridian; the day of the month which corresponds to that degree is the day required.

Prob. 7. The latitude of a place, the altitude of a star, and the day of the month, being given; to find the hour of the night.

Rectify the globe for the latitude; bring the sun's place to the meridian, and set the index to XII.; fix the quadrant in the zenith, then move the globe and the quadrant till the star comes under the degree of the quadrant which denotes the given altitude, and the index will show the hour required.

Prob. 8. The year and day being given, to find the place of a planet.

Find the sun's place for the given day, and bring it to the meridian; set the index to XII.; then find in the Nautical Almanac for the year the time when the planet passes the meridian on the given day, and turn the globe till the index points to the hour thus found; find in the almanac the declination of the planet for the same day, and under it on the globe is the place of the planet.

These are a few of the more important problems that can be resolved by the globes, and will be sufficient to illustrate the principle of solution. The solution of problems by the armillary sphere depends upon the very same principles.

CHAP. IV.—OF THE CONSTRUCTION AND USE OF MAPS.

In representing the geographical divisions of the earth's surface, two objects are to be kept in view; on the one hand, to exhibit accurately to the eye the relative position of the different countries; and on the other hand, to give a delineation sufficiently minute to furnish a distinct knowledge of the necessary details. As a globe has very nearly the exact figure of the earth, the representation which it affords of the surface fulfils the first of these objects in the most perfect manner; but to attain the second it would be requisite to enlarge the globe beyond all convenient size. A globe of the ordinary dimensions serves almost no other purpose in this respect, but to convey a clear conception of the earth's surface as a whole; exhibiting the figure, extent, position, and general features of the great continents and islands, with the intervening oceans and seas. To obtain a detailed representation of any part of the earth's surface, geographers have therefore found it necessary to have recourse to *Maps*, in which countries are delineated on a plane, while the mutual proportions of the distances of places are preserved as nearly as possible the same as on the globe.

For the construction of maps different mathematical hypotheses have been adopted.

By one method of construction, that of *projection*, the boundaries of countries, and their more remarkable features, are represented according to the rules of perspective, on the supposition of the eye being placed on some point of the sphere, or at some given distance from it, which may be increased indefinitely. Wherever the eye is supposed to be situated, the representation thus obtained answers very well, provided the surface to be represented is of small extent, and the point of view, or *projecting point*, is nearly over the centre; but when the surface is of great extent, for example, a whole hemisphere, those places which are situated near the border of the projection are in all of them much distorted.

Another method, that of *development*, is founded on the supposition that the spherical surface to be represented is a portion of a cone, of which the vertex is situated somewhere in the polar axis produced, and the conical surface is supposed either to touch the sphere in the middle parallel of the map, or to fall within the sphere at the middle parallel, and without it at the extreme parallels. The surface of the cone is then supposed to be spread out into a plane.

A third method, which depends on the development of a cylindrical surface, is that according to which maps are so delineated as to have the parallels of latitude and circles of longitude respectively represented by parallel straight lines. By this method marine charts are constructed. As the rhumb makes equal angles with every meridian, it necessarily, according to this method of delineation, becomes a straight line. Such a representation of the earth's surface is commonly called *Mercator's Chart*, although the invention is due to an English mathematician, Edward Wright.

These are the three principal methods employed to represent to the eye the several countries on the surface of the earth.

I. *Construction of Maps by Projection.*

The representation of any portion of the earth's surface obtained by projection, varies, of course, its character according to the several situations of the eye and of the plane of projection, in relation to the meridians, parallels, and various points or places so represented. It is usual to assume the plane of a great circle of the sphere as the plane of projection, and to suppose the eye situated at some point in a straight line perpendicular to this plane, and passing through the centre of the circle. If the distance of the eye from the plane of projection be supposed indefinitely great, the projection is called the *orthographic;* if it is supposed to be upon the surface of the sphere, the projection is called the *stereographic;* and if the eye is supposed to be in such a position that the projections of the meridians and parallels of latitude are nearly equidistant, as the meridians and parallels themselves are upon the globe, the projection is called the *globular.* In order to apply these projections to the construction of maps, we must attend to the properties of each.

1. *Orthographic Projection of the Sphere.*

The fundamental principle in this projection is, that the representation of any point on the sphere is where a perpendicular from that point meets the plane of projection. Hence it follows that the projection of a line of any kind is determined by supposing perpendiculars to fall from every point in that line upon the plane of projection, and a line to pass through the points of intersection of these perpendiculars with that plane.

If the proposed line be a straight line, its orthographic projection will also be a straight line, being the intersection of the plane of projection with the plane perpendicular to it passing through the proposed line.

If the proposed line be the circumference of a circle parallel to the plane of projection, its orthographic projection will also be a circle of the same diameter; since the circle and its projection are the equal and parallel extremities of the cylinder formed by the perpendiculars falling upon the plane of projection.

If the proposed line be the circumference of a circle, of which the plane is perpendicular to the plane of projection, its orthographic projection will be a straight line equal to its diameter.

If the proposed line be the circumference of a circle, of which the plane is neither parallel nor perpendicular to the plane of projection, its projection will be an ellipse, being the curve in which the plane of projection intersects the cylinder formed by the perpendiculars falling upon it from every point in the circumference of the circle.

An accurate idea of the orthographic projection of any line or figure may be obtained by holding it up in the light of the sun, and observing the shadow formed on a plane perpendicular to the direction of the sun's rays. The rays which pass close to the figure are the perpendiculars to the plane of projection, and the shadow is the orthographic projection of the figure.

From the nature of this projection, the orthographic representation of half the surface of the globe shows nearly the true figure and proportions of countries about the middle of the map, that is, directly opposite to the supposed position of the eye; but towards the extremities the true figure and position of the countries are imperfectly exhibited. For this reason this method of projection is seldom employed in geography, but in astronomy it is frequently used. We shall give, however, the orthographic projection of the sphere on the plane of the equator and on the plane of the meridian.

To project the Sphere orthographically on the Plane of the Equator. From any point C as a centre, with any radius CA, describe the circle ABD. Let this circle represent the equator, upon the plane of which it is required to project the sphere orthographically. It is evident that the centre C will be the projection of the poles of the equator, and that since the planes of the meridian circles are perpendicular to the plane of the equator, these circles will be projected into diameters, making with each other the same angles as do the planes of the meridians. Let A 90, B 180, be two perpendicular diameters; they will represent two meridian circles at right angles to each other: divide the semicircle B 90 D into twelve equal parts at the points 15, 30, 45, &c., and let diameters be drawn through the points of division; then the twenty-four radii CB, C 15, C 30, &c. will be the projections of the twenty-four meridians usually drawn upon the globe, any one of which, as BC, may be considered as the first meridian.

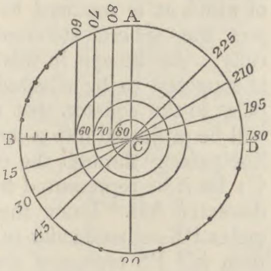

Fig. 11.

Next, it is evident that the parallels of latitude will be projected into circles, which have C for their common centre, and of each of which the radius will be equal to that of the corresponding parallel of latitude, or to the cosine of the latitude of the parallel. Let us suppose that a parallel is drawn on the globe for every tenth degree of latitude; then divide the quadrant AB into nine equal parts, at the points 80, 70, 60, &c.; from these points of division let fall perpendiculars upon BC, meeting it in the points 80, 70, 60, &c.; the lines C 80, C 70, C 60, &c. are equal to the cosines of the arcs B 80, B 70, B 60, &c. to the radius BC. From the centre C, therefore, describe circles with these lines as radii; and these circles will be the projections of the parallels corresponding to the 80th, 70th, 60th, &c. degrees of latitude.

Lastly, the projections of the polar circles and of the tropics may be found by setting off from the point A towards B, and from the point B towards A, twenty-three and a half degrees, drawing perpendiculars to BC through these points of division, and describing circles from C as a centre through the points in which these perpendiculars cut BC.

Thus will the projection of the sphere upon the plane of the equator be completed. The representation given of the polar regions in a map of this description is tolerably correct, but the countries towards the equator are very much distorted.

To project the Sphere orthographically on the Plane of the Meridian. From any point C as a centre, with any distance CA, describe a circle PASB, to represent the meridian circle, on the plane of which it is required to project the sphere orthographically. Draw the diameters PS and AB at right angles to each other: then may PS be assumed as the projection of the meridian which is at right angles to the plane of projection; and AB will be the projection of the equator, since that circle cuts all the meridians at right angles. The other meridians cutting the projecting plane obliquely are projected into ellipses, having PS for their common transverse axis, and the cosines of their inclinations to the projecting plane for their several semiconjugate axes. Let the quadrant AS be therefore divided into six equal parts in the points 15, 30, &c. from which let $15m$, $30n$, &c. be drawn perpendicular to AC, and meeting it in m, n, &c. Describe the ellipses PmS, PnS, &c. having a common transverse axis PS, and Cm, Cn, &c. for their semiconjugate axes: these ellipses are the projections of the meridians passing through every fifteenth degree of the equator.

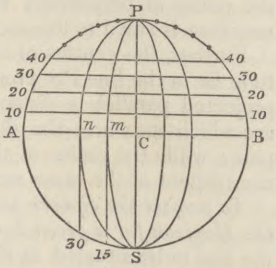

Fig. 12.

Again, to project the parallels of latitude: Divide either of the quadrants AP or BP into nine equal parts, in the points 10, 20, 30, &c. and draw through the points of division straight lines parallel to AB, the projection of the equator: these lines are the projections of the parallels on the one side of the equator to every tenth degree of latitude. The parallels on the other side of the equator are to be drawn in the same manner; as are also the tropics and polar circles, the former at 23½° on each side of the equator. and the latter at 23½° from the poles.

In this projection there is great distortion in the appearance of the regions about the poles, and of all the countries near the meridian PASB. It is as we approach the centre of the map that this distortion begins so far to disappear as to allow a projected portion of the earth's surface to acquire any considerable resemblance to its delineation on the globe.

2. *Stereographic Projection of the Sphere.*

In the stereographic projection of the sphere the eye is supposed to be situated at one of the points where the surface of the sphere is intersected by a straight line passing through the centre, and perpendicular to the plane on which the projection is to be made. This plane, as we have already remarked, is that of a great circle of the sphere; so that the point on the sphere at which the eye is supposed situated will be everywhere 90° distant from the circumference of that circle whose plane is assumed as the plane of projection. In order that the lines and circles on the sphere may be visible to the eye in this position, it will be necessary to suppose the sphere to be transparent. Let, then, ABEC be a great circle drawn on a sphere of this description, and let it pass through the eye at E. Let FG be a plane passing through a, the centre of the sphere, in such a manner as to cut the plane of the circle ABEC at right angles in the diameter HK, and to make each of the arcs EH, EK, equal to 90°: then FG will be the plane of projection. Draw EA the diameter of the sphere passing through the eye; also draw EB, EC, to B and C, any two points in the circumference of the circle ABEC; and let the lines EA, EB, EC, intersect the plane FG in the points a, b, c. By the fundamental principle of the stereographic projection, namely, that the representation of any point is where the straight line drawn from it to the eye intersects the plane of projection, the points a, b, c are the projections of the points A, B, C. It is evident also that the line bc, in which the planes EBC and FG intersect each other, is the projection of the line BC, or of the arc BAC; and that the lines ab, ac, are the projections of the arcs AB, AC.

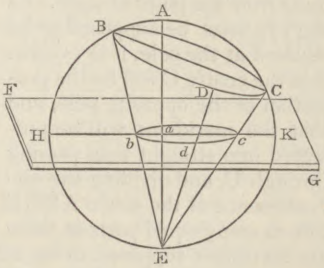

Fig. 13.

Since Eab is a right angle, ab is the tangent of the angle aEb to the radius Ea. But the angle aEb is measured by half the arc AB: hence ab is the tangent of half the arc AB, or the semitangent of AB. Thus it appears, that if a great circle pass through the projecting point E, any arc of it reckoned from the opposite point of the sphere is projected into a straight line passing through the centre, and equal to the semitangent of that arc.

Let BDC be any circle drawn on the sphere, and having BC for a diameter. Take D any point in the circumference of that circle, and draw ED intersecting the plane FG in the point *d*. If the point D be carried round the circumference BDC, the line ED will trace the surface of a cone of which BDC is the base; and the line *bdc* (the intersection of the plane FG with the conical surface), which is traced by the point *d*, is the projection of the circle BDC.

Now, it can be demonstrated that the angles EBC, ECB, are equal to E*cb*, E*bc*, each to each; so that the cones EBC, E*bc* are similar. Hence the projection *bdc* is a circle, whose diameter *bc* is found by taking *ab* and *ac* equal to the semitangents of the arcs AB, AC.

Thus it appears that every circle of the sphere is, according to the stereographic projection, represented by a circle; but a circle can be described when three points in the circumference are given, or when two points in the circumference and the radius are given. Hence this property renders the projection of the sphere by this method very easy.

Another very elegant and important geometrical property of this projection is, that any two straight lines touching the sphere at one and the same point are represented by two straight lines which make with each other on the plane of projection an angle equal to that contained by the touching lines themselves. Hence also the angle formed by any two circles of the sphere is equal to the angle formed by their projections.

When it is further considered that the stereographic projection gives a representation of a hemisphere, in which the parts about the extremity of the map are less distorted than in the representation obtained by the orthographic projection, it must be concluded that the former method is preferable to the latter.

To project the Sphere stereographically on the Plane of the Equator. Upon C as a centre describe a circle ABGE to represent the equator, on the plane of which it is required to project the sphere; or rather that hemisphere which lies remote from the point of sight. As the eye must be supposed to be situated at the pole, it is evident that the centre C will be the projection of the opposite pole, and that the meridians will be projected into straight lines passing through C, and dividing the circumference of the circle ABGE into as many equal parts as there are meridians supposed to be drawn on the globe. If there are twenty-four meridians, then draw AG any diameter, and divide the semicircle AEG into twelve equal parts. Through the points of division draw diameters, as BCE FCK, DCH, &c., and the radii thus found will be the projections of the meridians corresponding to every fifteenth degree of the equator, any one of which may be assumed for the first meridian.

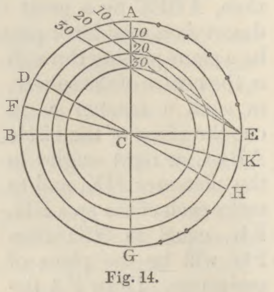

Fig. 14.

Again, to project the parallels of latitude; let AG and BE be perpendicular diameters. Divide the quadrant AB into nine equal parts in the points 10, 20, 30, &c. From E to the several points of division draw straight lines intersecting AC in the points 10, 20, 30, &c. The lines C10, C20, C30, &c. are the semitangents of the distances of the several parallels of latitude from the pole. Hence the points 10, 20, 30, &c. are the points of intersection of the projected parallels with the projected meridian AG. Upon C, then, as a centre, at the distances C10, C20, C30, &c. describe concentric circles, and these will be the projections of the parallels corresponding to every tenth degree of latitude. The tropics and polar circles are found in the same manner.

To project the Sphere stereographically on the Plane of a Meridian. From the centre C, with any radius CA, describe the circle ASBP to represent the meridian on the plane of which it is required to project the sphere stereographically. As the eye, in this case, is supposed to be situated at a point in the equator, that circle will be projected into a straight line passing through the centre C; let it be represented by the diameter AB. Draw the diameter PS perpendicular to AB; then will PS represent the meridian passing through the eye, and P and S will be the poles. To project the other meridians, divide the quadrant AP into nine equal parts (supposing a meridian to pass through every tenth degree of the equator) at the points 10, 20, 30, &c., and from S draw straight lines to these points of division intersecting AC in the points 10, 20, 30, &c. The lines C10, C20, C30, &c., are the semitangents of the arcs of the equator which measure the distances of the points in which the several meridians cut the equator from the point of the sphere opposite to the eye. Hence the points 10, 20, 30, &c., are the points in which the projected meridians will intersect the projected equator AB. But the projected meridians also pass through the points P and S. In each, therefore, there are three points given. If we describe, then, the arcs P10S, P20S, P30S, &c., these arcs will be the projections of the meridians on one side of that passing through the point opposite to the projecting point, and those on the other side are to be found in like manner.

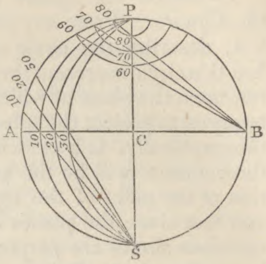

Fig. 15.

Again, by dividing each of the quadrants PA, PB into nine equal parts, we find two points in each of the parallels of latitude. A third point in each will be found by drawing straight lines from B to each of the points of division 80, 70, 60, &c. so as to intersect PC in the points 80, 70, 60, &c.; for the lines C80, C70, C60, &c. are the semitangents of the arcs intercepted upon that meridian of which PS is the projection between the several parallels and the point of the sphere opposite to the projecting point. Describe, then, the several arcs through the three points found in each: and in this manner the parallels on one side of the equator are found. Proceed in the same manner with regard to the parallels on the other side of the equator, and with regard to the tropics and polar circles, and the projection will be completed.

It is evident that the centres of all the projected meridians will lie in the line AB, or in that line produced; and from the construction it is easy to show that the distance of the centre of each projected meridian from the point C is equal to the tangent of the inclination of the meridian to the plane of projection; while the radius of the projected meridian is equal to the secant of the same angle.

Further, the centres of all the projected parallels of latitude lie in the line PS produced; and the centre of each projected parallel is distant from C by the secant of the arc which measures the distance of the parallel from the pole; while the radius of the projected parallel is equal to the tangent of the same arc.

To project the Sphere stereographically on the Plane of the Horizon for a given Latitude. We must here suppose the eye to be situated at the point of the sphere opposite to the place of which the latitude is given. From the centre C, with any radius CN, describe a circle NWSE to represent the horizon upon which it is required to project the sphere. To avoid intricacy among the lines necessary to be drawn for the construction, let the subsidiary circle N′W′S′E′ be described with the same radius. Through C, the centre of the former circle, and C′, the centre of the latter, draw two diameters WE, NS, and W′E′, N′S′, intersecting each other at right angles. Let the diameters NS, WE be the projections of the meridian of the given place, and of a semicircle at right angles to that meridian, and passing also through the given place. It is evident that the points N, W, S, E are the four cardinal points of the horizon. On the circumference of the subsidiary circle N′W′S′E′ take N′P′ equal to the given latitude; and draw the straight line W′P′ intersecting CN′ in P″: then will C′P″ be the semitangent of the distance of the pole from the point on the sphere opposite to the projecting point. Make therefore CP equal to C′P″, and the point P is the projection of the pole. Draw the diameters P′*p*, FA′ at right angles to each other; then will E′A′ be equal to the latitude; and by drawing W′A′ to intersect C′S′ in A″, we obtain C′A″ the semitangent of the distance of the point in which the equator intersects the meridian from the point of the sphere opposite to the projecting point. Make CA equal to C′A″; and through the three points W, A, E, describe an arc of a circle; the arc WAE will be the projection of the equator. Next, we shall show the manner of drawing the parallels of latitude, by taking as an example the two parallels which are twenty and forty degrees distant from the pole. In the subsidiary circle take P′20 and P′40, equal to 20° and 40° on each side of P′. Draw from W′ to the points thus found straight lines intersecting C′N′ and C′S′ in the points *a*′, *b*′, and *c*′, *d*′. The lines *a*′*b*′ and *c*′*d*′ are the diameters of the projected parallels corresponding to 50° and 70° of latitude. Make C*a*, C*b*, C*c*, C*d*, equal C′*a*′, C′*b*′, C′*c*′, C′*d*′ respectively, and upon *ab* and *cd* as diameters describe circles; these circles are the projections of the parallels required. In the same manner are the other parallels of latitude, the tropics, and the polar circles to be drawn.

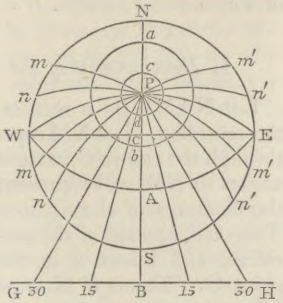

Fig. 16.

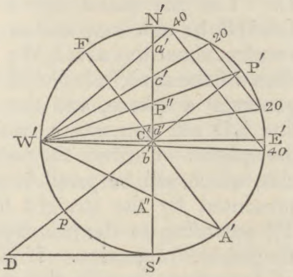

Fig. 17.

Again, to project the meridians;—the straight lines NP, PS, are the projections of the opposite meridians which pass through the north and south points of the horizon. The meridian circle, which is at right angles to that represented by NS, passes through the east and west points of the horizon, so that three points in its projection are given, namely, the points W, P, E; its projection may therefore be drawn. But it may be more conveniently found by considering that the meridian in question makes with the plane of projection an angle equal to the given latitude; the centre of its projection, which is in CS produced, must therefore be distant from the point C by the tangent of the given latitude, and its radius will be equal to the secant of the same. From the point S′ draw S′D, touching the circle in S′, and meeting P′*p* produced in D; then DS′ and DC′ are the tangent and secant of the given latitude. In CS produced take CB equal to DS′; and on B as a centre describe an arc through the point P, which will also pass through W and E. The arcs PW, PE will represent the opposite meridians, which are at right angles to the meridian of the place for which the projection is made. With regard to the other meridians, it is not difficult to see that their centres will lie in a straight line GH drawn through B at right angles to CB; and that the distance of the centre of each projection from the point B will be equal to the tangent of the inclination of the corresponding meridian circle to that meridian circle which passes through the east and west points; while the radius of the projection will be equal to the secant of the same inclination. Let us suppose, then, that the meridians are to make with each other angles each equal to 15°; at the point P make the angles B P 15, B P 30, &c. equal to 15°, 30°, &c. respectively, and let P 15, P 30, &c. meet the line GH in the points 15, 30, &c. Upon these points, as centres, describe through the point P the arcs *m*P*m*′, *n*P*n*′, &c.; then will P*m*, P*n*, &c. P*m*′, P*n*′, &c. be the projected meridians required. In this manner the projection may be completed.

3. *Globular Projection of the Sphere.*

In the globular projection of the sphere a point is assumed for the position of the eye, at a finite distance from the centre greater than the radius, and so situated that the degrees in the representation shall be nearly equal to each other, and the deviations from equality in the representations of equal portions of the spherical surface thus in some measure corrected. To determine the position of the point of view so as to answer these conditions, let ADBF be a section of the sphere made by a plane passing through C the centre, and through the point E which is assumed as the projecting point required. Through C draw EB, meeting the circumference ADBF in A and B, and draw the diameter DF at right angles to EB. Bisect the quadrant DB in I, and draw EI meeting DC in G; the point G will be the projection of the point I. But by hypothesis the projections of equal arcs are nearly equal; let then DG be assumed equal to GC. Join DB, and draw CI meeting DB in H. Join GH, and draw IK parallel to DC, or at right angles to AB. Then it is evident that DH is equal to HB; and therefore DH : HB : : DG : GC. Hence the line GH is parallel to CB; and we have IH : HC : : (IG : GE : :) KC : CE. But IH is equal to BK, and HC to KC : therefore BK : KC : : KC : CE, and we have $BK \cdot CE = KC^2 = IK^2 = BK \cdot KA$. Hence CE is equal to KA; and taking away the common part AC, there remains EA equal to KC or to IK; that is, EA, the distance of the point of view above the surface, is equal to the sine of 45°. If the radius CA be divided into 100 equal parts, EA is therefore nearly equal to 71 of these parts.

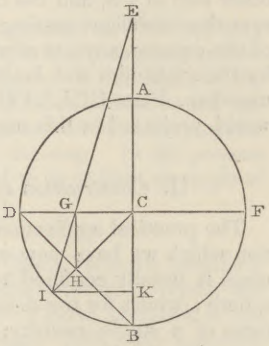

Fig. 18.

This projection was first suggested by M. Delahire, and the approximation which it gives to equality in the projection of equal arcs of a circle perpendicular to the plane of projection is considerable. The circles of the sphere are, according to this method of projection, represented by ellipses. An approximation to this method is, however, generally all that is aimed at. The circles of the sphere are represented by circles; and, without any regard to the distance of a projecting point, the degrees of longitude on the equator and of latitude on the meridian are made all equal to one another; the plane of the meridian being assumed as the projecting plane. The following is the construction by which such a representation of a hemisphere of the earth's surface is obtained.

From the centre C (fig. 19), with any radius CA, describe a circle PASB to represent the meridian on which it is required to project the hemisphere. Draw the diameters AB, PS, at right angles to each other; and let PS represent the meridian of which the plane is at right angles to the plane of projection : then AB will be the projection of the equator, and the points P and S the projections of the poles.

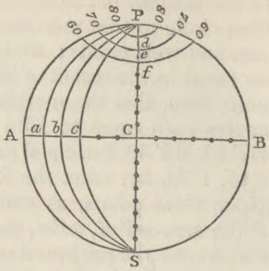

Fig. 19.

To project the parallels on the north side of the equator, divide each of the quadrants PA, PB, into nine equal parts: also divide the radius CP into the same number of equal parts. Let 80, 70, 60, &c. *d*, *e*, *f*, &c. be the points of division : the parallel corresponding to 80° of latitude will pass through the three points 80, *d*, 80 ; that corresponding to 70° of latitude through the three points 70, *e*, 70, and so on. Describe circles, accordingly, through these points, and the parallels on the north side of the equator will be drawn. In the same manner are the parallels on the south side of the equator to be projected, as are also the tropics and polar circles.

Again, to project the meridians, divide the radius AC into six equal parts in the points *a*, *b*, *c*, &c. and through the points P and S, and these points of division, describe circles P*a*S, P*b*S, &c. Proceed in the same manner on the other side of PS, and the circles thus described will represent the meridians passing through every fifteenth degree of the equator, any one of which may, in laying down places by their latitudes and longitudes, be assumed for the first meridian. Plate CCLXVIII. is a planisphere, or map of the world, projected in this manner.

II. *Construction of Maps by Development.*

The practical application of the three methods of projection which we have now explained, to the construction of maps is usually confined to the representation of a hemisphere ; whilst for the delineation of the geographical features of a single country, the method of development is commonly employed. The particular purpose for which a map is to be used may make it more or less important that it should exhibit, with all the precision that can be attained, some particular features of the country represented. The purposes of civil government require maps that give the true figure and dimensions of territory. For military affairs, maps that give correct distances are chiefly useful ; whilst for the purposes of the navigator, the bearings of places, one from another, must be correctly, and, at the same time, simply exhibited. The first two objects are nearly gained in ordinary maps. But, for the attainment of the last, a map of a peculiar construction, called *Mercator's Chart*, has been invented ; which, while it answers completely the purpose of the navigator, is not immediately applicable to any other.

It is an obvious property of a cone and of a cylinder, that the surface of each admits of being spread out on a plane. If a cone be laid with its slant side on a plane, the former will coincide with the latter along a line stretching from the point of contact in the base to the apex of the cone. Hence, if the cone is rolled round, whilst the apex continues at the same point, every point upon the surface of the cone will come in contact with a corresponding point in the plane surface ; so that a sector of a circle will be described, with which the surface of the cone, if expanded, would exactly coincide. A cylinder admits of being rolled along a plane surface in a similar manner. But this is not the case with respect to a sphere. For since a sphere touches a plane only in a point, if the former be rolled along the latter in one direction, the successive points of contact will mark out a straight line. A narrow zone of the sphere may, however, be supposed, without great error, to coincide with the surface of a cone or cylinder ; and this hypothesis gives rise to a twofold construction by development, that by the development of a conical surface, and that by the development of a cylindrical surface.

1. *Development of the Curve Surface of a Cone.*

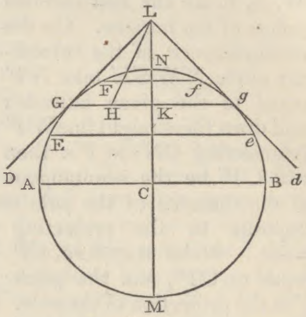

Fig. 20.

Let NAMB be a section of the sphere by the plane of the meridian. Let NM represent the axis ; then AB drawn through the centre C, at right angles to NM, will represent the diameter of the equator. Take EF, any arc of the meridian, and bisect it in the point G. Through G draw LD a tangent to the circle NAMB, and meeting the axis MN produced in the point L. Let the plane figure LGMB be now supposed to revolve about the axis LM ; then will the semicircle NAM generate a sphere, and the line LD will generate a conical surface, which will touch the sphere. Further, the points E, G, F will describe circles, which will be parallels of latitude represented by the straight lines E*e*, G*g*, F*f*, according to the principles of the orthographic projection. If EF be an arc of not many degrees, the zone comprised between the parallel circles E*e*, F*f* will nearly coincide with the corresponding portion of the conical surface intercepted between the planes of the same circles. Take any point H in the circumference of the circle described by G, the middle point of the arc EF, and join LH.

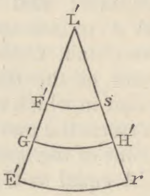

Fig. 21.

Let us now suppose the conical surface comprehended between the straight lines LG, LH, and the arc GH, to be spread out into a plane L′G′H′. Then it is evident that the arc GH on the middle parallel, of which the radius is the cosine of the middle latitude, is changed into an arc G′H′ of which the radius is L′G′ = LG the cotangent of the middle latitude. In the line L′G′, and in L′G′ produced, take G′F′, G′E′ equal to the arc EG or GF. Then, on the point L′ as a centre, at the distances L′E′, L′F′ describe the arcs E′*r*, F′*s*, and the plane surface E′F′*sr* may be considered as nearly equal to the spherical surface comprehended between the meridians passing through G and H, and the arcs of the parallels E*e*, F*f* intercepted by these meridians. Hence, if any tract of country situated on the corresponding portion of the earth's surface be delineated on the plane E′F′*sr*, the representation of it thus obtained will bear a near resemblance to its delineation on the globe, the resemblance increasing according as the zone comprehended between the extreme parallels is diminished in breadth.

Such is the principle of the conical development. Let us now consider how the line L′G′ and the angle G′L′H′ are to be determined, so as to suit the space E′F′*sr* to any given difference of longitude and given middle latitude ; also in what manner the parallels of latitude and the meridians are to be drawn on that surface.

We have already seen, that L′G′ is equal to the cotangent of the middle latitude to the radius of the sphere. If the radius of the sphere be considered equal to unity, the trigonometrical tables will give the length of L′G′ in parts of the radius. But it will be more convenient to have it expressed in minutes of a degree. Now, since the semicircumference is to radius as 3·1416 is to 1, if we put R for radius, we have $3{\cdot}1416 : 1 :: 180 \times 60 : R = 3437{\cdot}7$, which is the radius expressed in minutes of a degree. Hence L′G′ expressed in the same manner will be equal to

$$3437{\cdot}7 \times \text{cotan. middle latitude.}$$

Again, since the arc GH is equal in length to the arc G′H′ by hypothesis, the angle at K measured by the former, must be to G′L′H′ measured by the latter, as the radius L′G′ is to the radius GK; that is, if we put D for the difference of longitude, and ϕ for the angle G′L′H′, we will have D : ϕ : : (L′G′ : GK : : cot. mid. lat. : cos. mid. lat. : :) rad. : sine mid. lat. Hence we obtain

$$\phi = D \times \text{sine mid. lat.}$$

The angle L′ being thus determined, and the lines L′G′, G′E′, G′F′ being known, and expressed in minutes of a degree, we can describe the figure E′F′*sr*, so that it shall be accommodated to any given middle latitude and given difference of longitude. Then having divided E′F′ into as many equal parts as there are minutes in the difference of latitude, or as there are some given number of minutes in it, the points must be ascertained through which the parallels intended to be drawn pass, and from L′ their common centre, these parallels are to be drawn accordingly. The parallels E′*r*, F′*s* are in like manner to be divided each into as many equal parts as there are minutes, or some given number of minutes, in the difference of longitude: and points being ascertained in each of these parallels through which the meridians proposed to be drawn pass, the straight lines joining the corresponding points are the meridians required. It is by this method that common maps of particular countries are constructed.

As an example, let it be required to construct a map of Great Britain and Ireland, which must extend from 50° of latitude to about 61° north, and from 2° east to about 11° west longitude.

To find L′G′, L′E′, L′F′.

61° 61°
50° 50°
2)111 2)11 = diff. of lat. = 660′
55° 30′ = mid. lat. 5° 30′ = 330′ = G′E′ or G′F′.

Log. cot. mid. lat., 55° 30′, 9·8371343
3437·7......... log. 3·5362680
L′G′ = 2362′·7........ log. 3·3734023
G′E′ or G′F′ = 330′·0
L′E′ = 2692′·7
L′F′ = 2032′·7

To find the angle G′L′H′.

Log. sine mid. lat. 55° 30′............ 9·9159937
Diff. of long. = 13° = 780′......log. 2·8920946
Angle G′L′H′ = 643′ = 10° 43′....log. 2·8080883

To find the chords of the arcs E′*r*, F′*s*.

Chord of arc E′*r* = {2L′E′...............log. 3·7312180
{× sin. ½ L′........... 8·9695999
Chord of arc E′*r* = 502′·1..........log. 2·7008179
Chord of arc F′*s* = {2 L′F′ ....log. 3·6091033
{× sin. ½ L′............... 8·9695999
Chord of arc F′*s* = 379′·1............log. 2·5787032

Having now determined the four sides of the trapezoid formed by the meridians E′F′ and *rs*, and the chords of the arcs E′*r*, F′*s*, it is easy to describe that trapezoid, the length of the sides being measured on any convenient scale of equal parts, which is to be considered as a scale of minutes of a degree on the meridian. Let it be described accordingly, and let the sides E′F′, *rs*, be produced to meet in a point, which will be the point L′. Then, from that point as a centre describe the arcs E′*r*, F′*s*, and divide these arcs each into thirteen equal parts, since the difference of longitude is 13°. Also, divide E′F′ and *rs* each into eleven equal parts corresponding to the given difference of latitude 11°. Having fixed upon the number of meridians and parallels of latitude that are to be drawn, describe from the point where the lines E′F′, *rs*, intersect when produced, as a centre, the parallels through the proper points of division in E′F′ or *rs*; and draw straight lines joining the proper corresponding points of division in E′*r*, F′*s* for the meridians: we shall here suppose the meridians and parallels to be drawn for every second degree. Number the degrees of latitude and longitude as in the figure, and the map is prepared for having traced upon it the outline of the coasts of the British isles, and places laid down according to their latitudes and longitudes.

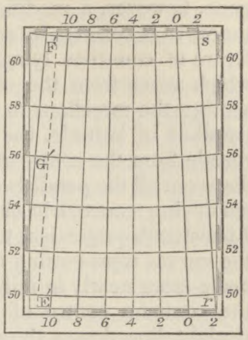

Fig. 22.

It is evident that if the point in which E′F′ and *rs* intersect each other becomes very distant, it may be exceedingly troublesome, or practically impossible, to describe from it as a centre the parallels of latitude. An obvious remedy for this inconvenience is, to join together two rulers, as AB, AC, at the point A, in such a manner as that they may contain an angle equal to the angle in the segment which has for its arc the parallel to be drawn. If the edges of the rulers be made, by means of two pins, to slide over the extremities D, E of the parallel, a pencil fixed at the angular point A will trace the parallel on the map. In the present instance the rulers must be placed so as to form an angle of

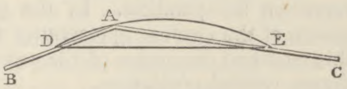

Fig. 23.

$$\left(\frac{360° - 10° 43'}{2} = \right) 174° 38' 30''.$$

The conical development has been variously modified, so as to remove as much as possible its defects. Thus, one modification was given by the Rev. Patrick Murdoch in the *London Philosophical Transactions*, 1758. He supposed the cone to pass through points of the meridian between the middle latitude and the extremities of the arc to be projected, its side being parallel to the tangent at the middle latitude, while the points where the cone intersects the meridian are so situated as that the conic surface is exactly equal to the spherical surface which it represents. Let M denote the arc of the meridian to be represented in the map; then, according to this method of development, L′G′, the radius of the middle parallel on the map, is equal to

$$\frac{\text{chord of arc M}}{\text{arc M}} \times \text{cot. mid. lat.}$$

the cotangent being supposed to be expressed in parts of the radius of the sphere. In other respects the construction is the same as in the ordinary conical projection.

But the simplest and most successful method of remedying the defects of the conical development is that known by the name of *Flamsteed's projection.* The English astronomer by whom this method was invented, and whose name it bears, made use of it in constructing his celestial atlas. He developed all the parallels of latitude on the sphere into straight lines, and also one of the meridians, namely, that which passes through the middle of the chart. To this meridian the lines representing the parallels are perpendicular, and the length of each is the same with that of the parallel on the sphere which it represents. Dividing the parallels in the projection into equal parts, in like manner as the parallels on the sphere are divided, he supposed curved lines to be drawn through the corresponding points of division, and these curve lines represent the meridians. Flamsteed employed this projection in representing the position of the stars; but it is also made use of in geography, particularly for the delineation of countries which extend on both sides of the equator.

Mathematical Geography.

Mathematical Geography.

To suit it more effectually to this purpose, it has undergone, however, a modification of very considerable importance, as it corrects in some measure the distortion in the figure of countries lying near the extremities of the map, which arises from the obliquity of the curve lines representing the meridians to the straight lines representing the parallels of latitude, the obliquity increasing as the former recede from the centre of the map. On the globe the meridians cut all the parallels of latitude at right angles; and by employing concentric circles instead of straight lines, as in Flamsteed's projection, to represent the parallels of latitude, the curves representing the meridians on the map may be made more nearly to fulfil this condition. For this purpose the common centre of the circles, which is situated in a straight line drawn through the middle of the map as an axis, is so assumed that the radius of the middle parallel of latitude is equal to the cotangent of the middle latitude; an assumption which diminishes as much as possible the obliquity of the angles made at the intersections of the curves which represent the meridians, with the circles which represent the parallels. In the position of the common centre of the circles representing the parallels of latitude, this modified projection of Flamsteed coincides with the ordinary conical projection.

We shall exemplify this construction by showing how to describe, according to it, the parallels and meridians for a map of Europe.

Let the map be supposed to extend from 35° to 70° north latitude. Hence the middle latitude will be 52° 30′, and the radius of the middle parallel of the map (being equal to 3437′·7 × cot. 52° 30′) will be equal to 2637′·8.

Draw, then, any line LE for the axis of the map; and assuming any point C for the point of intersection of the axis with the parallel of middle latitude, set off the length of the radius of that parallel from C to L, taken from any convenient scale of equal parts, which is to be considered as a scale of minutes of a degree. Thus the point L, the common centre of the circles representing the parallels, is determined.

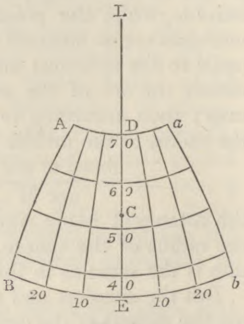

Fig. 24.

Let us now suppose that a parallel is to be drawn through every tenth degree of latitude: that is, through 40°, 50°, 60°, 70°. As the middle latitude exceeds 50° by 150 minutes, take 150′ from the scale of equal parts, and set it off from C to 50. Again, take 600, which are equal to 10°, from the scale of equal parts, and set off that distance from 50 to 40, from 50 to 60, and from 60 to 70. The point E, corresponding to 35°, is found by setting off 300′ from the point 40. If we were to proceed according to Flamsteed's method, as originally employed by him, it would be necessary to draw straight lines through the points E, 40, 50, &c., perpendicular to DE, and therefore parallel to each other, and to make these lines equal respectively to the portions of the parallels on the sphere which they represent; then, dividing each line on both sides of the axis into as many equal parts as are indicated by the number of meridians intended to be drawn on each side of the axis, through the extremities and corresponding points of division to trace curve lines to represent the meridians. In this case the point L would not be required. But in the modification of the method which we are now exemplifying, from the point L as a centre an arc of a circle is to be described through each of the points E, 40, 50, &c. and each of these arcs of longitude is to be made equal to the arc of the parallel on the sphere which it represents. Let us then fix upon some meridian of a given number of degrees of longitude to the eastward and westward of that represented by the line DE, which is to be so drawn as to fulfil this condition. Let AB and *ab* be the meridians assumed, the former 30° to the westward, and the latter 30° to the eastward, of DE.

The arc BE or *b*E is equal in length to an arc of 30° on the parallel of latitude 35°. Now, the latter arc may be determined in geographical miles or minutes of the meridian by means of the table (page 481), showing the length of a degree of longitude for every degree of latitude in geographical miles. Thus, 30° on the parallel of 35° latitude is found equal to 1474′·5. But the arc BE is of the same length. Therefore we have BE or *b*E = 1474′·5.

We might next find the angle which the arc BE subtends at the centre L, and thus determine the points B and *b*. But it is more convenient to find the chord of the arc, which may be easily done as follows:—

Put a for any arc of a circle whose radius is r. Then

$$\text{sin. } a = a - \frac{a^3}{6r^2} \text{ nearly, if the arc is not very great.}$$

In this expression put $\frac{1}{2}a$ instead of a, and it becomes

$$\text{sin. } \tfrac{1}{2}a = \tfrac{1}{2}a - \frac{a^3}{48r^2} \text{ nearly.}$$

Doubling both sides of this equation, and observing that 2 sin. $\frac{1}{2}a$ = chord of a, we obtain

$$\text{chord of } a = a - \frac{a^3}{24r^2} \text{ nearly.}$$

For arcs not exceeding 30°, this formula will give the length of the chord with sufficient exactness. Let us apply it to find the chord of the arc BE.

Here $a = 1474'{\cdot}5$, and $r = \text{LE} = 2637'{\cdot}8$.

$$\begin{array}{rr}
\text{Log. } r = 3{\cdot}421242 & \text{Log. } a = 3{\cdot}168645 \\
2 & 3 \\
\hline
\text{Log. } r^2 = 6{\cdot}842484 & \text{Log. } a^3 = 9{\cdot}505935 \\
\text{Log. } 24 = 1{\cdot}380211 & \text{Log. } 24\,r^2 = 8{\cdot}222695 \\
\hline
\end{array}$$

Log. $24r^2 = 8{\cdot}222695$. Diff. of arc and chord, 19·2, 1·283240

Hence the chord of the arc BE is 1455′·3 of the meridian. Taking this number from the scale of equal parts, and setting it off from E towards B and *b*, the points B and *b* are determined.

Proceeding in the same manner, we may find the arcs of 30° of longitude, with their chords, on the other parallels of latitude; and thence determine the remaining points through which each of the projected meridians AB, *ab* passes. The curves drawn through these points will be the representations of the two meridians which have 30° of longitude to east and west of the meridian represented by DE.

The points in which the projections of the intermediate meridians intersect the projected parallels, may be found by dividing each parallel into thirty equal parts from the axis, both towards the right and left; then, by tracing curves through the proper corresponding points of division, as many meridians may be represented as are judged to be necessary. If the map is to extend farther than 30° on each side of its middle meridian, the division of the parallels may be extended to the necessary distance beyond the meridians AB and *ab*.

It is a consequence of the properties of this projection, that distances on the map may be readily and accurately measured by a scale of equal parts. This scale may be constructed as follows:—

Draw a straight line AB (fig. 25) equal to any assumed number of degrees of latitude. If we assume 35 degrees, AB will be equal to DE. From B draw an indefinite line BC, making with AB any angle. Then, since AB is equal to 35°, or to 2417 English miles nearly, take 2417 from any convenient scale of equal parts and set that distance off from B towards C, making BD equal to 2417. From the same scale of equal parts take 100, or 200, &c. (in the present instance we shall take 500), according to the number of miles which each of the divisions of the scale is intended to represent; and with this distance in the compasses set off from B towards C the divisions B*m*, *mn*, *np*, *pq*; the remaining part *q*D, being only 417, will not again contain it. Join AD; and through the points of division *m*, *n*, *p*, *q*, draw straight lines parallel to AD, and intersecting AB. Each of the divisions of AB thus found will represent 500 miles, with the exception of that adjacent to A, which will correspond to 417 miles. The distance of two places of the map applied to this scale will give the distance in English miles.

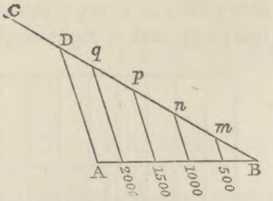

Fig. 25.

2. *Development of the Curve Surface of a Cylinder.*

The principle of this development is analogous to that of the conical, and may be illustrated in a similar manner. Let the arc AB be a fourth part of a meridian, and draw the lines AC, BC to the centre; these lines will be at right angles to each other, so that if we suppose BC to represent the semi-axis of the sphere, then AC will be the radius of the equator. Let EF be any arc of the meridian, and let it be bisected in G. Through G draw DH perpendicular to AC, or parallel to BC. If the plane figure BDGAC be supposed to revolve round BC as an axis, the arc AB will describe one-half of the surface of the sphere, the line DH will describe the surface of a right cylinder, the point A will describe the equator, and the points E, F, G will describe parallels of latitude. If EF be a small arc, the zone of the sphere which it describes will nearly coincide with the corresponding zone of the cylinder. Any tract of country delineated upon the former may, therefore, be nearly represented upon the latter; which being developed, the meridians and parallels of latitude become parallel straight lines, the former at right angles to the latter. Let EF*fe* be a portion of the zone described by EF comprehended between two meridians of which the difference of longitude is equal to the difference of latitude of the parallels described by the points E and F. Since the difference of latitude and difference of longitude are supposed equal, the arc G*g* is the same part of the middle parallel that EF is of the meridian. Hence rad : cos. mid. lat. : : EF : G*g*; so that G*g*, the breadth of the map representing the portion EF*fe* of the spherical surface, may be found in minutes of the meridian. Upon these principles depends the construction of the plane chart, which is said to have been invented by Henry, son of John king of Portugal.

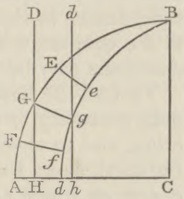

Fig. 26

As an example, let it be required to construct a plane chart extending from 30° to 50° north latitude, and from 5° to 25° west longitude. Here the difference of latitude and difference of longitude are each equal to 20°, and the middle latitude is 40°. Hence we have EF, the length of the chart, equal to 1200′, and the breadth of it equal to 919′·25. Construct a rectangle EF*fe*, of which the sides EF, F*f* are respectively equal to 1200 and 919·25 taken from any the same scale of equal parts, which is to be considered as a scale of minutes of the meridian. Divide EF and F*f* each into four equal parts, and through the points of division draw straight lines parallel to F*f* and EF, and these lines will represent the parallels of latitude and meridians for every fifth degree of latitude and longitude. If the chart is to extend to a greater number of degrees of longitude east or west, the parallels of latitude may be produced, and additional meridians drawn on the left of EF, or on the right of *ef*.

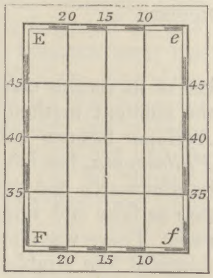

Fig. 27.

In the plane chart the degree of longitude evidently bears to the degree of latitude its proper proportion only at the middle parallel of latitude. Hence the rhumbs, as shown by this chart, are altogether erroneous, except when the places between which the rhumb is drawn are very near the equator.

To serve the purposes of navigation, for which the plane chart was utterly inadequate, the chart was published by Gerard Mercator in 1556 which usually bears his name; but the true principles of its construction were first demonstrated about 1590 by Edward Wright of Caius College, in Cambridge. This chart is constructed on the hypothesis that the globe is expanded so as to meet the interior surface of a cylinder constituted on the equator as its base, and having its axis coincident with that of the globe. The spherical surface is supposed to be stretched in such a manner that at every point the meridian and parallel are lengthened in the same proportion; so that at every point of the chart the ratio of the degree of longitude to the degree of latitude is preserved the same as it is at the corresponding point on the globe. Hence while the meridians become parallel straight lines, and consequently the rhumbs on the developed cylinder are also straight lines, the mutual bearings of places are still correctly shown. The problem of finding the lengthened meridians can be accurately resolved only by the assistance of the fluxional calculus (see FLUXIONS). But we may approximate to the solution by reasoning as follows:—

Let AB be a quadrant of the meridian; draw AC, BC, to the centre; and let BC represent the semi-axis; then AC will be the radius of the equator; and if any point D be taken in the quadrant AB, the arc AD will be the latitude of the point D. Draw AG, CG, the tangent and secant of the arc AD, and DE, DF, its sine and cosine. The increase which the arc AD acquires in being transferred from the sphere to the cylinder is made at every individual point of the arc, so that the whole augmentation is the sum of these indefinitely small increments. Let us suppose, then, that AD is divided into a number of small portions, for example, into minutes. Then if we put L for any latitude, we have rad. : cos. L : : 1′ of the meridian : 1′ on the parallel whose latitude is L. But from the similar triangles GAC, CED, it is evident that CD : CE : : CG : CA : that is, for any latitude L, rad. : cos. L : : sec. L : rad. Therefore we have, sec. L : rad. : : 1′ of the merid. : 1′ on the parallel whose latitude is L; and this applies alike to every minute of which the arc AD is made up. Let us now suppose a minute on any one parallel to become equal to a minute on the equator, or to a minute of the meridian, by the parallel being brought into coincidence with the surface of the cylinder, in consequence of the expansion of the spherical surface. The minute on the meridian undergoes a corresponding increase. Let *d* denote it in its lengthened state; then, taking for granted that the increase on each minute of the meridian depends entirely on that of the higher of the two parallels which pass through its extremities, we obtain

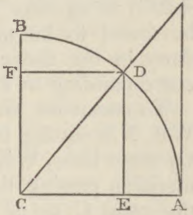

Fig. 28.

$$\text{sec. L} : \text{rad.} : : d : 1' \text{ of equator, or } 1' \text{ of meridian};$$

$$\text{hence } d = \frac{\text{sec. L} \times 1' \text{ of mer.}}{\text{rad.}}$$

Let 1′ of the meridian be now assumed as the radius; then *d* = sec. L to the radius 1′ of the meridian; or, since secants to different radii are proportional to one another, and we only require proportional quantities, we have simply

$$d = \text{sec. L.}$$

Thus the increased minute on the chart for each successive minute of which the arc AD on the sphere is made up, is proportional to the secant of the latitude of the higher of the two parallels which pass through the extremities of that minute. Let *m* denote the number of minutes in the arc AD, and take $\text{L} = 1', 2', 3', \text{\&c.........} m'$ successively; and we obtain for the lengthened meridian corresponding to AD,

$$\text{sec. } 1' + \text{sec. } 2' + \text{sec. } 3' +, \text{\&c.......} + \text{sec. } m'.$$

If we had divided AD into smaller portions than minutes, the approximation would have been so much the nearer to the truth. Upon this principle a table of the lengthened meridians corresponding to every degree and minute of latitude, called a table of *meridional parts*, is calculated; and by means of such a table Mercator's chart is easily constructed. The following table shows the length of the enlarged meridian for every fifth degree of latitude:—

Lat.	Merid. Parts.	Lat.	Merid. Parts.
0°	0·00	50°	3474·47
5	300·38	55	3967·97
10	603·07	60	4527·37
15	910·46	65	5178·81
20	1225·14	70	5965·92
25	1549·99	75	6970·34
30	1888·38	80	8375·20
35	2244·29	85	10764·62
40	2622·69	90	Infinite.
45	3029·94		

The approximate numbers obtained in the manner now pointed out are sufficiently correct for all nautical purposes. From the more rigorous investigation afforded by the fluxional calculus, it is found that the enlarged meridian is proportionally equal to the logarithmic tangent of an arc found by adding to 45° half the arc of latitude reckoned from the equator. Thus, the meridional parts corresponding to 40° of latitude are equal to the logarithmic tangent of $(45° + 20°) = \text{log. tan. } 65° = 33133$; and the meridional parts corresponding to 50° are equal to $\text{log. tan. } (45° + 25°) = \text{log. tan. } 70° = 43389$. These two numbers will be found to be nearly proportional to the numbers set down in the above table as denoting the meridional parts corresponding to 40° and 50° of latitude.

To construct Mercator's chart: Draw two straight lines WE, NS, cutting each other at right angles in the point C. Of these lines, WE is to represent the equator, and NS the meridian passing through the middle of the chart. From the point C set off equal parts on the equator both ways. These divisions are to represent degrees of longitude; and if the size of the chart will admit, each should be subdivided into minutes. Assuming the equator as a scale of minutes, set off from C towards the north and south on the middle meridian the number of minutes in the enlarged meridian, corresponding to each degree of latitude, as shown by a table of meridional parts. Draw straight lines through every fifth or every tenth degree of the equator and divided meridian, and at right angles to them. The lines at right angles to the equator will be the meridians; and those at right angles to the divided meridian, and therefore parallel to the equator, will be parallels of latitude. Any one of the meridians may be assumed as the first meridian.

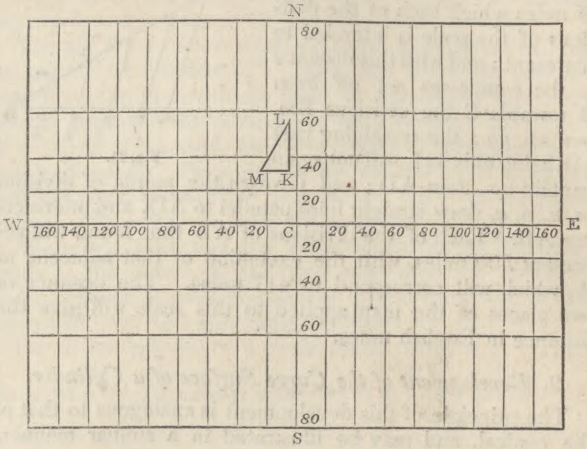

Fig. 29.

To find the bearing of any one place from another, it is only necessary to draw a straight line from the one to the other, and to observe the angle which that line makes with the meridians: that angle is the bearing required, or the *course* on which a ship must be steered in sailing from the one place to the other. Thus, if L be the Lizard Point on the chart, and M the east end of the island of Madeira, join LM, and draw LK parallel to NS, and the angle KLM will be the course to be steered from the Lizard to reach Madeira. The distance of the places may be found by considering that it is the hypotenuse of a right-angled triangle of which the *proper* difference of latitude (not the meridional difference) is one side, and the course the adjacent angle.

Plate CCLXIX. is a chart of the world according to Mercator's projection. The great elongation of the degrees of latitude as we advance northward and southward, renders this projection very defective, in as far as the figure of countries and the relative distances of places are concerned. It answers, however, perfectly the purposes for which it was originally constructed, and has supplied what before its invention was a desideratum in geography.

To complete a map after the circles of latitude and longitude have been projected by any one of the foregoing methods the various objects within the range of the map are to be delineated on it in such a manner as to present to the eye a correct view of the country to be represented. The methods employed to give distinctness and extent to the information conveyed, will be best learned from the actual examination of good maps, both general and particular.

(J. W—E.)

GEOLOGY. See MINERALOGICAL SCIENCE.[1]

GEOMANCY, a kind of divination performed by means of points and lines, originally made by casting pebbles on the ground, and afterwards by marking or pricking dots at random upon paper, and forming therefrom a judgment of futurity, or deciding any question proposed. The dots and lines represented the stars, elements, &c., and hence this pretended science appears to have been a species of astrology. Geomancy was in high repute in Chaucer's time, and continued to flourish down to a late period. Among the last of its serious cultivators appears the name of Oughtred, the eminent mathematician, who died in 1660. Cornelius Agrippa besides some notices in his work, *De Occulta Philosophia*, has left an express tract *De Geomantia;* but he afterwards had the honesty to condemn his own production as false and lying, in his work *De Vanitate Scientiarum.* There was another kind of Geomancy, introduced by Almadul the Arabian, in which conjectures were drawn from rents and fissures in the earth, and which Polydore Virgil conceives to have been invented by the Persian Magi.

---

[1] In consequence of the lamented death of Professor Edward Forbes, who had agreed to contribute this article, it has been found necessary to postpone it.

GEOMETRY.

HISTORY OF THE SCIENCE.

The properties of bodies may be resolved into two classes; one comprehending those which belong to all bodies whatsoever, and another, such as belong only to particular bodies. Amongst the properties of the first class we may consider extension, magnitude, figure, divisibility, impenetrability, inertia, weight, mobility, &c. Some of those of the second are solidity, liquidity, transparency, and the like. Of these properties, *extension*, *magnitude*, *figure*, and *divisibility*, are the subject of Geometry. The discussion of other properties of body belongs to Physics, called also Natural Philosophy.

The objects of geometry having been continually presented to the human mind, and being of such a nature as could at all times be perfectly comprehended, it may be supposed that the science would in some form or other exist from the very beginning of society. Indeed there is a natural geometry which all possess, and which must have been employed in the divisions of property and the erection of dwellings in every age. The name of the science indeed indicates its origin, for it is derived from γεωμετρια, the science of land-measuring.

According to the testimony of Herodotus, the science was first cultivated in Egypt. He had been informed at Memphis and Thebes, that Sesostris the king had divided the lands amongst his subjects, giving to each an allotment, for which an annual tribute was to be paid. The overflowing of the Nile, however, disturbed the landmarks, and rendered it necessary to re-adjust them by measurement; and hence the origin of geometry, which in the course of time passed from Egypt into Greece. There are two things to be here noticed; the assertion of a verification depending on geometry, and the particular opinion of Herodotus as to the origin of the science. If, as some chronologers have supposed, Sesostris be the same as the King Sesac, or Shishac, who made war on Rehoboam, the son of Solomon, it would follow from Herodotus, that geometry had its origin not more than about a thousand years before the Christian era. It might, however, be earlier; for the operation of measuring the land indicated a science which had made some progress. Aristotle has attributed the invention of geometry to the Egyptian priests, who, living secluded from the world, had leisure for study. But however this might be, all ancient writers are agreed in giving the Egyptians the credit of having been the earliest cultivators of geometry.

The philosopher Thales, who lived 640 years before Christ, brought the sciences, and particularly mathematics, into Greece from Egypt, whither he had gone in quest of knowledge at an advanced period of life. Diogenes Laertius relates that he there measured the height of the obelisks by means of their shadows; and Plutarch says, that this display of skill in geometry astonished the king Amasis. This shows that the Egyptians had not then advanced far in geometrical knowledge. Proclus also has recorded that Thales, by geometrical principles, determined the distance of vessels remote from the shore. On his return to Greece he founded the Ionian school, so called from Ionia, his native country. His celebrity for learning excited the attention of his countrymen, and drew to him disciples.

There appears to have been some slight traces of geometry in Greece at a still earlier period. We allude to the geometrical construction of a triangle by Euphorbus of Phrygia, and the discovery of some properties of figures. These, however, were probably just the natural geometry common to all ages. The rule and compasses, most important instruments, have been referred to the ages of fable, the honour of the invention of the latter having been ascribed to the nephew of Dædalus, and that of the square and level to Theodorus of Samos, one of the architects of the temple of Ephesus. But there are no certain indications of geometry as a science before Thales. He laid its foundation in Greece, and infused into his countrymen a taste for the science. He is said to have applied a circle to the measurement of angles, and to have discovered various properties of triangles, by comparing them one with another. In particular, he discovered the important proposition that all angles in a semicircle are right angles, a discovery which greatly delighted him, and for which he expressed his gratitude to the Muses by a sacrifice. Proclus has recorded that he made many discoveries in the science, which, however, have gone to the common stock of geometrical knowledge that had accumulated before Euclid collected it into a system, and the authors of which are unknown. It is probable that the greater part of the disciples of Thales were geometers, but few of their names have descended to us. Ameristus and Anaximander are the only ones now known. Of the former we only know that he was a skilful geometer. The latter wrote a kind of elementary treatise or introduction to geometry, the earliest work of the kind that is known to have existed.

Thales was succeeded in his school by Anaximander, who is said to have invented the sphere, the gnomon, and geographical charts. These required a considerable knowledge of geometrical science. It has been said that he attempted the grand practical geometrical problem of measuring the magnitude of the earth. This probably has originated in his being the inventor of representations of its surface. The honour of being the first to measure the earth seems to belong to another. Anaximander was followed by Anaximenes, born at Miletus 540 years B. C. He is said to have invented sun-dials, and thus must have known both astronomy and geometry; indeed a desire to understand the former would prove a strong stimulus to the study of the latter. He had as his disciple and successor Anaxagoras, who being persecuted for his opinions, employed himself in prison in trying to square the circle. This is the first notice on record of an attempt to resolve what appears now to be an insoluble problem, on which no modern geometer will spend his time. It might, however, have a very different aspect to the ancient mathematicians.

Pythagoras, born about 580 years B. C., was one of the greatest men of antiquity. According to some he was a Tuscan, whilst others say he was a Tyrian; but his name is better known than his origin. At the age of eighteen he became the disciple of Thales, and imbibed deeply his opinion of the importance of temperance and economy of time as necessary to success in the study of philosophy. In the infancy of science knowledge was only to be acquired by travel, the men of different countries standing in the place of our modern books as the depositories of learning. Pythagoras visited Phœnicia, Chaldea, and India. In the annals of this last country the remembrance of the philosophical traveller is still preserved. He afterwards went into Egypt, where he is said to have remained twenty-two years, holding intercourse with the priests. The long duration of his abode is not probable, as the knowledge he seems to have acquired did not correspond to so protracted a residence. Whilst in Egypt, he is said to have consulted the columns of Sothis, on which that celebrated person had inscribed the principles of geometry. He returned to Samos, his adopted country, and there opened his school; but not finding auditors, he removed to Italy, and took up his abode in Cortona, a town in the territory of Tarentum, where he found many disciples, and acquired a great reputation. He is said to have discovered the important theorem in geometry, that in a right-angled triangle the squares on the sides containing the right angle are together equal to the square on the side opposite to it; and on this account he is said to have sacrificed an hundred oxen in gratitude to the Muses. The sacrifice is probably a fable. The shedding of blood was contrary to his moral principles, and so many oxen were not likely to be at the disposal of a philosopher. In his school, geometry made great progress, and was augmented by several new theories, such as that of the incommensurability of certain lines, in particular that of the side of a square to its diagonal. The theory of the regular solids had its origin also in the Pythagorean school, a doctrine which requires an extensive knowledge of geometry. This subject, now neglected amidst the riches of modern mathematics, because of its small utility, was in the beginning of great importance, on account of other discoveries which must have been incidentally made in its prosecution. Diogenes Laertius has attributed to Pythagoras the discovery that of all figures having the same boundary, the circle among plane figures, and the sphere among solids, are the most capacious. If this was so (a thing doubtful), he is the first on record who considered isoperimetrical problems.

The Pythagorean school sent forth many philosophers and mathematicians: amongst the latter, Philolaus and Archytas held a distinguished rank. Of Philolaus we know but little. He held to its full extent the Pythagorean doctrine of the motion of the earth round the sun as a centre, and was the first to unveil it. He composed a work on Mechanics, and thus has a claim to be associated with Eudoxus and Archytas as inventors of that part of mathematics. He had a tragical end, having been massacred by the people of the small republic of which he had been a legislator. We know more of Archytas. He was the author of a solution of the problem of two mean proportionals. He was also one of the first who made use of the geometrical analysis, which, according to Proclus, he had learned from Plato, and by its assistance he made many discoveries in geometry. We pass over his mechanical inventions, one of which, the artificial pigeon, which winged its way through the air, certainly savours of the marvellous. Archytas is said to have been blamed by Plato for applying geometry to mechanics; but if this was so, it might be for the manner of the application. His solution of the problem of finding two mean proportionals gives support to this conjecture; for although ingenious, it has the defect of requiring a motion which cannot be executed.

Democritus of Abdera cultivated geometry extensively. It has been conjectured that he was one of the first who treated of the contact of circles and spheres, and of irrational lines and solids.

Hippocrates, who lived about the year 380 B. C. was originally a merchant; but having no turn for commerce, he did not prosper. To renovate his affairs, he went to Athens, and there for the first time became acquainted with geometry, which seemed to suit his particular turn of mind. In the prosecution of this study he discovered that the curvilineal space, called from its form a *lune*, comprehended by half the circumference of one circle and the fourth of the circumference of another (their concavities being turned the same way), was equal to a rectilineal space, viz. the area of a right-angled triangle, whose hypothenuse was the diameter of the circle, and its sides each equal to the radius of the quadrantal arc. This could not be considered as a true quadrature of a curvilineal space; it was merely a geometrical juggle, by which a common space being taken from two equal curvilineal figures, one of the remainders was by a sort of chance a rectilineal figure. The first true quadrature of a curvilineal space is due to Archimedes. Hippocrates attempted the quadrature of the circle; but, if his mode of reasoning has been truly handed down to us, he committed a great oversight. This is the first recorded paralogism in geometry. He was more successful in treating of the duplication of the cube, which he showed to depend on the finding of two mean proportionals between two given lines. He was also the first who composed elements of geometry, but these have been lost. He appears to have retained the mercantile spirit, insomuch that he accepted money for teaching geometry. On this account he was expelled the Pythagorean school; a measure somewhat hard, considering his reduced circumstances.

Two geometers, Bryson and Antiphon, appear to have lived about the time of Hippocrates, and a little before Aristotle. They are only known by some animadversions of the latter on their attempts to square the circle. Before this time geometers knew that the area of a circle was equal to a triangle whose base is equal to its circumference, and altitude equal to its radius. This truth could not escape the observation of the early geometers. Bryson erroneously believed that, by a geometrical construction, he could find the circumference, in which case the quadrature would have been easy. Antiphon, it appears, proceeded by increasing continually the number of sides of an inscribed regular polygon, and considered the circle to be equal to the ultimate result; a process perfectly correct, and the same in effect as that by which Archimedes found the area of the parabola.

From this brief view of the progress of geometry during the first two centuries after its introduction into Greece, we pass to the school of Plato, in which geometry completely changed its character, and advanced with increased vigour and more rapid strides. Hitherto its subjects had been of the most elementary nature; now, however, the views of geometers became more enlarged, and a new era in the science commenced. Although the disciple and successor of Socrates, who had no taste either for mathematical or physical science, Plato held them in the highest estimation; and, imitating the earlier sages of Greece, he undertook voyages and journeys to improve his mathematical knowledge. He visited Egypt to converse with the priests, and Italy to consult with the celebrated Pythagoreans Philolaus, Timæus of Locris, and Archytas. With the last of these he contracted a particular friendship. He went also to Cyrene to hear the discourses of the mathematician Theodorus; and on his return to Greece, when he had founded his school, he made the mathematics, particularly geometry, the basis of his instructions; and his disciples, encouraged by his example and his exhortations, applied with ardour to the study of that science. He never allowed a day to pass without making his disciples acquainted with some new truth. He placed over his school this inscription, *Let no one ignorant of geometry enter here.* He held that the Divinity continually geometrizes; meaning thereby, no doubt, that the laws by which the universe are governed are in accordance with the doctrines of mathematics. It does not appear that Plato composed any work expressly on the mathematics; but his invention of the geometrical analysis may be considered as one of the greatest improvements the science has received. The theory of Conic Sections originated in the Platonic school; and a third discovery was that of Geometrical Loci, a theory not only beautiful and interesting on account of the abstract truths which it unfolds, but also by reason of its great importance in the resolution of geometrical problems. The celebrated problem concerning the duplication of the cube was agitated about his time; but its origin was earlier; for Hippocrates, as has been already stated, had reduced it to the finding of two continued mean proportionals. Plato himself gave a solution of the problem; and it was also resolved by Archytas, Eudoxus, Eratosthenes, and Menæchmus. The solutions of eleven of the ancient geometers have been preserved in the Commentary of Eutocius on Archimedes' Treatise concerning the Sphere and Cylinder. It is probable that the trisection of an angle, a problem of the same degree of difficulty as the duplication of the cube, excited the efforts of the Platonic school. We have indeed no positive testimony in favour of this conjecture; but the progress of the human mind does not allow us to doubt that the problem was of great antiquity. After the solution of the very simple problem, the bisection of an angle, it was natural to think of dividing it into three equal angles; and those who first thought of the latter problem would no doubt be astonished to find, that two problems so like in appearance should yet differ so much in the difficulty of their solution. The trisection of an angle, and the duplication of a cube, are in fact problems of such a nature that they cannot be resolved by straight lines and circles alone, the only lines admitted by the ancients into their elements of geometry. The reason of this impossibility would not be apparent to the ancient geometers, although it is made evident by the modern doctrines of algebra.

The names of the individuals to whom we owe the particular discoveries which have been specified have not come down to us; they must therefore be regarded as belonging to the Platonic school generally. Proclus has recorded the names of a number of the geometers of that school. Some of advanced years attended it as friends of its celebrated head, or from respect to his doctrines; others, chiefly young persons, as disciples. Of the first class were Laodamus, Archytas, and Theætetus: Laodamus was one of the earliest to whom Plato communicated his method of analysis before he made it public, and he is said to have profited much by the possession of this instrument of discovery. Archytas was a Pythagorean, having extensive knowledge in geometry and mechanics. He frequently visited Plato at Athens; but in one of his voyages he perished by shipwreck. Theætetus was a rich citizen of Athens, who had studied along with Plato under Socrates. He appears to have cultivated the theory of the regular solids, called now the Platonic bodies.

The progress of geometry now required that its elements should be new modelled. This was done by Leon, a scholar of Neoclis, or Neoclides, a philosopher who had studied under Plato. To Leon has been ascribed that part of the solution of a problem called its *determination,* which treats of the cases in which the problem is possible, and of those in which it cannot be resolved. Eudoxus of Cnidus was one of the friends and contemporaries of Plato; he generalized many theorems, and thereby greatly advanced geometry. It is believed that he cultivated the conic sections; and even the invention of these has been ascribed to him. He resolved the problem of the duplication of the cube; and it is to be regretted that Eutocius, who speaks with contempt of his solution, has not recorded it with others in his Commentary on Archimedes. Diogenes Laertius has attributed to him the invention of curve lines in general; from which we may infer, that other curves besides the conic sections were known in the school of Plato. Archimedes, in his Treatise on the Sphere and Cylinder, says that Eudoxus found the measure of the pyramid and cone, and that he was especially occupied with the contemplation of solids. Some have given him the credit of being the writer of the fifth book of Euclid, which treats of proportion. Amongst the numerous mathematicians of the Platonic school, there was one, Cratistus, who is particularly mentioned by Proclus. He was a remarkable person; for his knowledge of his science was in a manner innate. There was no problem of that time, however difficult, which he could not resolve by his natural geometry. He was the Pascal of antiquity. There were two brothers, Menæchmus and Dinostratus, who also greatly distinguished themselves. The former, a particular disciple of Plato, extended the theory of the conic sections. Eratosthenes seems to attribute to him the merit of having invented them; at any rate, he was the first who solved the problem of doubling a cube by means of these curves. Dinostratus followed in the path of his brother, and advanced geometry by his discoveries. He is particularly known as the reputed inventor of a curve called the *quadratrix*, by which he seems to have intended to divide an angle or an arc of a circle in any given ratio. The curve takes its name from a property by which, could it be constructed geometrically, the quadrature of the circle would be obtained. According to Pappus, Dinostratus discovered this property of the curve; and probably this is the reason why it has been called the quadratrix of Dinostratus, just as we say the spiral of Archimedes. Indeed there is some ground for believing that the curve was invented by Hippias, a philosopher and skilful geometer, contemporary with Socrates.

It was chiefly in geometry that the followers of Plato excelled. In this they imitated their leader, who directed his attention to abstract speculations, rather than to the study of nature. The conic sections, one of their most refined and profound geometrical theories, remained merely an intellectual speculation from its first invention till the days of Kepler and Newton, when it acquired a high importance on account of the discovery that the orbits of the planets are conic sections.

The school of Plato, after the death of its founder, was divided into two others, which, although opposed to each other on various points, yet agreed in holding the mathematics in esteem, and in regarding them as an indispensable preparation for the study of philosophy. It is recorded, that a person ignorant of geometry and arithmetic having presented himself for admission into the school of Xenocrates, the successor of Plato after Speusippus, he was repelled by its chief, with an intimation that he was not properly prepared for the study of philosophy: *Ansas philosophorum non habes*, said the philosopher.

The mathematics, thus encouraged and protected, continued to be cultivated and improved. The celebrated geometer Euclid was of this school; and it may be conjectured, from the age in which he lived, that he had acquired his knowledge under the tuition of the first successors of Plato. So also, we may presume, was Aristæus, another celebrated geometer of antiquity, though little known in our time, because his works have perished. We learn, however, from Pappus, that he was one of the ancients who contributed the most to the progress of the sublime geometry. He was the author of two excellent works; one a treatise on *The Conic Sections*, in five books, which contained a great part of what Apollonius has given in the first four books of his work; the other, also in five books, treated of *Solid Loci*. Pappus, in prescribing a course of study to his son, places this last work next in order after the Conics of Apollonius. Hence we may infer that the propositions which it contained were of a higher order of difficulty, and required a previous knowledge of the conic sections. Euclid entertained great esteem for Aristæus. We may hence conclude that he was either his disciple or his intimate friend.

The pure mathematics were less cultivated in the school of Aristotle than they had been in that of Plato; they were not, however, neglected; for, unlike the modern peripatetics, who discouraged the study of geometry. Aristotle was deeply versed in the science, as may be inferred from his writings, which abound in examples drawn from geometry.

Although the mathematics received but little addition in the Aristotelian school, still they had some cultivators. Of these, Theophrastus was the principal. He wrote some treatises relating to them, particularly a complete history of these sciences down to his time, a work which has unfortunately been lost. It consisted of four books on the history of geometry, six on that of astronomy, and one on that of arithmetic. We have great reason to regret the want of the sure light which this work, had it come down to our times, would have thrown on the origin and progress of these sciences, instead of which, we have only a few glimmerings, that serve to make the darkness sensible, but not to dissipate the obscurity. Another disciple of Aristotle, Eudemus, composed a history of the mathematics. This consisted of six books on the history of geometry, and as many on that of astronomy. We owe to these all we now know concerning the origin of those sciences; for it is from this source that Proclus, Theon, and Diogenes Laertius have drawn the few notices which they have transmitted to us.

We come next to a new epoch in the history of the ancient mathematics. This was the institution of the school of Alexandria. However memorable this event may have been in the history of general literature, it is more especially remarkable in that of the mathematics; for in this celebrated school all the mathematical sciences were cultivated with a degree of care not inferior to that which had been bestowed on pure geometry in the school of Plato, and with corresponding success.

The period which immediately followed the death of Alexander proved one of trouble and confusion. The vast empire founded by that conqueror was dismembered by his principal captains; and Egypt was the portion which fell to one of them, Ptolemy Lagus. As soon as he had established tranquillity in his dominions, Lagus turned his attention to the sciences; and by his encouragement of their cultivators, he drew to him many of the learned of Greece; and his capital soon rivalled Athens as the resort of men of knowledge and talent. These constituted the Alexandrian school. The perfection of this celebrated establishment is mainly due to his son and successor Ptolemy Philadelphus, who bestowed on the learned men he had induced to settle in his capital, protection and liberal encouragement. Amongst those who resorted to this institution, none has been more celebrated than the Greek geometer Euclid. His country is unknown; and of the events of his life no notice has reached us. It appears that he had resided in Greece, and studied geometry under the disciples of Plato. Thence he went to Alexandria, induced probably by the liberality of the first Ptolemy. Pappus has described him as gentle and modest, and entertaining a particular regard for those who could contribute to the progress of the mathematics. His character formed a contrast to that of Apollonius, another geometer, who was vain, and delighted in depreciating his contemporaries. We may suppose that Euclid was not much of a courtier, from his reply to Ptolemy, who inquired of him whether there was not an easier way to a knowledge of geometry than the study of his Elements. "There is no royal road to geometry," was his answer. We have elsewhere (see EUCLID) given a full account of this distinguished geometer and his writings.

The great excellence of the Elements of Euclid must increase our regret for the loss of a treatise which he composed on *Porisms*. Of this work, all that has come down to modern times is an abstract, inserted by Pappus Alexandrinus in his Mathematical Collections. This, however, has suffered so much from time, that all we can immediately learn from it is, that the ancients put a high value on porisms, and regarded them as an important part of their analysis. The efforts of modern geometers had been exerted in endeavouring to discover the nature of porisms, but without much success. At length Dr Robert Simson, with a zeal and perseverance not to be surpassed, succeeded in divining their nature, and even in restoring a great number of Euclid's propositions. These form a part of the posthumous works of this distinguished geometer.

Leaving the Alexandrian school, our attention is drawn to Sicily, which gave birth to Archimedes, a geometer whose genius has been the admiration of all who have come after him. His life was written by Heraclides; but this precious piece of biography, so well calculated to interest our curiosity, has unfortunately perished. Archimedes was born 287 years before our era. He was the relation and friend of Hiero, king of Syracuse. His skill as a mechanician is universally known; but it is only as a geometer that we shall speak of him here. Endowed with a mind of the highest order, he exerted it in the extension of mathematical science. The measure of curvilineal magnitude was a subject new in his time, concerning which but little was known. Archimedes attached himself to this branch by predilection, and opened new views, which have engaged the attention and exercised the genius of such men in modern times as Kepler, Cavalieri, and Dr Wallis. The last of these has called him a man of prodigious sagacity, who first laid the foundations of almost all that had given celebrity to the seventeenth century of our era.

The writings of Archimedes were numerous. We have two books by him on the sphere and cylinder, which terminate in the fine geometrical discoveries, that the solidity and surface of the sphere are respectively two thirds of the solidity and surface of the circumscribing cylinder, with which he was so much delighted, that he desired that these figures should be inscribed on his tomb. His book on the measure of the circle is a kind of supplement to his treatise on the sphere, which supposed a knowledge of that measure. The determination of the exact ratio of the diameter to the circumference was, as at present, a problem not to be resolved; but he found limits to that ratio, and an approximation to it sufficiently accurate for the ordinary wants of the arts, which was all that he attempted. He might, however, have carried his approximation farther, as was afterwards done by Apollonius, and by Philo, another geometer less known.

Archimedes having succeeded in measuring the sphere and cylinder, bodies long the study of geometers, he opened a new field of inquiry in his Treatise on Conoids and Spheroids. All his determinations are now familiar to geometers; his processes of reasoning are highly ingenious, but withal somewhat intricate. Indeed we question whether many modern mathematicians have had patience to go through his investigations, considering that the same conclusions can now be reached by much shorter methods.

The properties of the spiral, invented by his friend Conon, and the quadrature of the parabola, are among the additions made to the ancient geometry by Archimedes. This last was a grand step in the progress of geometry; because it was the first curvilineal space legitimately squared, and the only one, until the application of the modern methods of analysis. In latter times the notion of infinity has been introduced into geometry, and has contributed greatly to its extension. The ancients, however, carefully avoided this term, which might have injured the stability of the science. Their theory of exhaustions supplied its place, and was a safe, although a laborious and indirect way of establishing truth. The writings of Archimedes give the finest examples of its application. We pass over the mechanical and optical inventions of this great man, and only observe that they indicate a state of considerable perfection in the geometrical science of that period.

The writings of Archimedes are the most important of the few classic remains of ancient geometry which we now possess. The subjects of which they treat, being less elementary, are now less studied than those in the Elements of Euclid. Every geometer, however, should have read them at least once in his life. The earliest edition of his writings was published at Basle in 1644. It was in Greek, with a Latin translation by Venatorius, the two versions being printed as separate volumes, and accompanied by the Commentary of Eutocius. There have been many editions of his works. Of these we shall only notice two; that of Torelli, in Greek and Latin, published at Oxford in 1792, and a French translation of his writings by Peyrard, the learned editor and translator of Euclid's works.

Returning to the school of Alexandria, we have to mention Eratosthenes, a geometer as well as an astronomer. Indeed he was one of those uncommon men, whose genius embraces all subjects; for he was also an orator, a poet, an antiquary, and a philosopher. His extensive knowledge induced the third Ptolemy to make him his librarian. He chiefly cultivated geometry and astronomy, and has been classed with the three great geometers of antiquity, Aristæus, Euclid, and Apollonius, who had improved geometrical analysis. Pappus mentions a work by Eratosthenes on this subject, in two books. He has told us its title, but has not described its exact object, which can therefore only be conjectured. He gave a solution of the problem of the duplication of the cube, which Eutocius has preserved in his Commentaries on Archimedes; and he applied his geometrical and astronomical science to the solution of the grand problem, the measurement of the magnitude of the earth, which, however, had been attempted before his time.

Apollonius of Perga appeared as a geometer in the Alexandrian school, about the time when Archimedes had finished his career. It might be a question which of these two great men was endowed with the higher genius; for such was the estimation in which Apollonius was held at the period in which he lived, that he obtained the appellation of the *great geometer*. He was the most profound and fertile writer that has ever treated of geometry. His works which have survived the ravages of time, or have been restored by modern geometers, with the addition of the Data and Porisms of Euclid, this last also a restoration, constitute nearly all which we now know of that beautiful subject, the ancient geometrical analysis. Whoever would understand it, and acquire skill and facility in its application, would do well to study with care the various works of Apollonius which have been restored, if not exactly according to the letter, at least in the true spirit of the originals. A full account of the writings of this distinguished geometer has been given as an article of biography (see APOLLONIUS); it is therefore unnecessary to enumerate them here.

The ancient mathematicians addressed their writings to others, their particular friends. It is in this way that the names of some of their contemporaries have descended to us, although their writings have been lost. Apollonius dedicated the first three books of his Conics to Eudemus, a geometer, and in such terms as show that he addressed himself to one well acquainted with the subject. He says that he had been encouraged to study the subject by Naucrates; and he requests Eudemus to communicate what he had written to Philonides, also a geometer. Eudemus having died, he addressed the fourth book to Attalus, and speaks of Thrasydeus, with whom Conon of Samos, a little anterior to his time, had held a correspondence on the conics; also of Nicoteles the Cyrenean, who it seems had a controversy with Conon. The regret which Archimedes expresses for the loss of Conon gives us reason to believe that he was a profound geometer. We know also that he was an astronomer. Archimedes dedicated several of his works to Dositheus, another geometer, whose name has thus become known to us.

It was about this period that the geometer Nicomedes lived. He was the inventor of the *Conchoid*, a curve which served to resolve two remarkable problems, the duplication of the cube, and the trisection of an angle.

The period which comprehended the ages of Euclid, Archimedes, and Apollonius, was that in which the science of geometry shone forth with the greatest splendour. It had been in a state of gradual improvement from the time of Thales. Now, however, it seems to have arrived at a degree of perfection beyond which its cultivators did not carry it. We may suppose that the science of astronomy took its place, and presented a new and more inviting field of discovery. Hipparchus, the father of astronomy, was also a geometer; for we find him applying its principles, combined with arithmetic, to his science.

There were geometers who were also mechanicians. These, as well as the astronomers, probably cultivated geometry alone as connected with their own science. Gemimus of Rhodes lived between the time of Hipparchus and the beginning of our era. He was the author of a work on geometry, and another on astronomy. The former, which is lost, was probably a historical commentary, a sort of development of geometrical discoveries. Proclus seems to have drawn from it all that he has said on the history and metaphysics of geometry. Its loss is matter of regret. Ctesibius, and Hero his disciple, were celebrated as mechanicians. The former lived in the middle of the second century before Christ. Philo of Byzantium was also a celebrated mechanician. Possidonius was at once geometer, astronomer, mechanician, and geographer. He deserved well of geometry, for having repelled the attack of Zeno the Epicurean, who had attempted to invalidate its principles and certainty. Dionysiodorus was a skilful geometer, as appears by his solution of a difficult problem of Archimedes. Theodosius was the author of a work on the geometry of the sphere, which has descended to our times. It appears to have been studied as a classic in the English universities. Dr Barrow gave an edition of it, along with the writings of Archimedes, and the four books of the Conics of Apollonius, in 1615. The best edition is that of Hunt, printed at Oxford 1707.

The study of the mathematical sciences, which languished in the first century of the Christian era, revived a little in the beginning of the second. Menelaus, an astronomer, wrote on trigonometry and spherical geometry. This work has reached our times by a translation from the Arabic. Dr Halley, holding in high esteem every vestige of the ancient geometry, had prepared a new edition of this geometer, corrected from a Hebrew manuscript. It did not appear, however, until 1758, by the care of Costard, the author of a history of astronomy. Menelaus, as we learn from Pappus, cultivated the theory of curve lines; a subject which may be regarded as belonging to the higher geometry among the ancients.

Ptolemy, if not an inventive geometer, must at least have been perfectly acquainted with its theories, for he had the merit of applying them to astronomy. His Almagest has handed down from antiquity a beautiful geometrical theorem, the foundation of the Greek trigonometry. It is this; the rectangle contained in the diagonals of a quadrilateral inscribed in a circle, is equal to both the rectangles contained by the opposite sides.

Several mathematicians of no great note lived in the third and fourth centuries of the Christian era. Such were Serenus, who wrote two books on cones and cylinders; Hypsicles of Alexandria, the supposed author of two books on regular solids, sometimes ascribed to Euclid; and Perseus Citticus, who wrote on certain lines called *Spiriques*, formed from a solid generated by an arc of a circle revolving about a fixed axis. Philo of Thyaneus, and Demetrius of Alexandria, both wrote on curve lines.

We are now come to a period in which the sciences had begun to decline; when, instead of original treatises, writers were content to compose commentaries and annotations on the works of their more illustrious predecessors. It was in this way that Pappus and Theon of Alexandria, who lived towards the end of the fourth century, rendered service to the mathematical sciences. The first, however, must not be classed with the ordinary scholiasts; for in his Mathematical Collections he has shown that he was an expert geometer. His object in composing this work was to collect into one body many scattered discoveries, and to illustrate and supply deficiencies in the writings of the celebrated mathematicians who had preceded him. He has done this in regard to Apollonius, Archimedes, Euclid, and Theodosius, by a number of lemmas and important propositions which they had assumed as known. His writings have made us acquainted with the various attempts made by the ancients to double the cube, and to divide an angle into three or more equal parts. We are indebted to him for almost all we know of these and other important matters in the ancient geometry; and it is through his writings that the names of many geometers have come down to our days, which, but for him, would have been lost in the obscurity of time. The preface to his seventh book is of inestimable value, inasmuch as it has preserved from oblivion many of the analytic works of the ancients. His brief analysis of these works, for that is all we have, has given continuity to the history of geometry; and his indications have served as vestiges of the steps by which the ancients proceeded in their discoveries. Guided by these brief notices, the ingenuity of the moderns has succeeded in restoring the writings of Apollonius and Euclid, which had disappeared for ages. It is not improbable, that in this renovated form, the works of these geometers surpass in excellence the originals. The restorers have had the advantage of an improved state of the science, and the works of later geometers, to assist them in their researches.

It is probable that at this time there is not an entire copy of the eight books of Pappus in existence; certainly there is none in Britain. In a catalogue of the manuscripts of England and Ireland, published at Oxford in 1698, there is mention made of two copies in the Savilian library. These have been more than two centuries in Oxford. One, marked No. 3, is in folio, and is well written on paper; it contains the Greek text of the third, fourth, fifth, sixth, seventh, and eighth books, and in addition some works of Theodosius and Autolycus. There is no memorial to indicate when it was written, or by whom. The other copy, with a mark No. 9, is not so well written; it has been copied by various hands, on separate sheets of paper. This copy, besides the books preserved in the former, contains also a part of the second book. Dr Wallis has spoken of three manuscripts of Pappus at Oxford, one in the Bodleian and two in the Savilian library. No traces of a third copy can now be found in the Bodleian library. The late Dr Trail, in his life of Dr Robert Simson, has described a manuscript now in the Advocates' Library, Edinburgh. It contains five books of Pappus, viz. the third, fourth, fifth, sixth, and eighth; but unfortunately the seventh, the most valuable portion of the work, is wanting. This was purchased at Paris by Dr James Moore in 1748.

The British Museum possesses a manuscript copy of Pappus, which had been the property of the Saliante family at Verona. None of the manuscripts of which we have any details are of a very early date. There are some points of resemblance in all that have been examined, which seem to indicate a common origin. It is well known that early manuscripts are few in number; sometimes only one is known. This may have been the case in regard to the text of Pappus, and will account for the agreement of all the manuscripts in particular places. We owe the edition which we possess of this ancient work to the labour of Commandine, who translated and enriched it with notes, but died when he was about to give it to the world. It afterwards appeared in 1588, under the patronage and by the pecuniary aid of Francisco Maria, duke of Urban. That part of the second book which has been preserved was published in the third volume of the works of Dr Wallis: it treats of the ancient arithmetic.

We had formerly occasion to mention Hypatia, the daughter of Theon, as a commentator on Diophantus, in our account of the progress of Algebra. She has a claim to our notice also in the history of geometry, by her having composed a commentary on the writings of Apollonius.

The philosopher Proclus, the chief of the Platonic school at Athens, made it in some measure the seat of the mathematical sciences about the middle of the fifth century. In imitation of the chief of his sect, he held the sciences in great estimation. He was not, however, distinguished for original discoveries; but his commentary on the first book of Euclid, setting aside the fault of its prolixity, is valuable, because of the information it contains on the history and metaphysics of geometry at a remote period.

We pass over several geometers of this period, of whom hardly any thing but their names is known. We mention, however, Diocles as the inventor of a curve called the cissoid, contrived for the solution of the celebrated problem, to find two mean proportionals.

Geometrical science had by this time been long on the decline. The Alexandrian school, however, still existed; and a repetition of such a period as that in which Apollonius and Euclid flourished might have been hoped for, had it not been for the troubles which agitated the East. The taking of Alexandria by the Saracens in the year 640 gave a deathblow to the sciences, not only in that celebrated city, but throughout the Greek empire. The library was delivered over to destruction by the command of the ignorant fanatic Omar; and this, the finest monument of human genius, the accumulated store of knowledge that had been collecting for ages, was employed during six months in warming the four thousand baths of Alexandria. Such was the end of the Alexandrian school, which had for nearly ten centuries contributed to the advancement of the human mind in knowledge.

About the eighth century we find Hero, called *the younger*, an engineer and mathematician. He wrote a treatise on *Geodæsia* (so practical geometry was called), which had no great merit; it is, however, remarkable for containing, without demonstration, a rule for finding the area of a triangle when its three sides are known. There is no notice of this important theorem in the writings of the ancients which have come down to us. It was, however, probably found by some geometer earlier than Hero. It appears to have been afterwards lost, and rediscovered by Tartalea.

We have an unfavourable opinion of the modern Arabians, but there was a period when they had a very different character. When the sciences were neglected by the Greeks, and existed only in manuscripts buried in the dust of libraries, the Arabians brought them forth from obscurity, and gave them an honourable asylum. They were the depositaries of knowledge during the ages of barbarism and ignorance which overspread Europe; and we owe to our intercourse with them the first glimpses of light which penetrated the obscurity of the eleventh, twelfth, and thirteenth centuries. The Arabians diligently cultivated the science of astronomy ; and as a corresponding knowledge of other branches of science was necessary to success, they became geometers, opticians, and even algebraists. The greater part of the Greek geometers, particularly those necessary to the study of astronomy, as Euclid, Theodosius, Hypsicles, Menelaus, were translated into the Arabic language in the time of Almamon, or soon after him. They even began to cultivate the sublime geometry of the ancients, for the four first books of the Conics of Apollonius were translated by order of that prince. They added to their literature the writings of Archimedes, and at least three of the last books of the Conics of Apollonius ; and all these works are to be found in libraries rich in oriental manuscripts. It is from the last-mentioned work, corrected and augmented by the notes of Nassireddin, a Persian geometer, that Dr Halley has enriched our geometry with the fifth, sixth, and seventh books of the ancient Greek author ; the remaining books, viz. the eighth, appear however to have been entirely lost. The Arabian writers quote the writings of several Greek geometers of which we know nothing, such as a treatise on parallel lines, another on triangles, and a third on the division of the circle. We must allow to the Arabians the merit of having given to our trigonometry its present form. They also simplified the practice of its operations, by employing the sines of the arcs instead of the chords of the double arcs employed by the Greeks. This was even one of their earliest inventions, for we find it in the writings of their astronomer Albatenius.

The Arabian historians have recorded the names of several of their cultivators of geometry ; but these may be passed over, ignorant as we are of their contributions to the science. The optician Alhazen however deserves notice, because of the knowledge of geometry shown in his writings, and also on account of a geometrical problem applicable to optics which bears his name. The solution he gives was probably derived from the Greek geometers. It must be confessed the Arabians do not appear to have been an inventive people ; almost always commentators or compilers, they seldom rose higher than the labours which such functions impose.

The Persians have also had their geometers. The most celebrated was Nassir-Eddin Al-Tussi. The science is indebted to him for some good works, particularly a learned commentary on Euclid, which was written in Arabic, and printed in 1590 in Italy. Another geometrical work is a revision of the Conics of Apollonius, with a commentary. Dr Halley found this useful in remodelling the fifth, sixth, and seventh books of that precious treatise. The Persian geometers have long known the principal Greek writers ; and they even profess to have some of their writings which we have not known. It appears that their geometers had a peculiar taste in treating the doctrines of abstract science, for they have given every proposition of the elements a name expressive of one of its uses, or of some fanciful analogy it may have to things foreign to geometry. The forty-seventh of the first book of Euclid, for example, they call the *figure of the bride*, and the forty-eighth the *bride's sister ;* and, with some reason, they call the mathematics the *difficult science*. Mathematical knowledge among the Turks has been nearly in the same state as among the Persians. The libraries of Constantinople contain Arabic and some Turkish translations of the Greek writers. Geometry is taught in their schools, but it does not appear that they go beyond the Elements of Euclid. There are hardly any traces of geometry amongst the Hebrews. We know that when Solomon's temple was built, Hiram king of Tyre furnished architects and navigators. From this we may infer that the Jews had no geometry at that period. It was not before their second dispersion that they took an interest in the sciences. However, when mixed with other nations, some of their learned men cultivated geometry, but never proceeded beyond the elements. About the time of Almamon, in imitation of the Arabians, they translated the writings of some of the Greek mathematicians into their language, in particular those of Euclid and Archimedes. They however made no addition themselves to geometrical science.

The researches of Europeans concerning the mathematical and astronomical science of India have discovered among the Hindus some works on geometry of great antiquity. We have already given some account of these interesting writings in our sketch of the history of Algebra ; and we have there described the *Lilavati*, a work on arithmetic and geometry by Bhascara Acharya, a Hindu mathematician, who lived about the year 1150 of the Christian era. In another work, reputed more ancient, viz. the Surya Siddhanta, we find a rational system of trigonometry combined with fable and absurdity. There has been great difference of opinion as to the time when this last treatise, the most ancient on the Indian astronomy, was written. The French astronomer Bailly believed it to have been composed more than 3000 years before the Christian era ; but more sober inquirers have judged it to be about 750 years old. The trigonometry it contains is probably much older. The Hindu books on geometry are remarkable for not containing demonstrations. The writers knew the celebrated proposition concerning the squares on the sides of a right-angled triangle, the discovery of which is ascribed to Pythagoras ; and they also knew the rule for finding the area of a triangle from its sides, which was not known to the early Greeks. It appears from the Institutes of Akbar, that the Indians supposed the diameter of a circle to be to its circumference as 1250 to 3927 ; which is the proportion of 1 to 3·1416, and is more accurate than the determination of Archimedes, or indeed than any known before the sixteenth century.

The Chinese have cultivated astronomy from a remote antiquity, yet it does not appear that they have made any progress in geometry. They knew the proposition of Pythagoras, it would seem, earlier than it was known to the Greeks, yet it remained sterile in their hands. They had no spherical trigonometry before the thirteenth century, and then it was not of native growth ; it was probably derived from the Arabians or Persians.

The Romans, unlike the Greeks, gave little attention to the sciences. The mathematics in particular were disregarded at Rome ; and geometry, scarcely known there, did not extend beyond the art of measuring land and of fixing boundaries. The mathematics were, however, not unknown to Cicero. The respect with which he speaks of them, and the veneration he manifested for the memory of Archimedes in searching for his tomb, on which he knew were inscribed a sphere and cylinder, indicate that he had given some attention to the subject of geometry.

The Roman geographer Strabo must be numbered amongst the geometers of his day : and Cicero mentions another, Didymus, who was blind ; but he was a Greek by birth. Vitruvius has given much information, in his architecture, on matters connected with geometry.

We pass over those ages in which the sciences had nearly disappeared in Europe, and hail with satisfaction their revival in the eighth century. Mathematical science was at first dimly recognised, like the dawn of a new day after a gloomy night, in the writings of Boethius, Bede, his disciple Alcuin, and Gerbert, who travelled into Arabia, the only country where a knowledge of the mathematical sciences could be acquired. In this he was imitated by the English monk Adelard, or Athelard, in the twelfth century, who went into Spain and Egypt ; also by other

Englishmen, such as Daniel Morlay, Robert of Reading, William Shell or William de Conchis, Clement Langton, &c. Adelard on his return translated Euclid, and he appears to have been the first who made this writer known in the West. His work was never printed. Plato of Tivoli translated the Spherics of Theodosius into Latin about 1120; but this translation was not printed before 1518. It is worthy of remark, that almost all the restorers of the sciences were ecclesiastics, who in the seclusion of the cloisters studied the works of the ancients which had been preserved in the monasteries. This at least is one benefit the world has received from the leisure of the monks of that period, which all of them did not spend in idleness.

The sciences found many cultivators, and much encouragement from sovereigns, in the thirteenth century; Jordanus Nemorarius, who lived about 1230, was well versed in geometry and arithmetic. John of Halifax, known also by the name of Sacro-Bosco, his contemporary, was a mathematician. Campanus of Navarre, the celebrated translator and commentator of Euclid's Elements, was of this age. Almost all the early editions of this work were made from his version and his manuscript commentary. We have a treatise by him on the Quadrature of the Circle. But he deviates from geometrical accuracy, by mistaking the approximate ratio found by Archimedes for the true and exact ratio. The paralogism which he gives for a demonstration may, however, be excused in the geometers of his time. They were few, and their writings must not be too nicely scanned. The name of Roger Bacon is so identified with the progress of science, that we must reckon him among the geometers of his day. In support of this claim we record his treatise on Perspective, a geometrical theory.

Leonardus of Pisa, who in the fifteenth century brought algebra into Italy, was also known as a cultivator of geometry. He composed a treatise on the subject, which Commandine thought worthy of publication, and had prepared it for the press; but his death prevented its appearance.

In the beginning of this century, Cardinal Cusa acquired reputation in geometry, by a pretended quadrature of the circle, and other writings. These, however, were only a tissue of paralogisms. It appears from the introduction to a tract of this writer, that Pope Nicolas V. who occupied the pontifical throne from 1447 to 1455, was a geometer, and had translated the works of Archimedes from Greek into Latin. The true restorers of mathematical science in the fifteenth century were Purbach and Regiomontanus. Purbach banished the use of sexagenary calculation from trigonometry, which he enriched with several new propositions. He supposed the radius divided into 600,000 parts, instead of the divisions used by the ancients; and in place of the chords of the double arcs, expressed in sexagenary parts of the radius, he calculated the sines in 600,000ths of the radius. He was the inventor of the geometrical square, an instrument used in practical geometry; and he appears to have been the first who applied the plumb-line to mark the divisions of an instrument. Regiomontanus, whose true name was John Muller (called also *John of Mont-Royal*), was born in 1436. At the age of fourteen he was captivated with the mathematical sciences, and put himself under the guidance of Purbach. The preceptor and his pupil made a journey into Italy to study Greek, in order that they might draw their knowledge from the pure sources of antiquity. Purbach died there, but his disciple followed out his purpose. He afterwards translated the Spherics of Menelaus and Theodosius into Latin; he corrected from the Greek text the ancient version of Archimedes made by Gerard of Cremona; he translated the Conics of Apollonius, and the Cylindrics of Serenus, besides other works on mixed mathematics; he commented on the books of Archimedes, which Eutocius had not touched. He defended Euclid against the imputations of Campanus, and he confuted the pretended quadrature of Cardinal Cusa. We pass over for the present his improvements in trigonometry.

Lucas Paciolus, or Lucas de Burgo, the author of the earliest printed book on algebra, contributed by the same work to the establishment of geometry. It was first printed in 1494, and was therefore one of the early printed books on the science, but not the earliest, for the first edition of Euclid was in 1482.

The decline of the Greek empire, and the taking of Constantinople, which happened in 1453, scattered the learned men of that country, many of whom took shelter in Italy, and brought with them their language, and the precious remains of ancient learning. The art of printing soon spread abroad these treasures, and in the sixteenth century geometry was very generally cultivated. Amongst the writers on the science in this century we may, in particular, reckon Zamberti, John Baptiste Memmius, Commandine, Guido Ubaldo, Maurolycus, and Tartalea. These and others laboured usefully on the ancients, by translations and commentaries. The Jesuit Clavius deserves particular mention. Besides his labour on Euclid, we owe to him a good work for the time on practical geometry in eight books.

We pass a multitude of names, and come to the French geometer Vieta, who was deeply versed in the ancient as well as in the modern geometry, and the restorer of the tangencies, one of the lost works of Apollonius. Adrian Metius, a Dutch geometer, deserves to be mentioned for his convenient and accurate approximate ratio (113 to 355) of the diameter to the circumference of a circle, given in a work on practical geometry. At this period the geometer Nonius, a professor at Coimbra, laboured with zeal in spreading a knowledge of the science in Portugal.

The seventeenth century opened propitiously for the progress of geometry. Lucas Valerius, an Italian, took up a subject which Archimedes had neglected, namely, the centre of gravity of solids; and Marinus Ghetaldus, another Italian, made an attempt to restore the lost book of Apollonius, entitled *De Inclinationibus;* but he left the labour incomplete. He also composed a work *De Resolutione et Compositione Mathematica*, which proves him to have imbibed the true spirit of the ancient geometry. A Scottish geometer, Alexander Anderson, lived at this time. He had a decided taste for the ancient analysis, of which he gave an essay in his *Supplementum Apollonii Redivivi*, in which he supplied what Ghetaldus had left imperfect. The Netherlands could boast of some geometers who did credit to their time. Ludolph Van Ceulen has been celebrated for his approximation to the ratio of the diameter of a circle to its circumference (ALGEBRA, art. 272), a prodigious effort of labour, but requiring little genius. Willebrord Snellius was a more distinguished geometer. He undertook the restoration of the lost book *De Sectione Determinata* of Apollonius, and accomplished his task creditably. He improved greatly the way in which Ceulen had approximated to the ratio of the diameter to the circumference, and verified the labour of that model of patience in calculation. Albert Girard has acquired great reputation in geometry by his supposed divination of the Porisms of Euclid; for in his edition of Stevinus he positively avers that he had restored the three books, which, however, never appeared; and indeed it may be doubted whether he understood the true nature of porisms. John Neper might be reckoned amongst geometers, but he has still higher claims to the notice of posterity for his invention of logarithms.

The science was sedulously cultivated in England at this period by Robert Record, John Dee, Leonard and Thomas Digges, and Henry Billingsley. Record was the author of the *Pathway of Knowledge*, the earliest book in the English language on geometry. It was first printed in

1551, and is dedicated to Edward VI. Edward Wright, the inventor of what is called *Mercator's Chart*, was an English geometer whose knowledge of the science greatly exceeded what was common in his time.

Germany had many geometers at this period, but none of a high order. John Werner of Nuremberg cultivated the ancient geometry, and excelled in a knowledge of its analysis. Every writer on geometry at this period gave a system of trigonometry nearly the same as we now have it in its most elementary form. To George Joachim Rheticus mathematical science is particularly indebted for a trigonometrical table, more extensive than any that had been given before him. It was printed in 1594, with this title, *Opus Palatinum de Triangulis;* but the author was then dead. The work was published by Valentine Otho.

Pitiscus, another German geometer, extended and reprinted this work in 1613, with the title of *Thesaurus Mathematicus, sive canon sinuum ad radium* 1,000,000,000, &c. This is indeed a treasure, and one of the most remarkable monuments of human patience extant.

Want of space compels us to pass in silence many names not less celebrated than some we have given, but less remarkable, because of their abundance in respect of the age to which they gave splendour. Indeed we may reckon that every astronomer and algebraist was then a geometer.

Kepler opened an unexplored way into the field of geometry, by boldly introducing the notion of infinity into that science. We may suppose that Archimedes must have entertained in effect the same idea in his speculations on the sphere and cylinder, but was prevented from following it to its full extent by the strict laws according to which the early mathematicians had constructed their demonstrations. The views of Kepler were eagerly seized by Roberval in France, and by Cavalieri in Italy. They were the fertile germs which, under the culture of such men, led, in the course of the seventeenth century, to a rich harvest of discoveries.

We have now arrived at a period at which the discoveries of the ancients formed but a small part of the whole body of geometrical science, augmented as it had been by the moderns, and which was continually increasing. The new views which were opened soon produced the methods of indivisibles of Cavalieri and Roberval, the theory of tangents of Fermat, the arithmetic of infinites of Wallis, the geometry of curve lines of Descartes, and, finally, the method of fluxions of Newton, and the differential calculus of Leibnitz. The origin and progress of these have been fully explained in our introductions to ALGEBRA and FLUXIONS, and require not to be here repeated. The ancient geometry, however, still had great value. Huygens and Newton delivered their sublime discoveries in its language, and represented the relations of time, space, velocity, force, the objects of their physical inquiries, by geometrical diagrams. The rigorous mode of ancient demonstrations served likewise as a model on which to form the processes of reasoning by which the new truths in geometry and physics were to be established.

Not to pass altogether in silence the names of geometers whose discoveries have made the seventeenth century ever memorable, we observe, that to Guildin, a Jesuit, we owe the discovery of a property of the centre of gravity applicable to the measurement of solids formed by revolution; and to Descartes, Fermat, Roberval, and Barrow, a method of determining the tangents of curves. Galileo first suggested the *cycloid,* the nature of which was afterwards fully disclosed by the investigations of Roberval, Fermat, Pascal, Huygens, Wren, and Wallis. James Gregory first suggested the logarithmic curve; and John Bernoulli and Leibnitz showed the true nature of the catenary, which Galileo could not discover; afterwards, David Gregory demonstrated its properties by the new geometry.

The ancient geometry came in for a share of that general attention which was bestowed on the modern theories. Newton, as has been already stated, held it in high esteem; and David Gregory and Dr Halley employed their genius and learning in restoring to their pristine excellence the precious remains of Euclid and Apollonius.

Previously to the time of Newton, pure geometry and algebra were the only subjects which mathematicians had for the exercise of their genius; but his sublime discoveries presented a new and an immense field for investigation. The fact that the orbits of the planets are ellipses, naturally connected the doctrines of astronomy with the conic sections; and the two were wrought up into the beautiful physico-mathematical theory of central forces delivered in the *Principia.* When this came to be fully understood, it served as a model of reasoning in all speculations on physics, and the geometrical method of Newton was adopted and imitated by his followers. Thus, we have the *Elements of Physical and Geometrical Astronomy* of David Gregory, and the *Phoronomia* of Herman, and many other like treatises, composed in the geometrical style. It was, however, soon discovered, and first by foreign mathematicians, that the geometrical method, which, when carried a certain length, is perspicuous and easy, is yet unsuitable to the more difficult speculations of mechanical philosophy, by reason of its cumbersomeness. It was therefore abandoned by Leibnitz, the Bernoullis, Euler, and their followers, and the greatly more manageable modern methods of the fluxional or differential calculus adopted in its stead. The mathematicians in Britain, who had imbibed deeply and acquired a relish for the spirit of the geometrical method, however, still adhered wholly or in part to that method. Maclaurin, the expositor of Newton's calculus of fluxions, defended its principles, and delivered many of his own fine speculations in the pure and mixed mathematics, in the prolix style of the ancient geometry. But he also gave a theory of the fluxional calculus in the more concise language of the modern analysis, which served as a practical example of the advantage which the latter has over the former as an instrument of invention. Dr Robert Simson, the editor of Euclid, greatly preferred the geometrical to the modern analysis; and his disciple, Dr Mathew Stewart, the author of *General Theorems, Tracts relating to Physical Astronomy,* and *Propositiones Geometricæ more Veterum Demonstratæ,* fully agreed with him in this sentiment. At a later period another Scottish professor, the late Mr Playfair, with a profound knowledge of both the ancient and modern analysis, and with no prejudice in favour of the former, yet gave an elegant example of its beauty, in his paper on the origin and investigation of porisms.

These distinguished Scottish mathematicians, by their writings, contributed greatly to keep up the taste for geometry in Britain during the last century. It is proper to acknowledge also, that much is due to Dr A. Robertson, the late professor of astronomy at Oxford, to Dr Horsley, bishop of Rochester, and others, for the estimation in which the geometrical analysis is now held in Britain.

The nature and objects of the ancient geometry have been fully understood for a century past, and the only question now is, how it ought to be studied. There have been a great variety of treatises within that time sent into the world. We do not, however, suppose that the science has gained by this diversity of guides. The settled public opinion seems to be in favour of some standard book; and Euclid's *Elements* have been, by almost universal consent, chosen as that standard in this country. There is another work of great excellence in the French language, *Eléments de Géométrie,* by the late Legendre, a mathematician of the highest celebrity. Were we to chuse a book different from Euclid for purposes of instruction, it would be Legendre's Geometry, of which there is an English translation. It may be useful to read more than one book on a subject which we wish to understand thoroughly, and those who hold this opinion can find no better book than that of the French geometer. We have kept him constantly in view in composing this treatise.

In tracing the progress of a science, it is always interesting to know by what steps it has advanced in the career of improvement. These may be well ascertained by consulting the authors who have written on the science, from its infancy downwards. With this view we have given a catalogue of writers on algebra and fluxions, and we now do the same in regard to geometry. The early writers are not so much mentioned for their excellence, as from a wish to give a faithful portraiture of the state and progress of the science at different periods. The works on geometry in the last century are too numerous to be all specified. Many have fallen into obscurity. Almost all are mere transcripts from Euclid; indeed, generally speaking, their excellence is in proportion to the fidelity with which they have copied the ancient.

Ancient Writers on Geometry.

Euclid, Elements of Geometry	flourished B. C. 272
First edition in Latin, that of Ratdolt	1482
First edition of Greek text, by Hervage,	1533
Edit. in Greek, Latin, and French, by Peyrard	1814
(For other editions, see EUCLID.)	
——— Porisms, restored by Dr Simson, Opera quædam Reliqua	1776
Apollonius, Conics, and various works	fl. B. C. 244
For an account of his writings, see APOLLONIUS.	
Archimedes on the Sphere and Cylinder, &c.	born B. C. 287
First edition of Greek text by Venatorius,	1544
Oxford edition, Gr. and Lat., by Torelli,	1792
Edition in French, by Peyrard	1808
Eratosthenes, Geometria cum Annot. 1672	fl. B. C. 194
Theon, Commentator on Euclid	fl. B. C. 117
Theodosius, Sphericorum libri tres, printed at Oxford, 1707	fl. A. C. 75
Menelaus, Spherics, edited by Maurolycus	fl. A. C. 100
Serenus, De Sectione Cylindri et Coni	fl. A. C. 200
His treatise is in Oxford edition of Apollonius.	
Pappus, Mathematicæ Collectiones, 1588, 1660	fl. A. C. 380
Proclus, Commentator on Euclid	fl. A. C. 450
Taylor gave a translation in English, 1788.	
Veterum Mathematicorum Athenæi, Bitonis, Apollodori, Heronis, Philonis, et aliorum, Opera, Gr. et Lat	1693

Writers in Modern Times.

Lucas de Burgo, Summa de Arithmetica, &c	1494
Brauardinus, Geometria Speculativa	1495
Boville, L'Art et Science de Géométrie	1514
N. de Cusa, De Geometricis Transmutationibus	1514
Albert Durer, Institutionum Geometricarum lib. iv	1532
Orontius Fineus, Liber de Geometrica Practica	1544
Record, The Pathway to Knowledge	1551
Buteo, Opuscula quædam Geometrica	1554
Ramus, Arithmeticæ lib. ii. Geometricæ lib. xxvi	1580
Finckius, Geometriæ Rotundæ lib. iii	1583
Stevinus, Problematum Geometricorum lib. v	1583
Barotius, Geom. Problema Tredecem Modis Dem	1586
Vieta, Opera Mathematica	1589
Digges (Tho.), Pantometria, a geometrical treatise	1591
Baptista Porta, Elementorum Curvilineorum lib. ii	1601
Ramus, Geometria	1604
Clavius, Geometria Practica	1606
Ghetaldus, Apollonius Redivivus	1607
Anderson, Supplementum Apollonii Redivivi	1612
Kepler, Nova Stereometria, &c	1618
Van Ceulen, De Circulo et Adscriptis	1619
Snellius, Cyclometricus	1621
Metius, Arith. libri ii. et Geom. libri vi	1626
Guildin, De Centro Gravitatis, &c	1635
Cavalieri, Geometria Indivisibilibus promota	1635
——— Exercitationes Geometricæ sex	1647
Descartes, Geometria	1637
Toricelli, De Sphæra et Solidis Sphæralibus, &c	1644
Gregory St Vincent, Opus Geom. quadrat. Circuli.	1647
Rudd, Practical Geometry	1650
Wallis, Arithmetica Infinitorum	1656
——— De Cycloide et Cissoide	1659
Pascal (A. Dettonville), Lettres (on the Cycloid)	1658
Ricci, Exer. Geom. de Maximis et Minimis	1666
J. Gregory, Vera Circ. et Hyp. Quadratura	1667
